**Carboxylic acids.** KALLÉ & Co. A.-G. (Wilhelm Neugebauer, inventor). Ger. 472,606, Oct. 20, 1925. Carboxylic acids contg. S are prep'd. by the action of isatin, its substitution products, homologs, analogs or 2-derivs., on thioglycolic acids, especially in presence of a condensing agent. Thus, 15 parts of isatin and 17 parts of phenylthioglycolic acid are heated for 20 hrs. in a reflux condenser with 25 parts of anhyd. AcONa and 20 parts of glacial AcOH. The soln. is then diluted and filtered. The new acid is pptd. from the filtrate by HCl. It melts with decompn. at 293°, uncorrected. Other examples are given.

**2-Hydroxy-3-sulfo-6-naphthalenecarboxylic acid.** I. G. FARBENIND. A.-G. (Friedrich Krecke, inventor). Ger. 473,218, June 27, 1926. See U. S. 1,676,698 (C. A. 22, 3171).

**Substitution products of quinolinecarboxylic acids.** SCHERING-KAHLBAUM A.-G. (Max Dohrn and Albrecht Thiele, inventors). Ger. 472,821, May 23, 1926. Di- and poly-iodo substitution products of quinolinecarboxylic acids are prep'd. by the action of I on the acid in the presence of fuming H<sub>2</sub>SO<sub>4</sub>. Thus, a dry mixt. contg. 1 mol. of 2-phenylquinoline-4-carboxylic acid and 3 mols. of I is added to fuming H<sub>2</sub>SO<sub>4</sub> contg. 50% SO<sub>3</sub>, cooled, and placed for 9-10 hours in a water bath. Cooling yields triiodo-2-phenylquinoline-4-carboxylic acid contg. 60.8% I. If 1 mol. I is used, the diiodo product is formed. If 4 mols. of I are added, a pentaiodo product is formed. Monosulfo-2-phenylquinoline-4-carboxylic acid treated in the same way gives a similar series of iodo substitution products.

**Monocarboxylic acids from aldoses.** CHEM. FABRIK VORM. SANDOZ. Ger. 473,261, July 3, 1927. Addn. to 461,370. The method of Ger. 461,370 (see Brit. 289,280, C. A. 23, 606) is modified by treating the aldoses in alkali carbonate soln. with Cl in the presence of small amts. of compds. of Br or I. Cooling is then unnecessary. The prepn. of lactobionic and gluconic acids, which are isolated as Ca salts, is described by way of example.

**Salts of *o*-aminophenylpropionic acids.** I. G. FARBENIND. A.-G. (Fritz Mayer, inventor). Ger. 474,221, April 7, 1925. This corresponds to Brit. 250,250 (C. A. 21, 916) but gives addnl. examples describing the prepn. of Na 6-methyl-1-aminophenyl-2-propionate, 1- $\beta$ -aminophenylbutyrate and 5,6-diaminophenyl-1,4-dipropionate.

**Nitrophenyloxamic acids.** COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUF. DE PRODUITS CHIM. DU NORD RÉUNIES, ÉTABLISSEMENTS KUELMANN. Fr. 649,328, Feb. 20, 1928. Nitrophenyloxamic acids are prep'd. by heating nitroanilines (*o*-, *m*- or *p*-) or nitroanilines substituted in the ring, with an excess or anhydrous oxalic acid, taking care to eliminate from the reaction water as it is formed and to have the reagents carefully mixed. Thus, *p*-nitroaniline is carefully mixed with anhydrous oxalic acid and heated to 125-135° for 12 hrs. with constant stirring. The *p*-nitrophenyloxamic acid may be reduced to the amino compd. The *o*- and *m*- compds. and *p*-amino-*m*-chlorophenyloxamic acid may be prep'd. in the same way.

**Sulfonic acids.** I. G. FARBENIND. A.-G. (Karl Daimler and Gerhard Balle, inventors). Ger. 472,959, April 16, 1926. Aralkyl-aryl sulfonic acids are prep'd. by the interaction of aromatic hydrocarbons, aralkyl halides and H<sub>2</sub>SO<sub>4</sub>. Thus, molten naphthalene, benzyl chloride and H<sub>2</sub>SO<sub>4</sub> at 80-85° give benzylnaphthalenesulfonic acid. Other examples are given.

**Sulfamic acids.** I. G. FARBENIND. A.-G. Brit. 298,550, July 8, 1927. See Fr. 638,175 (C. A. 23, 154).

**Diazosulfamic acids.** I. G. FARBENIND. A.-G. (Karl Schirmacher and Werner Schirmacher, inventors). Ger. 473,217, Feb. 23, 1926. This corresponds to Brit. 266,388 (C. A. 22, 690) but gives addnl. examples.

**Adipic acid.** DEUTSCHE HYDRIERWERKE A.-G. Ger. 473,960, Feb. 13, 1926. Adipic acid and its alkyl substitution derivs. are prep'd. by oxidizing hydrogenated phenols in the presence of O carriers in the usual way. Thus, cyclohexanol is dropped slowly into 50% HNO<sub>3</sub> contg. a small quantity of NH<sub>4</sub>VO<sub>3</sub> at 50°. The mother liquor contains a good yield of adipic acid and small quantities of succinic and glutaric acids. Also, an air current contg. methylcyclohexanol is passed over HVO<sub>2</sub> at 300-400°. A good yield of methyladipic acid is produced. Other examples are given.

**Hydroaromatic dicarboxylic acids.** DEUTSCHE HYDRIERWERKE A.-G. Ger. 474,985, June 23, 1926. Addn. to Ger. 473,960 (cf. preceding abstr.). Hydrogenated phenols are substituted by wholly or partially hydrogenated cyclic alcs. or ketones and the oxidation is continued until the corresponding dicarboxylic acid is formed. Thus,

800 g. decahydronaphthol is warmed to 50° with 3.5 kg. 60%  $\text{HNO}_3$  and  $\text{NH}_4$  vanadate. The product contains a mixt. of *cis*- and *trans*-hexahydro-*o*-phenylenediacetic acid of m. p. 164 and 151°, and octahydrocinnamic-*o*-carboxylic acid.

**Barbituric acid.** F. HOFFMANN-LA ROCHE & Co. A.-G. Ger. 474,664, Dec. 7, 1924. Addn. to Ger. 471,655 (C. A. 23, 2449). A deriv. of isopropylallylbarbituric acid is prepd. by mixing the acid with 1-phenyl-2,3-dimethyl-4-dimethylamino-5-pyrazolone in suitable solvents in mol. proportions, and crystallizing out. Thus, the two substances are dissolved in  $\text{C}_6\text{H}_6$  and heated in a reflux condenser. The new deriv. appears as yellow crystals on cooling. Other solvents mentioned in examples are water, alc. and acetone.

**Succinic acid.** VEREIN FÜR CHEM. IND. A.-G. Ger. 473,262, Dec. 19, 1926. Succinic acid is prepd. by oxidizing butyrolactone, valerolactone, or a mixt. of the 2 lactones with  $\text{HNO}_3$  in great excess at a temp. below 20°.

**Tartaric acid.** ALFRED NOWAK. Austrian 112,461, Aug. 15, 1927. Tartaric acid is extd. from crude aq. solns. by means of a water-insol. org. solvent, e. g.,  $\text{C}_6\text{H}_{11}\text{OH}$ ,  $\text{C}_6\text{H}_{13}\text{OH}$ ,  $\text{Pr}_2\text{O}$ ,  $\text{Bu}_2\text{O}$ ,  $(\text{C}_6\text{H}_{11})_2\text{O}$ , or a high-boiling fatty acid, and the acid is re-extd. from this soln. by means of water. A purer product is obtained if the org. solvent soln. is dried before re-extg. with water.

**Naphthylthioglycolic acid.** SOC. ANON POUR L'IND. CHIM. À BAËLE. Ger. 474,560, Oct. 15, 1926. The chloro substitution products of a halide of this acid are prepd. by treating with Cl or such substances as  $\text{SO}_2\text{Cl}_2$ . Thus, 218 parts of 1-naphthylthioglycolic acid is suspended in 600 parts of  $\text{PhCl}$  and 140 parts  $\text{PCl}_5$  added. The mixt. is maintained at 70–80° for some hours. The 1-naphthylthioglycolyl chloride soln. obtained is diluted with 400 parts of  $\text{PhCl}$ , and 3 parts  $\text{SbCl}_5$  added. The temp. is kept at 0–5° while 140 parts of  $\text{SO}_2\text{Cl}_2$  is added in drops and the chloro-1-naphthylthioglycolyl chloride so formed removed by  $\text{Na}_2\text{CO}_3$  soln. The excess of  $\text{PhCl}$  is removed by steam. Another example is given.

**2,3-Aminonaphthoic acid.** I. G. FARBENIND. A.-G. Fr. 648,803, Feb. 7, 1928. See Brit. 284,998 (C. A. 22, 4540).

**2,4'-Dihalo-5'-methyl-*o*-benzoylbenzoic acids.** ROGER ADAMS (to Newport Co.). U. S. 1,711,164, April 30. These compds., e. g., the dichloro compd., may be formed by condensing a 2,4-dihalotoluene with phthalic anhydride (suitably with  $\text{AlCl}_3$  or  $\text{FeCl}_3$ ); they are dye intermediates. The dichloro compd. m. 140° and forms white crystals.

**Saponification of ethylsulfuric acid.** COMPAGNIE DE BÉTHUNE. Ger. 474,502, July 31, 1924. The process is carried out in a continuous distn. column. Steam and  $\text{NH}_3$  are admitted in the lower half of the column and  $\text{EtHSO}_4$  in the upper half, so that the acid and saponig. agents flow in opposite directions in the column.

**Acetic anhydride and similar anhydrides.** BRITISH CHELANESE, LTD., H. DREYFUS and C. I. HANEY. Brit. 298,667, July 14, 1927.  $\text{Ac}_2\text{O}$  and other aliphatic anhydrides are formed by heating the vapors of the corresponding acids (which may be dil.) and the anhydrides are condensed and sepd. from assocd.  $\text{H}_2\text{O}$  by passing the vapors under the surface of a cooled "extraction liquid" such as  $\text{C}_6\text{H}_6$ ,  $\text{CHCl}_3$ , mixts. of ether,  $\text{CHCl}_3$ , and gasoline or similar hydrocarbon material. Various details are given and an app. is described.

**Alcohols.** DEUTSCHE ERDÖL A.-G. (Wilhelm Roederer, inventor). Ger. 474,640, Dec. 31, 1921. High-mol. alcs. are obtained from lignite bitumen by treating with aq. alkali soln. with or without pressure, and extg. Thus, 100 kg. montan wax is heated for 2 hrs. under a pressure of 2 atm. with  $\text{NaOH}$ . On cooling, the mass is ground up and extd. with  $\text{C}_6\text{H}_6$ . On evapg. the  $\text{C}_6\text{H}_6$ , montan alcohol remains as a brown plastic mass, m. 60°.

**Alcohols and ammonia.** SOC. CHIM. DE LA GRANDE PAROISSE, AZOTE ET PRODUITS CHIM. Fr. 649,711, July 15, 1927. A mixt. of CO, N and H is passed to a plant for producing alc. (e. g.,  $\text{MeOH}$ ), then to an  $\text{NH}_3$  plant and the residual gases are returned to the stream of gas to the alc. plant.

**Ethylene.** LOUIS AGNUS. Fr. 648,340, June 16, 1927.  $\text{C}_2\text{H}_4$  is obtained by passing a mixt. of  $\text{CS}_2$  and  $\text{CH}_4$  through a heated zone, preferably over pumice stone or active C and substances which will combine with S, such as Cu or Zn.

**Acetylene.** ALFRED SCHROEDER. Ger. 472,976, May 13, 1927. A safety app. for the drying and purification of  $\text{C}_2\text{H}_2$  is described.

**Terpene.** WALTHER STRAUB. Ger. 472,540, Dec. 18, 1927. Terpene-like hydrocarbons are extd. from juniper-berry oil by 65% alc. The alc. ext. is sepd. from the residue by fractional distn.

**Acetone.** I. G. FARBENIND. A.-G. Brit. 299,048, Oct. 21, 1927.  $\text{C}_2\text{H}_5$  and steam

are passed over catalysts comprising metals or compds. of metals, the acetates of which produce acetone when heated and the rate of flow of the gaseous mixt. is kept lower than that which yields  $\text{AcH}$  as the main product. As catalysts, there may be used oxides, carbonates and acetates of the alk. earth metals, Zn, Sn, Al and Mg, or basic salts of these metals or compds. which during the reaction are converted into oxides, carbonates or acetates, these metals themselves, or finely divided Pb or Fe, calamine or bauxite,  $\text{V}_2\text{O}_5$ ,  $\text{MnO}_2$ , Cr-Tl compds., or various mixts. of these. Catalyst poisons such as P and As compds. should be excluded as should also  $\text{Fe}_2\text{O}_3$ , Th oxide and double salts of Th with alkali and alk. earth metals. The catalyst may be regenerated by use of air or O and steam. A temp. of 400-450° is suitable for the acetone-producing reaction.

**Aminoanthraquinone.** I. G. FARBENIND. A.-G. (Hermann Berthold, inventor). Ger. 473,871, Dec. 3, 1925. See U. S. 1,691,428 (C. A. 23, 395).

**1-Methyl-2,4-dihaloanthraquinone.** ROGER ADAMS (to Newport Co.). U. S. 1,711,165, April 30. These compds., e. g., the dichloro compd., may be formed by treating 2',4'-dihalo-5'-methyl-*o*-benzoylbenzoic acid with  $\text{H}_2\text{SO}_4$  at 100°; they are dye intermediates. The dichloro compd., m. 155°.

**Dinaphthylene dioxide quinone.** I. G. FARBENIND. A.-G. Brit. 298,640, Oct. 13, 1927. An oxidation product of 1,1'-dinaphthylene 2,8',8,2'-dioxide, apparently the 4,4'-quinone, is obtained as a red-brown powder (giving a yellow leuco compd with alkali hyposulfite) by oxidizing the dinaphthylene dioxide with chromic acid (which may be formed from  $\text{K}_2\text{Cr}_2\text{O}_7$  and  $\text{H}_2\text{SO}_4$ ) in aq. suspension.

**5-Iodo-2-aminopyridine.** SCHERING-KAHLBAUM A.-G. (Otto von Schickh, inventor). Ger. 473,213, Apr. 13, 1927. See Brit. 288,571 (C. A. 23, 613).

**Dimethyl, methylene, and chloromethyl sulfates; chloromethyl sulfate chloride; dichlorodimethyl ether, etc.** K. FUCHS and E. KATSCHER. Brit. 299,064, Oct. 21, 1927. Halogen or sulfuric acid or halogen and sulfuric acid derivs. of "functional derivs." of  $\text{CH}_2\text{O}$  (which are defined as substances contg.  $\text{CH}_2$  not directly combined with C such as methylene ether, dichlorodimethyl ether, methylene esters such as the dichloride, sulfate and acetate, and Schiff's bases of  $\text{CH}_2\text{O}$ ) are produced by treating  $\text{CH}_2\text{O}$  or its polymers or "functional derivs." with halosulfonic acid, preferably chlorosulfonic acid or its salts, esters or components. Numerous details of procedure are given.

**Cysteine hydrochloride.** SCHERING-KAHLBAUM A.-G. Ger. 472,822, June 9, 1927. Cysteine-HCl, entirely free from metal, is prepd. by repeatedly triturating the crystals of the substance with acetone. Thus, cystine is reduced with Sn and  $\text{H}_2\text{S}$ . The soln. is then freed from the reducing agents and the cysteine-HCl crystd. out. The crystals are ground in a mortar with pure acetone until the acetone remains colorless.

**Pinene sulfate.** GEZA AUSTERWEIL. Ger. 473,330, Jan. 31, 1926. Turpentine oil or nopinene is treated with aq.  $\text{H}_2\text{SO}_4$  at a low temp. and the reaction mixt. is poured into water. An oily hydrate seps. and is removed, and the ester is then salted out from the aq. residue.

**Chloranil and bromanil.** L. B. HOLLIDAY & Co., LTD. and CECIL SHAW. Fr. 648,850, Sept. 5, 1927. See Brit. 274,700 (C. A. 22, 2172).

**Yellow phenolphthalein.** JOSEPH EBERT (38.33% to Whitney Payne, and 38.33% to Randall Anderson). U. S. 1,711,048, April 30. A yellow amorphous phenolphthalein having an ash content not exceeding 0.05% and a m. p. of not less than 256° is obtained by extg. partially purified yellow amorphous phenolphthalein with a solvent such as  $\text{AmOH}$  or  $\text{BuOH}$ .

**Films from urea-aldehyde condensation products.** WOLFF & Co. and R. WEINGAND. Brit. 298,631, Oct. 14, 1927. Films or "foils" are formed from a mixt. of a plasticizing agent such as glycerol or glycol with a condensation product of an aldehyde and urea or a deriv; the mixt. while liquid is applied to a suitable base and removed after solidification.

**Condensation products of hydroaromatic ketones.** I. G. FARBENIND. A.-G. Fr. 648,940, Feb. 11, 1928. New condensation products are obtained by heating to high temps. and in the presence of an acid condensing agent, primary, secondary or tertiary aromatic amines having the position *p*- to the N free, or their substitution products, with cyclic hydroaromatic ketones or their substitution products. The products obtained have in general 3 rings, but further heating gives products having only 2 rings. Thus, cyclohexanone is heated to 140-150° with  $\text{PhNH}_2$  and  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$ , yielding a compd. having 3 rings, m. 111° and  $b_D^{25}$  275-276°. On further heating with  $\text{H}_2\text{SO}_4$  an insol. sulfate is obtained, the base of which contains 2 rings,  $b_D^{170}$  170-171°.

and can be diazotized and coupled with 2-naphthol-3,6-disulfonic acid to give a red-violet *azo dye*. Examples are also given of the production of compds. when  $\text{PhNH}_2$  is replaced by *o*-chloroaniline, *o*-toluidine, *o*-anisidine, monoethyl-*o*-toluidine,  $\text{PhNMe}_2$ , and when methylcyclohexanone is used.

## 11—BIOLOGICAL CHEMISTRY

PAUL E. HOWE

A—GENERAL

FRANK P. UNDERHILL

**Enzymic oxidation of oxalic acid by higher plants.** V. ZALESSKII AND A. KUKHAR-KOVA. *Ukrainskii Khim. Zhurnal* 3, Pt. sci. 139-52(1928).—The velocity of aerobic or anaerobic oxidation of oxalic acid by wheat seeds, as measured by the quantity of  $\text{CO}_2$  produced, is unaffected by the addn. of H acceptors, such as methylene blue,  $\text{KNO}_3$  and  $\text{H}_2\text{O}_2$ , while quinone and hydroquinone have a distinctly inhibitory influence on oxalase, the enzyme responsible for this oxidation. The inhibitory action of the latter is due probably to their greater affinity for O, the supply of which is thereby greatly diminished for the oxidation of oxalic acid. Cyanides and ethyl urethan do not inhibit the action of this enzyme, showing that neither surface action nor active centers contg. Fe are responsible for its action. KI has a marked inhibitory influence, probably as a result of combination with the enzyme. It is concluded that, in spite of the above observations, oxalase is a dehydrogenase, able to use only mol. O as a H acceptor.

B. C. A.

**Living matter.** WM. B. HARDY. *Colloid Symposium Monograph* 6, 7-16(1928).—Nothing is gained by claiming living matter as colloidal, for at present the colloidal kingdom "seems to be an Alsatia wherein difficult states of matter find refuge from a too exacting inquiry." After reviewing some of the aspects of living matter, H. suggests that the ideal "biological college" should have departments of mol. physics, cell mechanics, and biophysics, the last being the connecting link between the others.

JEROME ALEXANDER

**Cataphoresis of blood cells and inert particles in sols and gels and its biological significance.** HAROLD A. ABRAMSON. *Colloid Symposium Monograph* 6, 115-30 (1928). The following were experimentally followed: cataphoresis of single cells in horse serum; influence of particle shape on cataphoresis; relationship between endosmotic and cataphoretic velocity, migration of inert particles and blood cells in gelatin sols and gels; adsorption of proteins by quartz and glass.

JEROME ALEXANDER

**Continued studies on the problem of the specificity of enzyme complexes which split polypeptides.** EMIL ABDERHALDEN AND FRITZ REICH. *Univ. Halle. Fermentforschung* 10, 319-29(1929).—Several peptides contg.  $\beta$ -alanine were prepd. to det. the influence of this biologically foreign (fremdartig) amino acid on enzymic cleavage. The models studied include peptides representing both types of acid amide linkage of the  $\beta$ -alanine to the natural amino acid component, *i. e.*, through the amino and through the carboxyl of the  $\beta$ -alanine. Previous expts. have shown that these 2 types behave differently toward trypsin-kinase, those in which the foreign component carries the free carboxyl being resistant to enzymic cleavage. *Chloroacetyl-dl-leucyl- $\beta$ -alanine*, m. 124-6°, was prepd. in the usual way by coupling *dl*-leucyl- $\beta$ -alanine with  $\text{ClCH}_2\text{COCl}$  in the presence of NaOH. Treatment of this with 25%  $\text{NH}_4\text{OH}$  4 days at 37° yielded 60% of *glycyl-dl-leucyl- $\beta$ -alanine*, m. 160°, which gave both ninhydrin and biuret reactions.  *$\beta$ -Alanyl-dl-leucine*, m. 245-6° (decompn.), was obtained by coupling *dl*-leucine with an impure prepn. of  $\text{ICH}_2\text{CH}_2\text{COCl}$  and treating the crude intermediate with  $\text{NH}_4\text{OH}$ . Ninhydrin reaction was positive; biuret and carbonyl reactions were negative.  *$\beta$ -Alanylglycyl-dl-leucine*, which sinters 60° and decompn. 125°, was prepd. by coupling *glycyl-dl-leucine* with  $\text{ICH}_2\text{CH}_2\text{COCl}$  and aminating the intermediate iodo-propionyl deriv. (m. crude 170°). It gave positive ninhydrin and biuret reactions. The tetrapeptide,  *$\beta$ -alanyl-dl-leucylglycyl-dl-leucine*, amorphous, sinters 60°, decompn. 125°, was prepd. in the same way from *dl*-leucylglycyl-dl-leucine and  $\text{ICH}_2\text{CH}_2\text{COCl}$  and treatment of the intermediate viscous product with  $\text{NH}_4\text{OH}$ . Biuret and ninhydrin reactions were positive. All of these peptides with the exception of  *$\beta$ -alanyl-dl-leucine* were hydrolyzed by *N* NaOH at 37-40°; *glycyl-dl-leucyl- $\beta$ -alanine* more rapidly than its isomer  *$\beta$ -alanylglycyl-dl-leucine*. All were completely resistant to erepsin. Trypsin-kinase gave an appreciable hydrolysis only with the tetrapeptide. A. W. Dox

Further studies on the relations between substrate and enzyme complex based on the influence of erepsin and trypsin-kinase on polypeptides and related compounds. EMIL ABDERHALDEN AND HANS BROCKMANN. Univ. Halle. *Fermentforschung* 10, 380-40 (1929).—In general it appears that erepsin hydrolyzes only those peptides which carry a free  $\text{NH}_2$  group, and trypsin-kinase only those in which a free  $\text{CO}_2\text{H}$  group is present. New peptides are now described in which the  $\text{NH}_2$  group bears a substituent acyl or alkyl, or the  $\text{COOH}$  is present as an anilide grouping. In one instance both  $\text{NH}_2$  and  $\text{COOH}$  groups are thus substituted. These derivs. were examd. with respect to their behavior toward enzymes. *Butyldiglycylglycine*, m.  $231-2^\circ$ , was obtained by acylation of the tripeptide with  $\text{PrCOCl}$ . *N-Methyl-dl-leucyldiglycylglycine* (I), m.  $238^\circ$  (decompn.), was prepd. in 63% yield from *dl*- $\alpha$ -bromoisocapronyldiglycylglycine by 3-day treatment at  $37^\circ$  with 25%  $\text{MeNH}_2$ . It gives a red biuret reaction and is acid to litmus. *d*- $\alpha$ -Bromoisocapronylglycyl-*d*-alanyl-*l*-leucylglycyl-*d*-alanine (II), m.  $206-7^\circ$ ,  $[\alpha]_D^{20} -9.95^\circ$ , was obtained by acylation of the pentapeptide with *d*- $\text{Me}_2\text{CHCH}_2\text{CHBrCOCl}$ . *dl*- $\alpha$ -Bromoisocapronyltriglycylaniline, m.  $220-30^\circ$  (decompn.), was prepd. by shaking *dl*- $\alpha$ -bromoisocapronyltriglycyl chloride 2 hrs. with  $\text{PhNH}_2$ . Amination by a satd. soln. of  $\text{NH}_3$  in a mixt. of pyridine and  $\text{MeOH}$  5 hrs. at  $70^\circ$  and then 14 hrs. at  $38^\circ$  converted it into *dl*-leucyltriglycylaniline (III), m.  $160^\circ$  (decompn.). This gives positive ninhydrin and biuret reactions, and forms an oily picrate. Benzoyl-*dl*-leucylglycylaniline, m.  $197.5^\circ$ , was prepd. by refluxing the benzoyldipeptide 10 hrs. with  $\text{PhNH}_2$ ; butyryltriglycylaniline, m.  $231-2^\circ$ , by a similar treatment of the butyryltripeptide. Erepsin at  $p_{\text{H}}$  7.8 and  $38^\circ$  hydrolyzed III but not I and II. Trypsin-kinase at  $p_{\text{H}}$  8.4 and  $38^\circ$  hydrolyzed II but not I and III. Enzyme expts. with the other new derivs. are not reported. A table summarizes the results of expts. with a no. of previously described peptide derivs., mainly halogenacylpeptides, which as a rule are attacked by trypsin-kinase but not by erepsin. A. W. Dox

Continued studies on the problem of the specificity of enzyme complexes which split polypeptides. EMIL ABDERHALDEN AND FRIEDRICH SCHWETZER. Univ. Halle. *Fermentforschung* 10, 341-64 (1929).—The following polypeptides and derivs. thereof were prepd. by the customary methods, those with stated m. p. being new substances: *dl*-leucylglycylglycine (I) (Bz deriv., m.  $175^\circ$  with decompn., *PhNCO* deriv., m.  $185^\circ$ ,  $\beta\text{-C}_{10}\text{H}_{17}\text{SO}_2$  deriv., m.  $175^\circ$  with decompn.); glycyl-*dl*-phenylalanine (II); diglycyl-*dl*-phenylalanine (III); chloroacetyldiglycyl-*dl*-phenylalanine, m.  $184-5^\circ$  (decompn.); diglycylglycyl-*dl*-phenylalanine (IV), m.  $223^\circ$  (decompn.); *dl*-phenylalanylglycine (V); *dl*-phenylalanylglycylglycine;  $\beta$ -phenyl- $\alpha$ -bromopropionylglycylglycine, m.  $278-9^\circ$  (decompn.); *dl*-phenylalanyldiglycylglycine (VI), m.  $207^\circ$  (decompn.); *PhNCO* deriv. of VI, m.  $296^\circ$  with gas evolution;  $\beta$ -phenyl- $\alpha$ -bromopropionylglycylphenylalanine, m.  $187^\circ$  (decompn.); *dl*-phenylalanyltriglycyl-*dl*-phenylalanine (VII); *dl*-leucylglycyl-*dl*-phenylalanine (VIII), m.  $235^\circ$ ; *dl*- $\beta$ -phenyl- $\alpha$ -bromopropionylglycyl-*dl*-leucine (IX), m.  $161^\circ$ ; *dl*-phenylalanylglycyl-*dl*-leucine (X), m.  $210^\circ$  (decompn.); *dl*- $\beta$ -phenyl- $\alpha$ -bromopropionylglycyl-*dl*-phenylalanine, m.  $174-5^\circ$ ; *dl*-phenylalanylglycyl-*dl*-phenylalanine (XI), m.  $236^\circ$  (decompn.); *dl*- $\beta$ -phenyl- $\alpha$ -bromopropionyl-*dl*-phenylalanine (XII), m.  $69-70^\circ$ ; *dl*-phenylalanyl-*dl*-phenylalanine (XIII). I is hydrolyzed by erepsin but not by trypsin-kinase; all 3 of its derivs. are hydrolyzed by trypsin-kinase but not by erepsin. *N* NaOH at  $37^\circ$  attacks the *PhNCO* deriv. most readily, then the Bz deriv., while the  $\beta\text{-C}_{10}\text{H}_{17}\text{SO}_2$  deriv. is hydrolyzed only slowly. Substitution in the  $\text{NH}_2$  group of a polypeptide alters the character of the whole mol., but the effect varies with different substituents and with different peptides. *N* NaOH scarcely affects XII and XIII in 5 days, hydrolyzes II slowly, III more rapidly, and IV very much more rapidly. Of those peptides with a terminal phenylalanyl V is most slowly and VI most rapidly hydrolyzed. VII is also hydrolyzed rapidly. Of the 2 isomers, VIII and X, the latter undergoes cleavage somewhat more readily. Although XIII is very resistant, this is not true of XI with its intermediate glycyl. Erepsin attacked all the polypeptides contg. phenylalanine (XIII) was not tested because of its insol., but not the haloacyl derivs. Trypsin-kinase attacked IV, VII, IX, X, XI, and XII. No polypeptide in which glycine carried the free  $\text{COOH}$  was attacked by trypsin-kinase. A. W. Dox

Further studies on the relations between substrate and enzyme complex based on the influence of erepsin and trypsin-kinase on polypeptides of definite composition. EMIL ABDERHALDEN AND VLASSIOS VLASSOPOULOS. Univ. Halle. *Fermentforschung* 10, 365-95 (1929).—Three series of glycine polypeptides contg., resp.,  $\alpha$ -aminobutyric acid, valine and norvaline were prepd. by the usual methods and subjected to tests of enzymic hydrolysis. *dl*- $\alpha$ -Bromobutyrylglycine, m.  $106.5^\circ$ , was prepd. by coupling glycine with  $\text{EtCHBrCOBr}$ . A much better yield was consistently obtained from synthetic glycine than from the glycine of hydrolyzed silk. Amination with 25%

NH<sub>4</sub>OH converted it into 60% *dl*- $\alpha$ -aminobutyrylglycine (I) (*PhNCO* deriv. m. 188°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 165.5°). In the same way glycylglycine was coupled with EtCHBrCOBr to *dl*- $\alpha$ -bromobutyrylglycylglycine, m. 147°, and the latter aminated to 40% *dl*- $\alpha$ -aminobutyrylglycylglycine (II) (*PhNCO* deriv. m. 172°,  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 140°); and diglycylglycine yielded 75% *dl*- $\alpha$ -bromobutyryldiglycylglycine, from which 60% *dl*- $\alpha$ -aminobutyryldiglycylglycine (III) was obtained (*PhNCO* deriv. m. 193°). Glycyl-*dl*- $\alpha$ -aminobutyric acid (IV) has previously been described (*PhNCO* deriv. m. 195°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 112-4°). This was coupled with ClCH<sub>2</sub>COCl to form *chloroacetyl-glycyl-dl*- $\alpha$ -aminobutyric acid, m. 120-1°, and the latter aminated to diglycyl-*dl*- $\alpha$ -aminobutyric acid (V) (*PhNCO* deriv. m. 208°). Norvaline was coupled with PrCHBrCOCl to an almost quant. yield of *dl*- $\alpha$ -bromovaleryl-*dl*-norvaline, m. 124-5°, and this was aminated to the dipeptide *dl*-norvalyl-*dl*-norvaline (VI), m. 270° with decompn. (*PhNCO* deriv. m. 206°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 177°). Further coupling with ClCH<sub>2</sub>COCl yielded *chloroacetyl-dl*-norvalyl-*dl*-norvaline, m. 147.5, which was aminated to glycyl-*dl*-norvalyl-*dl*-norvaline (VII), m. 238-40° (*PhNCO* deriv. m. 156°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 195°). Condensation of *d*-valine with *d*-PrCHBrCOCl yielded 93% *d*- $\alpha$ -bromovaleryl-*d*-valine, m. 137°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> 13.1°, which on amination with 25% NH<sub>4</sub>OH gave 40% of the racemic dipeptide and from the mother liquor 50% *dimethylacrylvaline*, m. 137°, was obtained. The yield of active dipeptide, *d*-valyl-*d*-valine, (VIII), m. above 300° [ $\alpha$ ]<sub>D</sub><sup>20</sup> -54°, was only 2%. By the use of liquid NH<sub>3</sub> in a sealed tube the yield of active dipeptide was increased to 6% and finally 10%, but here also there was considerable racemization (30%) and a 35% yield of *dimethylacrylvaline*. Attempts to obtain the active peptide through the ester and anhydride were unsuccessful, the intermediate Me ester, b<sub>17</sub> 58°, being optically inactive, and the yield of anhydride, m. 290°, very small. *PhNCO* deriv. of VIII, m. 184°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 213-5°; *PhNCO* deriv. of racemic dipeptide m. 188-9°;  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. m. 208°. Condensation of the active dipeptide with ClCH<sub>2</sub>COCl and amination of the oily product gave 43% glycyl-*d*-valyl-*d*-valine (IX), m. 220°, [ $\alpha$ ]<sub>D</sub><sup>20</sup> -32°, and 25% of the racemic tripeptide. The  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. of IX was prep'd. but its m. p. was not stated; prep'n. of the *PhNCO* deriv. was unsuccessful. Erepsin hydrolyzed the peptides I, IV, VI, VII, VIII, and IX, also the racemic forms of VI, VII and VIII, but II, III and V only very slightly. None was attacked by trypsin-kinase, and only the *PhNCO* deriv. of IV. *N* NaOH at 37° hydrolyzed I, II, III, IV and V; their *PhNCO* derivs. more readily but their  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> derivs. less readily than the free peptides. VIII and the corresponding *dl*-form remained unaltered, while their *PhNCO* and  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> derivs. showed cleavage. IX was hydrolyzed by NaOH. The *dimethylacrylvaline* was resistant to both NaOH and trypsin. In contrast to VIII the unbranched isomer VI was slowly attacked by NaOH, also its *PhNCO* and  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> derivs. Contrary to the general rule, the *PhNCO* deriv. of VII was hydrolyzed less rapidly than the free peptide or even its  $\beta$ -C<sub>10</sub>H<sub>7</sub>SO<sub>2</sub> deriv. A striking observation was the fact that the  $\alpha$ -bromoisovaleryl derivs. were far more difficult to aminate than the corresponding  $\alpha$ -bromonorvaleryl derivs., their reaction with NH<sub>4</sub>OH being much slower and less complete. A. W. DOX

Studies on the behavior of *N* alkali, erepsin and trypsin-kinase toward polypeptides containing 3,5-halogen substituted tyrosine, and toward glycyl-*d*-tyrosine, glycyl-*dl*-nitrotyrosine and glycyl-*dl*-*o*-tyrosine. EMIL ABDERHALDEN AND ADOLF SCHMITZ. *Univ. Halle. Fermentforschung* 10, 428-39 (1929).—New peptide derivs. described are glycyl-*d*-tyrosine, amorphous, sinters 120° m. 160° with foaming, which was obtained by coupling *d*-tyrosine ester with ClCH<sub>2</sub>COCl, saponig. and aminating; *chloroacetyl-dl*-3,5-dichlorotyrosine, m. 195°, obtained in 65% yield from the dichlorotyrosine Me ester and ClCH<sub>2</sub>COCl in CHCl<sub>3</sub> and aq. NaHCO<sub>3</sub>; glycyl-*dl*-3,5-dichlorotyrosine, m. 237°, in 60% yield by amination of the preceding with 25% NH<sub>4</sub>OH; and by analogous reactions, *chloroacetyl-dl*-3,5-dibromotyrosine, m. 207° (yield 55%); glycyl-*dl*-3,5-dibromotyrosine, m. 222-3° with decompn. (yield 70%); *chloroacetyl-dl*-3-nitrotyrosine, m. 166° (yield 60%); glycyl-*dl*-3-nitrotyrosine, m. 240° (decompn.); *chloroacetyl-dl*-*o*-tyrosine, amorphous, in 50% yield, from the free amino acid and ClCH<sub>2</sub>COCl; glycyl-*dl*-*o*-tyrosine, amorphous, sinters 120°, m. 150° (yield 40%); and by similar reactions between these glycyl-dihalotyrosines and *dl*-Me<sub>2</sub>CHCH<sub>2</sub>CHBrCOCl, and the usual amination; *dl*- $\alpha$ -bromoisopronylglycyl-*dl*-3,5-dichlorotyrosine (yield 65%); *dl*-leucylglycyl-*dl*-3,5-dichlorotyrosine, m. 210 with decompn. (yield 50%); *dl*- $\alpha$ -bromoisocapronylglycyl-*dl*-3,5-dibromotyrosine (yield 70%); *dl*-leucylglycyl-*dl*-3,5-dibromotyrosine, sinters 190°, m. 220° (decompn.); *dl*- $\alpha$ -bromoisocapronylglycyl-*dl*-3,5-diiodotyrosine (yield 60%); *dl*-leucylglycyl-*dl*-3,5-diiodotyrosine, darkens, 180°, m. 205° (foaming). All of these derivs. are hydrolyzed by *N* NaOH at 37°; those which contain 3 units are hydrolyzed most rapidly.

Glycyl-*l*-tyrosine is very slowly hydrolyzed, as is also glycyl-*o*-tyrosine. The rate of hydrolysis of substituted dipeptides follows the order:  $\text{NO}_2 < \text{Cl} < \text{Br} < \text{I}$ . Erepsin attacks only the dipeptides contg. the natural *l*-tyrosine or its halogen-substituted derivs. Trypsin-kinase attacks only the tripeptides. In general, substitution on the nucleus of tyrosine does not protect the peptide from enzymic hydrolysis. Chloroacetyl-*o*-tyrosine is attacked by trypsin-kinase but not by erepsin. A. W. DOX

Further observations on the relations between the enzyme complexes erepsin and trypsin-kinase and the polypeptides and derivatives which they hydrolyze. Attempt to isolate erepsin from intestinal secretion and trypsin from pancreatic juice. EMIL ABDERHALDEN AND ERNST SCHWAB. Univ. Halle. *Fermentforschung* 10, 440-5 (1929).—Haloacyl derivs. of  $\alpha$ -amino acids are hydrolyzed by trypsin-kinase but not by erepsin which has been freed from trypsin. A surprising observation is that such derivs. are hydrolyzed more readily by erepsin contg. a small amt. of trypsin than by the same amt. of trypsin alone. Addn. of erepsin to the trypsin-kinase hastens the onset of hydrolysis so that during the first few hrs. the extent of cleavage is much greater, but gradually the control expt. with trypsin-kinase alone gains in velocity and the final result is the same in both cases. Chloroacetyl-*l*-leucine is slightly attacked by erepsin preps. in which trypsin cannot be demonstrated; hence the latter is presumed to be present in traces insufficient to hydrolyze the other less sensitive halogenacylamino acids. Several possible explanations of this phenomenon are suggested: the formation of an erepsin-trypsin-kinase complex with heightened activity, the destruction of inhibitory substances by the erepsin, and a coenzymic action. Certain exts. of powdered pancreas, pancreatin and especially pancreatic juice obtained by means of a fistula were found to be more active than purified trypsin-kinase toward acyl derivs. of amino acids. This also suggests the activation by erepsin. The difficulties experienced in isolating erepsin from intestinal secretion and trypsin from pancreatic juice are discussed. A. W. DOX

Continued studies on the problem of the specificity of enzyme complexes which split polypeptides. Experiments with polypeptides containing histidine. EMIL ABDERHALDEN, RICHARD FLEISCHMANN AND WILHELM IRION. Univ. Halle. *Fermentforschung* 10, 446-54 (1929).—The  $\text{HgCl}_2$  method of prepg. *l*-histidine from hydrolyzed blood corpuscles is considered more satisfactory than the recently described  $\text{Ag}_2\text{O}$  method of Vickery and Leavenworth (*C. A.* 22, 4140). It is less costly, less devious and time-consuming, and gives a better yield. From 5 l. of horse blood 58 g. histidine-HCl was obtained. A redetn. of the diamino acids in crystd. oxyhemoglobin gave the values: histidine 7.5-7.6%, lysine 8.15-8.25% and arginine 3.45-3.60%. These values should supersede those previously reported (*Z. physiol. Chem.* 37, 484). *l*-Histidine Me ester was coupled with *d*- $\text{Me}_2\text{CHCH}_2\text{CHBrCOCl}$  and the resulting ester sapond. to *d*- $\alpha$ -bromoisocapronyl-*l*-histidine (I), which was then aminated by 25%  $\text{NH}_4\text{OH}$  to *l*-leucyl-*l*-histidine (II), by the procedure of Fischer and Cone (*C. A.* 3, 314). I is quite unstable to alkali and the yield is much improved by sapon. the ester with 0.1 *N* instead of *N* NaOH. Both erepsin and trypsin-kinase hydrolyze the dipeptide II. I is slightly attacked by trypsin-kinase but not by erepsin. The relative stability toward trypsin-kinase of this bromoisocapronyl deriv. and of the bromoisovaleryl derivs. of other amino acids, as compared to the corresponding chloroacetyl and bromopropionyl derivs., suggests a stabilizing influence due to the branching of the chain. On the other hand, this substance is hydrolyzed by *N* and even by 0.1 *N* NaOH with unusual rapidity, although the dipeptide is quite resistant. The *dl*-bromoisocapronyl and *dl*-leucyl derivs. of *l*-histidine showed the same behavior toward enzymes and alkali as the optical forms above mentioned. A. W. DOX

The influence of formalin fixation of organs on the extractability of the lipids. MILOŠ MLADENović AND HANS LIEB. Univ. Zagreb and Univ. Graz. *Z. physiol. Chem.* 181, 221-6 (1929).—The Soxhlet extn. of  $\text{Et}_2\text{O}$ -sol. substances from dried powd. liver is complete in 8 hrs., whether the powder is prepd. from fresh tissue or from tissue preserved in formalin; a 50-hr. extn. does not increase the yield. Preps. from fresh liver, however, may yield 33% more  $\text{Et}_2\text{O}$  ext. and 100% more EtOH ext. than similar preps. from liver preserved in formalin. The N, P, cholesterol and neutral fat contents of the  $\text{Et}_2\text{O}$  ext. from untreated liver are also considerably higher. However, the  $\text{Et}_2\text{O}$  ext. from  $\text{CH}_2\text{O}$ -fixed tissue is completely sol. in MeAc while that from the non-treated tissue contains as much as 10% of material insol. in MeAc. Probably the  $\text{CH}_2\text{O}$  treatment results in some decompn. of phosphatides. A. W. DOX

The nature of the proteases. II. Relation between the chemical properties of a series of pepsin preparations and their activity toward various proteins. I. A. SMORODINTSEV AND A. N. ADOVA. Univ. Moscow. *Z. physiol. Chem.* 182, 1-7 (1929); cf. *C. A.* 22, 3671.—The relationship, previously reported, between the  $\text{NH}_2 : \text{CO}_2\text{H}$

ratio in pepsin preps. and their activity toward casein holds also for edestin, gelatin, egg albumin and muscle protein. All pepsin preps., whether strongly or feebly active, digest casein 10–20 times as readily as edestin. Muscle protein is digested 3–4 times as readily as egg albumin under identical conditions. A. W. DOX

**The influence of hydrogen peroxide on peroxidase activity of water extract from plant material.** A. I. SMIRNOV. *Trudi Kuban. Selsk. Khoz. Inst. (Arb. Kuban. Landw. Inst.)*, **4**, 11–20 (1926); *Expt. Sta. Record* **58**, 624.—Five cc. of a 1% soln. of  $H_2O_2$  is detrimental when used all at once on 50 cc. of reaction material for the detn. of peroxidase, particularly when the reaction material itself contains even small portions of peroxidase. The detrimental influence of  $H_2O_2$  on peroxidase depends not upon the abs. amt. of peroxide but upon its concn. The effects of time and concn. are detailed. H. L. D.

**Prof. Dr. Oskar Loew. On his eighty-fifth birthday, April 2, 1929.** A. JACOB. *Z. angew. Chem.* **42**, 369–70 (1929). E. H.

**The influence of cholates and other capillary active substances on "Electrotonus."** N. SCHEINFINKEL. Univ. Bern. *Z. Biol.* **88**, 407–18 (1929).—Na cholate and decholin weakened the elec. flow at the cathode, while the flow at the anode remained unchanged. Similar results were obtained with caprylic alc. and optochin. Cholate increases the sensitivity in the cathode region of a polarized current. F. K.

**The precipitation of casein at the isoelectric point.** FERDINAND LEBERMANN. Univ. Basel. *Biochem. Z.* **206**, 56–9 (1929).—The buffering effect of cow milk is so great that it must be properly considered in pptg. the casein at the isoelec. point. Casein partly pptd. by means of standard acetate soln. removes H ions from the milk. The opt. pptn. of casein from skimmed milk takes place with an acid acetate mixt. of  $pH$  3.74, the final  $pH$  of the soln. being quite different from the isoelec. point ( $pH$  4.7) of pure casein. S. MORGULIS

**Mechanism of inhibition by fluoride and the dissociation curve of fluoromethemoglobin.** F. LIPMANN. Kaiser Wilhelm-Inst., Berlin-Dahlem. *Biochem. Z.* **206**, 171–85 (1929).—The inhibition of fermentation by F is reversible; the degree of inhibition at different F concns. agrees with the requirements of the mass-action law; and, finally, the inhibition increases with acidity. These findings are in agreement with the inhibition of the lipase, and are easily interpreted on the assumption of a chemical, easily dissociable combination between enzyme and F. It is shown, furthermore, that muscle respiration is much more sensitive to F than the lactic-acid formation. A study of the F methemoglobin dissocn. reveals that this follows the monomol. reaction methemoglobin + F ion  $\rightleftharpoons$  MF, the affinity increasing on the acid side as in the case of the enzyme. The oxidation of oxalic acid by  $KMnO_4$  is slowed down by the formation of complex Mn fluorides, also the decompn. of  $H_2O_2$  by tervalent Fe. S. MORGULIS

**Reactions of carbon monoxide with metal compounds of cysteine.** WERNER CREMER. Kaiser Wilhelm-Inst., Berlin-Dahlem. *Biochem. Z.* **206**, 228–39 (1929); cf. *C. A.* **23**, 1655.—Fe in an alk. soln. of cysteine forms a carbonyl compd., whereby 1 g. atom Fe combines with 2 mols. CO. Fe forms a similar combination with isocysteine. Co forms under these conditions a carbonyl compd. in which 1 g. atom CO combines with 1 mol. CO.Co-Fe-cysteine and the CO-Fe-isocysteine dissoc. in the light, the CO being reversibly split off. CO-Co-cysteine under the same conditions is not light sensitive. CO-Fe cysteine prepd. from *d*-cysteine rotates light to the right, the sp. rotation for the D-line being about  $600^\circ$ , or nearly 60 times as great as that for cysteine. CO-Co-cysteine has no measurable rotating power. The  $O_2$  transfer to cysteine by Fe is inhibited by the CO. S. MORGULIS

**The effect of caffeine on the water-binding capacity of colloids.** JÁNOS SZELŐCZÉY. "Pazmány Péter" Univ., Budapest. *Biochem. Z.* **206**, 290–300 (1929).—See *C. A.* **22**, 1078. S. MORGULIS

**The assumed salt hydrolysis of starch.** N. MALYSHEV. Karls-Univ., Prague. *Biochem. Z.* **206**, 401–9 (1929).—In sterilized starch solns., whether in water or in salt soln. of different concns., there has never been observed any hydrolysis. In unsterilized starch solns. there was occasionally a hydrolysis found, but usually when the sol starch in the prepn. of the starch soln. was greatly boiled for less than  $1/2$  hr. or was not boiled at all. The presence of  $O_2$  or passing air through the starch soln. for 15–60 mins had no effect on the hydrolysis. It is concluded that salt does not function as a diastatic enzyme but may play a role as coenzyme or complement. S. MORGULIS

**A note on Ammon's paper on the permeability of surviving animal membranes.** MATRICE JOWETT. Univ. Liverpool. *Biochem. Z.* **206**, 503–4 (1929).—Errors in com-

puting the diffusion coeffs. in Ammon's paper (*C. A.* 23, 164) are pointed out which have led to the conclusion that glucose diffuses 250-5000 times slower than water. By making proper corrections in Ammon's data, J. shows that the diffusion of glucose through muscle as compared to its diffusion into water is of the same order of magnitude as that of the lactate ion.

S. MORGULIS

Comparative studies on the influence of the mountain climate on the blood catalase. A. I. ALEKSEEV. Biochem. Inst. State Univ., Tashkent. *Biochem. Z.* 207, 28-38(1929); cf. *C. A.* 22, 4545.—After a 2 months' sojourn in the mountains (1500 m.) the blood catalase content and the no. of erythrocytes diminish in comparison with those expected at a low altitude. The diminution in catalase is especially marked in the first week after return from the mountains. The no. of erythrocytes diminishes regularly during 4 months.

S. MORGULIS

Salkowski's color test for cholesterol. V. I. NIKOLAEV AND S. A. KRASILEVSKA. Vsesoyuz Acad. Sci. *J. Russ. Phys.-Chem. Soc.* 60, 1211-6(1928).—The appearance of a red coloration on agitating a cholesterol soln. in  $\text{CHCl}_3$  with concd.  $\text{H}_2\text{SO}_4$  (Salkowski test) is due to the formation of cholesteryl acid sulfate. Equiv. wts. of 95%  $\text{H}_2\text{SO}_4$  and cholesterol dissolved in dry  $\text{CHCl}_3$  were mixed, dried first in an oven at 50-60°, then in a desiccator *in vacuo* over concd.  $\text{H}_2\text{SO}_4$ . After 2 days the ester obtained presented under the microscope a dark red, brittle, cryst. mass, m. 160°. A few crystals were redissolved in  $\text{CHCl}_3$ , the excess of the latter was removed by evaporation *in vacuo*, and the remaining thick, dark red soln. was placed in a crystallizer which was stoppered and paraffined. After several days the ester recrystd. in dark red plates, the m. ps. of the binary system cholesterol- $\text{H}_2\text{SO}_4$  were taken (with varying quantities of  $\text{H}_2\text{SO}_4$ ) by the capillary-tube method and also by a thermocouple; the *liquidus* and *solidus* lines were detd. It is a case of fusion of the first type (conforming to Roozeboom) which corresponds to solid solns. of 2 components. The reaction of ester formation from its components is slow; it can be accelerated by heating. The gradual discoloration of the crystals is due to absorption of atm. moisture and the consequent hydrolysis of the ester. If the partly discolored ester is dried, the dark red coloration reappears.

BERNARD NELSON

Effect of internal secretion and of vegetative poisons on the permeability of animal membranes. I. ERNST GELLHORN AND HILDE GELLHORN. Univ. Halle a. S. *Arch. ges. Physiol.* (Pflüger's) 221, 247-63(1928).—The permeability of muscle and skin membranes for sugar is increased by 1 to 1 million *l*-adrenaline, and by thyroxine and insulin. Pilocarpine increases, and atropine diminishes permeability.

G. H. SMITH

Some further experiments on the effect of radiation on dissolved substances. M. C. REINHARD AND K. L. TUCKER. *J. Cancer Research* 12, 289-93(1929).—Radiation of solns. causes changes in those solns. which cannot be ascribed entirely to the effect of the solvent because the amt. of change in a  $\text{CHCl}_3$  soln. of cholesterol depends on the state of the solute. Radiation produces in a water soln. of quinol more profound changes than would be expected by simple oxidation action of the solvent. Radiation of aq. sucrose solns. indicates that the effect is more complicated than simple inversion of sucrose to invert sugar.

H. G. WELLS

Lipase. H. V. RULER AND SVEN GARD. Stockholm Högskola. *Arkiv Kemi, Mineral. Geol.* 10A, No. 2, 1-7(1928).—Preliminary results are given which demonstrate the presence of lipase in horse and in rat serum acting on glycerol monobutyrates, and of lipase in rat liver acting on Et glycololate, Et acetate, and glycerol monobutyrates. Some preliminary results are given which indicate that hemolysis is a lipase action.

J. J. W.

Malt pectinase. J. J. WILLAMAN. N. Y. Expt. Sta., Geneva. *Arkiv Kemi, Mineral. Geol.* 10A, No. 3, 1-4(1928).—By use of the same methods on malt that had been used on fungi (cf. *C. A.* 21, 2916), several samples of pectinase were prepd. The most active prepn. was made by extg. with water, centrifuging, dialyzing through collodion, centrifuging, pptg. at 50% alc., making the filtrate up to 85% alc., filtering, and drying with acetone. The filtrate from the 85% alc. still contained pectinase precipitable by acetone.

J. J. WILLAMAN

Chemical studies on the denaturing of proteins. I. T. TADOKORO AND K. YOSHIMURA. *J. Faculty Agr. Hokkaido Imp. Univ.* 25, 117-32(1928).—(a) The oryzenin of rice was prepd., and then denatured in soln. by boiling and by freezing. The ash and S were less in the boiled, but greater in the frozen, than in the original part. Max. turbidity and surface tension were obtained at different acidities in the denatured part. The  $[\alpha]$  was lower, and the rate of destruction by ultra-violet light was greater, in the original. The amide and histidine N were high, and the lysine N was lower in the denatured. (b) The glycinin of soy bean was prepd. and then denatured in soln.

by boiling, by freezing, by super-heated steam, by gasoline and by benzine. The P was higher in the boiled and frozen than in the original, but lower in the others. The S was higher in the boiled and super-heated, but lower in the others, than in the original. The free amino N was greater in all the denatured, and especially so when denatured by super-heated steam, gasoline and benzine. The amide, arginine and histidine N were higher in all the denatured, and especially the arginine in the frozen. The soly. of glycinin in NaOH and in  $\text{Na}_2\text{CO}_3$  solns., acid and salt solns. decreased in the following order: original, frozen, boiled, benzine, gasoline, super-heated. (c) Whole soy beans were denatured by heating dry, by boiling, by freezing and by soaking in gasoline, and the distribution of the N was studied. Those heated dry showed a great increase in N insol. in water and in NaCl. The frozen showed a decrease in the N sol. in water and in NaCl, but an increase in the N sol. in NaOH. The boiled showed a decrease in N sol. in water and in NaCl, and an increase in N sol. in NaOH. Those treated with gasoline and with benzine showed about the same changes as the boiled, but to a less degree. II. T. TADOKORO AND S. WATANABE. *Ibid* 133-49.—Four pairs of Japanese river salmon were used in a study of their muscle proteins. One pair was kept in a cooler, one was frozen 3 times, one was salted for 6 months, one was smoked in the ordinary way, and the proteins were prepd. The myosin and myogen were decreased in all 3 denatured samples, and in the salted and smoked they existed to the extent of only 10% of the original. The muscle fiber (sarkolemma) from the denatured part contained less ash and P. The  $\text{NH}_2$ , arginine and histidine N were decreased in the denatured. The myosin and myogen from the denatured muscle in NaOH soln. required greater addn. of acid to produce max. turbidity and surface tension. These proteins also had a greater  $[\alpha]$ .

J. J. WILLAMAN

The chemical composition of wool with especial reference to the protein of wool-fiber (keratin). HEDLEY R. MARSTON. *Australia Council Sci. Ind. Research Bull.* No. 38, 36 pp. (1928).—Wools grown under a great variety of conditions in Australia, from various breeds of sheep, having spinning counts varying from 48 to 74, were investigated. No correlation was found between the nature of the fiber and the percentage or nature of the accompanying fats. In order to avoid errors in the analysis due to cleavage of S from wool by scouring, incomplete dehydration or inconstant salt formation, the wool samples (approx. 25 g.) were purified prior to the analysis by dehydration in abs. a.c., continuous extn. with abs. ether for 48 hrs., thorough washing in 95% alc., vigorous shaking in a 2-l. Erlenmeyer flask with at least 15 changes of tap water, drying for 24 hrs. at 40°, combing the fibers with a fine comb, equilibration with about 2 l. 0.01 N HCl for 12 hrs., washing with several changes of distd. water, oven drying at 100°, washing in 2 changes of abs. alc. and finally oven drying for 96 hrs. at 100°. The compns. of all the wool keratins were found to be identical within the limits of exptl. errors. Alterations in the exptl. technic of the Van Slyke method used in this work for sepg. the nitrogen of the keratin are described. Because of inherent errors in the method, the quantities of monamino acids thus estd. must be considered relative rather than abs. values. Therefore, in the following results, the figures for the cystine, tyrosine and tryptophan contents of wool keratin are considered exact; those for arginine, histidine and lysine, a very close estimate: cystine, 13.1%; tyrosine, 4.8%; tryptophan, 1.8%; arginine, 10.2%; histidine, 6.9%; lysine, 2.8%; "amide" N, 1.2%; S, 3.58%; and total N, 17.8%. For detg. the acid-combining power of wool keratin by the quinhydrone electrode, the potential difference between the hydrogen electrode and the quinhydrone electrode at normal (760 mm. Hg) pressure of hydrogen was measured at temps. varying between 0° and 40°. The isoelec. point, estd. by extrapolation, is  $\text{pH}$  3.4, which agrees well with the value of Meunier and Rey. ## B—METHODS AND APPARATUS

STANLEY R. BENEDICT

**Iodometric determination of homogentisic acid in the urine.** HANS LIEB AND FRANZ LANYAR. *Univ. Graz. Z. physiol. Chem.* 181, 199–207(1929).—The method of Metz (*C. A.* 22, 4557), based on the oxidation of homogentisic acid to quinoneacetic acid in  $\text{NaHCO}_3$  or borax soln. by I and reversal of the reaction by acidifying, so that I consumption can be detd. by  $\text{Na}_2\text{S}_2\text{O}_3$  titration, is modified to overcome certain errors. It is important that the oxidation be performed in the presence of a considerable excess of pure  $\text{NaHCO}_3$  free from  $\text{Na}_2\text{CO}_3$ . If no other I-consuming substances are present, direct titration with I and starch indicator gives satisfactory results. In urine, however, such interfering substances are usually present and it is best to reverse the reaction by acidifying and titrate the liberated I. It is important here to use a considerable excess of acid, also an addn. of KI if only a small quantity of homogentisic acid is present, and to allow the mixt. to stand 15 mins. before titration. 0.05 N or even 0.01 N  $\text{Na}_2\text{S}_2\text{O}_3$  is recommended in place of 0.1 N. A correction of 0.2 cc. of 0.05 N  $\text{Na}_2\text{S}_2\text{O}_3$  per 10 cc. of urine is also added. The homogentisic acid content does not change in 24 hrs. if the urine sample remains slightly acid, but in alk. urine there is a distinct decrease on standing. The following technic is recommended: Dil. 10 cc. of the urine in a 0.5-l. flask with 90 cc.  $\text{H}_2\text{O}$ , add 2 cc. of 2% starch soln. and 1 g. pure  $\text{Na}_2\text{CO}_3$ -free  $\text{NaHCO}_3$ , and titrate immediately with 0.05 N I. As soon as the blue color appears add  $\text{NaHCO}_3$  from a spatula tip, shake and wait 0.5 min. If the blue color disappears add more I dropwise. Now add 100 cc. of dil.  $\text{H}_2\text{SO}_4$  (1:5) and 5 cc. of 4% KI, shake, let stand 15 mins. and titrate with 0.05 N  $\text{Na}_2\text{S}_2\text{O}_3$ . The no. of cc. of  $\text{Na}_2\text{S}_2\text{O}_3 + 0.20 \times 0.0042016 =$  the no. of g. of homogentisic acid in 10 cc. urine. The max. error is usually less than 0.5 mg. per 10 cc. urine. A. W. DOX

**An apparatus for the automatic and continuous determination of alveolar carbon dioxide.** REGELSBERGER. *Z. ges. expil Med.* 61, 747–56(1928). F. L. DUNN

**Acetone or acetoacetic acid?** HORKHIMER. *Pharm. Ztg.* 74, 499–500(1929).—In urine contg. AcMe it appears that as a rule only very small quantities of this substance are actually present, so that its recognition by the usual tests is practically impossible. That such samples do yield pos. tests for AcMe is due not to the latter, but rather to the presence of acetoacetic acid. The Lange ring test, that of Legal, as also the ethylenediamine reaction as modified by Kraft, recognize minute amts. of acetoacetic acid, and AcMe only when present in much greater quantity. The urine of healthy persons is believed to contain min. traces of acetoacetic acid. W. O. E.

**Method of estimating cysteine, cystine and their derivatives in tissues and biological fluids, and the application of the method.** YUZURU OKUDA AND KITARO KATAI. *J. Dept. Agr. Kyushu Imp. Univ.* 2, No. 5, 133–48(1929) (reprint); cf. *C. A.* 21, 3212. In this method, the proteins are first removed by sulfosalicylic acid pptn. and cysteine compds. are estd. in the filtrate by titration with standard iodate soln. in the presence of a fixed quantity of iodide. Cystine compds. after being reduced to cysteine compds. are run the same way. With normal blood serum and boiled milk either only traces or no cystine, cystine and their derivs. were obtained. On adding these amino acids to blood or milk, they were recovered quantitatively. The quantity of these amino acids in animal tissues decreases rapidly upon standing at room temp., but slowly in a frozen state or in strong acid soln. Roots and seeds contain cysteine or cystine compds. although some fruits were evidently free from cysteine compds. During the maturation of peas the quantity varies. RUSSEL C. EBB

**Two revised copper methods for blood-sugar determination.** OTTO FOLIN. Harvard Univ. *J. Biol. Chem.* 82, 83–93(1929); cf. *C. A.* 22, 2762.—A revised technic is described for the Folin and Folin-Wu methods for detg. blood sugar. Details are

given for the prepn. of the Cu reagent, the acid molybdate reagent, and the standard glucose solns. as well as the time of heating and the use of the colorimeter. A. G.

**The determination of true sugar in blood.** EDWARD S. WEST, FREDERICK H. SCHARLES and VERNON L. PETERSON. Wash. Univ., St. Louis. *J. Biol. Chem.* **82**, 137-53(1929).—Sugar analyses on blood filtrates obtained by pptn. with  $\text{Hg}(\text{NO}_3)_2$  and neutralization with  $\text{BaCO}_3$  to  $p_H$  6.3 gave values which agreed with those obtained by yeast fermentation. Normal, diabetic, uremic and diabetes-nephritic bloods behaved in this manner, but a case of cardiac hypertension with high N retention proved an exception. Some pig bloods also contained a non-fermentable reducing substance not removed by the  $\text{Hg}(\text{NO}_3)_2$ - $\text{BaCO}_3$  treatment. A  $\text{HgSO}_4$ - $\text{BaCO}_3$ -Zn technic is also described which is somewhat more accurate because the salt error is avoided. A. G.

**Difficulties and the overcoming of them in the determination of iodine in urine by means of palladous chloride after administration of iodine preparations.** HUGO BERNHARDT. Univ. Kiel. *Z. anal. Chem.* **76**, 351-4(1929).—To det. I in organic materials, *e. g.*, in the residues obtained by evap. urine, it is customary to heat with KOH and  $\text{Na}_2\text{O}_2$ , the latter being added to lower the m. p. and thus prevent volatilization of I. Such treatment, however, is likely to result in the formation of a little iodate so that the subsequent detn. of the  $\text{I}^-$  by means of  $\text{PdCl}_2$  often gives low results. This difficulty can be overcome by making the aq. ext. of the melt slightly acid with HCl and adding a little  $\text{Na}_2\text{SO}_3$ . Then, on heating, the  $\text{IO}_3^-$  will be reduced. By adding more HCl and boiling, the excess  $\text{SO}_3^{--}$  can be removed and then the  $\text{PdCl}_2$  pptn. will give all of the I. W. T. H.

**The estimation of the protein content of the urine by the Esbach process.** HANS SCHULTEN. *Klin. Wochschr.* **8**, 446-8(1929).—The drawbacks, advantages and instructions for avoiding gross errors are discussed in detail. A possible inaccuracy of 25% is to be expected under the very best conditions. MILTON HANKE

**An application of the method of Hagedorn and Jensen to the determination of larger quantities of reducing sugars.** CHARLES S. HANES. Botany School, Cambridge. *Biochem. J.* **23**, 99-106(1929).—The range of the Hagedorn and Jensen sugar method (*C. A.* **17**, 2721) has been extended to enable the estn. of 10 times the amt. of reducing sugar. BENJAMIN HARROW

**The preparation of lysine, histidine and arginine from hydrolyzed blood corpuscle paste by electrical transport.** GERALD J. COX, HARRIETTE KING AND CLARENCE P. BERG. Univ. of Ill. *J. Biol. Chem.* **81**, 755-64(1929).—The app. and procedure are modifications of the Foster and Schmidt method (*C. A.* **20**, 2311) for the prepn. of the basic amino acids by elec. transport. The yields of the pure final products from 1 kg. of blood corpuscle paste were as follows: *l*-histidine.HCl 51, *d*-arginine.HCl 21, *d*-lysine 2HCl 62, *l*-leucine 58, and *l*-tyrosine 22 g. A. P. LOTHROP

**Procedure of identification of stains of human blood by the method of deflection of complement using antisherp serum from guinea pig.** HECTOR DIACONO. *Bull. sci. pharmacol.* **36**, 72-7(1929).—The antihuman complex consists of human serum or a suspension of the blood stain and antihuman rabbit blood, inactivated at 56°. The hemolytic system was antisherp blood from guinea pig and red corpuscles from sheep. The hemolytic serum is titrated first, 0.02-0.008 cc. being used. In the test, the human serum is dild. from  $1/_{500}$  to  $1/_{2000}$ . It was found that a stain, dild. to  $1/_{2000}$  with saline, can be identified with reliability. Controls with blood from sheep, hog, beef, etc., are made. A. E. MEYER

**Determination of uric acid alone.** L. TIXIER. *Bull. sci. pharmacol.* **36**, 77-9(1929).—The method depends upon the pptn. of the uric acid by an ammoniacal  $\text{CuSO}_4$  soln., treatment of the filtrate with excess KCN to convert the excess Cu  $(\text{NH}_3)_4^{++}$  to  $[\text{Cu}(\text{CN})_4]^{--}$  and titration of the excess  $(\text{CN})^-$  with  $\text{Ag}^+$  by the Liebig method. Treat 50 cc. of urine with a soln. prepd. by dissolving 4 g. of blue vitriol in 500 cc. of water, and dilg. to 1 l. with concd.  $\text{NH}_4\text{OH}$ . Filter after standing 1 hr., wash with 5 cc. of 10%  $\text{NH}_3$  soln. and add to the filtrate 5 cc. of the following soln.: 20 g. KCN, 10 cc. concd.  $\text{NH}_4\text{OH}$ , 60 g. of KI and water to make 1 l. Titrate with 0.1 N  $\text{AgNO}_3$  soln. of which 1 cc. is equiv. to 0.01 g. of uric acid. A. E. MEYER

**The preparation of a solution isotonic with serum, for use in determining the relative osmotic pressure of the cations in serum and the volume index of the blood corpuscles in cutaneous blood.** INGVAR CHRISTENSEN AND ERIK J. WARBURG. *Acta med. Scand.* **70**, 286-302(1929).—An aq. soln. contg. per l. 11.300 g.  $\text{Na}_2\text{C}_2\text{O}_4$ , 0.315 g.  $\text{KH}_2\text{PO}_4$  and 1.265 g.  $\text{Na}_2\text{HPO}_4$  is isotonic with serum. With this fluid the relative osmotic pressure of the serum cations can be measured with an error of 0.86% in duplicates, and in 23 detns. the max. deviation from the mean value of the cation concn. was 2.4-3.0%. The erythrocytes shrank 4% if suspended in a large vol. of non-buffered

1.3%  $\text{Na}_2\text{C}_2\text{O}_4$  soln. and if not protected against  $\text{CO}_2$  loss. No variation in the serum cation concn. through the day was found nor was any variation observed after a sweating bath.

S. MORGULIS

The ammonia formation in muscle and its relation to changes in function and state.

VI. Connection between ammonia formation and the transformation of adenine nucleotide to inosinic acid. J. K. PARNAS. Univ. Lemberg. *Biochem. Z.* 206, 16-38 (1929).—Methods are described for the detn. of aminopurines and oxypurines as well as of aminopurine and oxypurine nucleotides in small quantities of muscle. The muscle is quickly rubbed up with sand and 1%  $\text{H}_2\text{SO}_4$ , the resulting pulp is dild. to 25 cc. It is then autoclaved 4 hrs. at  $115^\circ$ , made slightly alk. and again slightly acidified with AcOH and filtered hot. The purine is detd. in the filtrate by the method of Krüger and Schmidt. A procedure is described for sepg. 3 fractions: total purine N, adenine N and hypoxanthine N. In fresh muscle (frog) prepd. with every precaution to avoid traumatic  $\text{NH}_3$  formation the purine bases are present almost entirely as free nucleotides; only 4% of the aminopurine N can be a component of true nucleic acid, while free amino purine bases and nucleotides are altogether absent. In the fresh muscles of winter frogs 82% of the purine N is adenine and 18% hypoxanthine N; in muscles of summer frogs the corresponding quantities are 89 and 11%. The guanine makes up only about 1.4% of the total purine N. Mech. destruction of the muscle which causes the formation of  $\text{NH}_3$  brings about the transformation of most of the adenine nucleotide to inosinic acid. A few min. after the muscle is rubbed up there is only 23% adenine and 77% hypoxanthine N of the total purine. The deamination of adenine nucleotides in winter is equiv. to the traumatic  $\text{NH}_3$  formation, but during the summer it does not seem that this is the only source of  $\text{NH}_3$ . When frog muscle is fatigued by stimulation of the nerve under anaerobic conditions the conversion of adenine to hypoxanthine is equiv. to the  $\text{NH}_3$  formation, but when the fatigue is produced under a plentiful  $\text{O}_2$  supply the  $\text{NH}_3$  formation exceeds the conversion of adenine to hypoxanthine. This is attributed to a resynthesis of adenine nucleotide from inosinic acid. S. M.

Studies on iodine metabolism. II. The iodine content of normal and pathologically altered thyroids. GULBRAND LUNDE, KARL CLOSS AND K. WÜLFERT. Univ. Oslo. *Biochem. Z.* 206, 248-60 (1929); cf. *C. A.* 22, 2956.—A relatively large piece of thyroid under investigation is digested on the water bath with at least  $\frac{1}{2}$  its wt. of KOH and a little  $\text{H}_2\text{O}$ , subsequently also EtOH, until a homogeneous soln. results, from which an aliquot is taken for analysis. This is ashed in an iron crucible with a little  $\text{K}_2\text{CO}_3$ , the ash repeatedly extd. with alc. and the exts. are evapd. to dryness with a few drops of satd.  $\text{K}_2\text{CO}_3$  in a gold dish. The residue is carefully heated to a glow and again extd. with alc. The exts. (without the addn. of  $\text{K}_2\text{CO}_3$ ) are again evapd. in a gold-platinum dish, carefully heated over the flame, transferred quantitatively to a 50 cc. Erlenmeyer flask and titrated. Normal, Norwegian thyroids of an av. wt. of 24.66 g. contain 9.86 mg.  $\text{I}_2$ . The relative content is 0.043% of the fresh gland or 0.1553% of the dry substance. The  $\text{I}_2$  content of atoxic goiters is very variable, but greater than is stated in the literature. In secondary hyperthyreosis very high  $\text{I}_2$  values were found in colloid goiters (toxic adenomas), even more than in normal glands. In primary hyperthyreosis (Basedow) the goiter is poor both in colloid and in  $\text{I}_2$ , but on treatment with  $\text{I}_2$  the goiter becomes colloid- and  $\text{I}_2$ -rich.

S. MORGULIS

A simplification of the freezing-point determination on small quantities of biological fluids. E. FROMM AND TH. LEIPERT. Univ. Wien. *Biochem. Z.* 206, 314-8 (1929).—The app. consists of a small Dewar flask into which a centrifuge tube is fitted. The latter is closed with a stopper and serves as the cooler. It is filled with a mixt. of a const. f. p. This is prepd. by dissolving 6.54 g.  $\text{K}_2\text{SO}_4$  in 93.46 g.  $\text{H}_2\text{O}$ , which has a const. f. p. of  $-1.55^\circ$ . This mixt. can be kept indefinitely in a frozen condition but before needed the cooler is filled with this and by undercooling and const. stirring it is converted into a mass of fine crystals. Through the stopper which closes the cooler are inserted directly into this crystal mass a thermometer and a cryoscope tube (plain test tube). An ordinary N-filled thermometer is used to det. the lowering of the f. p. which is calibrated from  $+1$  to  $-3^\circ$  over a distance of 12 cm. This allows accurate reading to  $0.005^\circ$ . So long as a freezing bath of const. temp. is employed, the f. p. of pure water detd. by this inexpensive thermometer undergoes no changes and need not be redetd.

S. MORGULIS

Determination of protein fractions of blood by the gravimetric and nephelometric method. ST. RUSZNYÁK AND J. ERDÖS. Kgl. Univ., Budapest. *Biochem. Z.* 206, 482-4 (1929).—The nephelometric detn. of the various protein fractions of blood gives results very closely parallel to the gravimetric detn.

S. MORGULIS

Studies on the methylene blue method for the investigation of biological dehydro-

genation. I. Measurements of  $p_H$  with the quinhydrone electrode at  $37^\circ$  in succin-dehydrogenase solutions in the presence of methylene blue. JÖRGEN LEHMANN. Univ. Lund. *Skand. Arch. Physiol.* 55, 307-15(1929).—The  $p_H$  was measured up to  $p_H = 8.0$  and at  $37^\circ$  with an accuracy of 0.01  $p_H$  with the quinhydrone electrode in the presence of methylene blue-leucomethylene blue, and of succinic acid-fumaric acid. In the presence of methylene blue generally const. potentials were obtained where, without the dye, usually a drifting potential was found. Furthermore, with methylene blue the measurable range extended further on the alk. side. The  $p_H$  detns. were unaffected by concn. of the methylene blue.

S. MORGULIS

Substances preventing biological reactions in the detection of blood and of copper. G. CARPENTIER. *Union pharm.* (May, 1928) 193-4; *Chimie et industrie* 21, 261.—In addn. to org. compds. (polyphenolic complexes and aldehydes) certain inorg. compds. can prevent the biol. reactions for the detection of blood and of Cu. They are compds. having a high affinity for O and which absorb the available O of  $H_2O_2$  before the latter can be fixed by the blood or the Cu (e. g., sulfites, hydrosulfites and hyposulfites). C has observed that these compds., and particularly hyposulfites, interfere with the guaiacol (Weber) reaction, pyramidone (Escaich) reaction, and benzidine reaction. When only a small quantity of hydrosulfite is present, excess of  $H_2O_2$  and reagent (e. g., in Meyer's phthalein reaction) can be added. The question as to whether the above-mentioned salts also react with blood would require investigation. A. P.-C.

A new method for the ascertaining of death. STEFANO MARRADI FABRONI. Univ. Adriatica "Benito Mussolini," Bari. *Arch. farmacol. sper.* 46, 177-88(1929).—In expts. with guinea pigs and rabbits F. worked out the following method for ascertaining the death. Immediately before the test a satd. soln. of  $Na_2S_2O_4$  was added to an aq. 2% soln. of methylene blue, until complete decolorization occurred. An excess of  $Na_2S_2O_4$  has to be avoided. The mixt. was filtered and immediately after the animal was killed, 1 cc. was injected under a shaved area of the skin. The syringe used has to be perfectly dry. While in the live animal the skin in the vicinity of the place of injection assumed an intense bluish color, which does not change its hue for several hrs., no color appeared in the dead animal. In a few cases a very faint localized color was observed. These results were verified with human cadavers. The method is said to be rapid, simple and reliable. Numerous references are given. G. SCHWOCH

Hg-vapor lamp suitable for therapeutic uses, etc. (Brit. pat. 298,903) 4.

## C—BACTERIOLOGY

CHARLES B. MORREY

*Vibrio agarliquefaciens* Gray. J. B. VAN DER LEK. *Nederland Tijdschr. Hyg. Microbiol. Serol.* 3, 276-80(1929).—This bacterium isolated by Leeftang is similar to the *Microspira agarliquefaciens* of Gray and Chalmers, but it attacks agar much more energetically. Cellulose is also attacked, and if a nitrate is used as source of N, the action is much faster than with an  $NH_4$  salt. A good growth was obtained with starch and glucose, but not with xylose and glycerol. In the attack on agar a little acid is formed, and the liquefied agar does not show reduction with Fehling soln., and no coloration with I.

J. C. JURRIJENS

Tryptophan-peptone solution prepared from casein as medium for fecal coli bacteria at  $45-46^\circ$ . T. FOLPMERS. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* 3, 281-4 (1929).—A description of the method is given in detail. After 6 hrs. it shows an indole reaction. F. has used this soln. daily for over a year in conjunction with the Eykman test for river water, while for drinking water the MacConkey test is added with lactose as sugar. Neither *aerogenes* nor *cloacae* influences the reaction. It is advisable to apply the above-mentioned 3 tests at the same time. Positive results indicate the amt. of fecal coli in the sample. Sugars and also mannitol added in low concn. to the tryptophan soln. prevent the formation of indole.

J. C. JURRIJENS

Researches in vitro on the nature of the antiviral of Besredka. H. ALDERSHOF. The Govt. Serol. Inst. at Utrecht. *Nederland. Tijdschr. Hyg. Microbiol. Serol.* 3, 285-97(1929).—The factor, in the antiviral of Besredka, inhibiting growth, is non-specific. For the production of this factor bacterial growth is not necessary, as it is produced by filtration through Chamberland or EK filters even from uninoculated bouillon. The strength of the factor is proportional to the amt. of filtration. The factor obtained from inoculated and filtered bouillon does not differ from the one obtained from uninoculated and filtered bouillon; both are thermostable. The filtration effect is not due to the removal from the bouillon of colloidal substances, nor of fats, sugars or salts, but probably to a colloidal-chem. change of part of the albumin, causing

these bacteria not only to become immune from attack, but also to be inhibited in their growth.

J. C. JURRËNS

**The nitrogen metabolism of *Bacillus mycoides*. I. Influence of the nutritive medium on the growth and nitrogen metabolism of *B. mycoides*.** HELENE GLINKA-CHERNORUTSKII. Med. Inst., Leningrad. *Biochem. Z.* 206, 301-7(1929).—*B. mycoides* cultures on 1% peptone decomp. protein quickly and produce appreciable quantities of  $\text{NH}_3$ . The addn. of 1% glucose has a protein-sparing effect. The formation of amino acids and  $\text{NH}_3$  does not change the peptone fraction precipitable through  $(\text{NH}_4)_2\text{SO}_4$ . The biuret reaction does not disappear even after many inoculations of the same medium. Media consisting only of monoamino acids inhibit the development and growth of *B. mycoides*. **II. Proteolytic enzymes.** *Ibid* 206, 308-13(1929).—The proteolytic enzymes of *B. mycoides* are principally intracellular and resemble the trypsinases in their action. The addn. of 1% glucose to the nutritive medium has no effect on the development of the enzymes, nor does this diminish their activity. The protein-sparing action of the glucose is therefore due to the fact that glucose as a highly potent energy source for bacteria makes the utilization of much protein superfluous.

S. MORGULIS

**Oxidation-reduction equilibria in biological systems. II. Potentials of aerobic cultures of *B. typhosus*.** CALVIN B. COULTER AND MOSES L. ISAACS. Columbia Univ. *J. Exptl. Med.* 49, 711-25(1929); *C. A.* 22, 4550.—The reduction potentials of *B. typhosus* in culture in bouillon which is given access to atm. O show a neg. drift that attains the values found in sterile bouillon when deaerated with N:  $E_h$  —0.085 to —0.095 v. at  $p_{\text{H}}$  7.6. The potential reaches that level after 6 to 8 hrs. incubation, and is maintained at this point for several hrs. A slow decline to more neg. values is then observed and continues for at least 48 hrs., when a potential of —0.145 v. may be attained. The bacteria influence the potentials in the first period of their growth by exhaustion of O from the culture, thus permitting the characteristic potential of the culture medium to become manifest and do not contribute the substances responsible for the observed potentials. The decline in potential to values more neg. than those of the culture medium occurs during the time that the rate of dyeing of the bacteria approaches and exceeds the rate of multiplication. Cultures in 0.5% dextrose medium show a somewhat more neg. potential after 18 hrs. growth than cultures in medium without dextrose. This may be due to the more rapid "turn-over" of the bacteria and the liberation of larger amts. of reductive material from soln. of larger nos. of bacteria. The potential of cultures through which O is passed continuously does not show a neg. drift at any time. This indicates that reductive substances of bacterial origin at least in the typhoid bacillus do not influence the electrode potentials in the presence of O.

C. J. WEST

**"Soluble specific substance" derived from gum arabic.** MICHAEL HEIDELBERGER, OSWALD T. AVERY AND WALTHER F. GOEBEL. Rockefeller Inst. Med. Research. *J. Exptl. Med.* 49, 847-57(1929).—By partial acid hydrolysis a sp. carbohydrate may be isolated from gum arabic. This carbohydrate is comparable in its pptg. activity for Type II (and Type III) antipneumococcus serum with the bacterial sol. sp. substances themselves. On hydrolysis this fraction yields galactose and 2 or more complex sugar acids, 1 of which appears to be a disaccharide acid comparable with those isolated from the sp. polysaccharides of the Type III pneumococcus and the Type A Friedländer bacillus. The significance of these findings is discussed.

## D—BOTANY

THOMAS G. PHILLIPS

**The photochemical yield of chlorophyllic assimilation with complex and intermittent light.** M. PADOA AND NERINA VITA. *Gazz. chim. ital.* 58, 647-54(1928); cf. *C. A.* 23, 1058.—In studying the influence of colored and of white light on *Elodea canadensis* immersed in water satd. with  $\text{CO}_2$ , the quantity of O evolved was used as a measure of assimilation, correction not being made, however, for the O consumed in respiration which proceeds at the same time. The sum of the components of white light gave far higher yields than did the integral white light, the av. additive yield of yellow, green and red light being 21.8 times that of the integral white light, showing as in earlier expts. that, in assimilations reactions, photochem. interference exists in white light. In comparative expts. with continuous and pulsating white light, as the frequency of the pulsations increased, there were several points of max. yields, between which were regions of smaller yields, each with a corresponding min. These max. yields were 1.5-2.7 times those of continuous light, the highest occurring at 650 pulsations per sec. With con-

tinuous and pulsating red light, there were also maxima and minima as the frequency of the pulsations increased, but the relative changes with respect to the yields with continuous red light were far less than with continuous and pulsating white light.

C. C. DAVIS

**Physiological function of magnesium in plants.** E. CANALS. *Bull. soc. chim. biol.* 10, 1260-1276 (1928).—The Mg and Ca contents of the ash from various parts of a large no. of plants show wide variations (Ca 2.2-35.5, Mg 0.8-5.7%; Ca:Mg 0.81-32.2). Except in herbaceous plants, the leaves contain more Mg than the stems and the amt. of Ca generally increases with the age of the tissue. Dialysis of the juices of fungi and potato shows that a large proportion of the Mg and Ca exists in an inorg. form, probably as phosphate.

B. C. A.

**Carbon dioxide assimilation of the sugar beet.** H. LUNDEGÅRDH. *Flora* 21, 273-300 (1927).—An app. is described for measuring C assimilation of leaves with varying partial pressures of CO<sub>2</sub>. The following results are reported for sugar beet leaves:

Light intensity	CO <sub>2</sub> in air used	Optimum CO <sub>2</sub> assimilation at:
1. Full sunlight	0.03% by vol.	19°
2. 1/2 full sunlight	0.03% by vol.	11°
3. Full sunlight	0.84% by vol.	35°
4. 1/2 full sunlight	0.84% by vol.	20°

Twelve tables of results are included. Attention is called to the fact that in the artificial addn. of CO<sub>2</sub> to air, the most significant increases in C assimilation take place at relatively high temps. The differing optima for hardy and semi-tropical plants are discussed from the standpoint of plant geography. Thus, as may be seen from the following table, the potato is best adapted to a high assimilation temp.; the sugar beet may succeed over a wide range; while the anemone is an outstanding cold weather plant.

	Mg. CO <sub>2</sub> assimilated per 50 sq. cm. leaf area in 1 hr. from air contg. 0.57 mg. CO <sub>2</sub> per l.				
	0°	10°	20°	30°	40°
Potato	0.9	4.2	9.5	4.6	
Tomato	3.3	6.0	8.4	3.9	
Sugar beet	3.0	6.0	8.5	7.0	3.8
Anemone nemorosa	2.8	5.5	5.2	3.2	

R. C. BURRELL

**Studies on top yeast.** HANS V. EULER AND HARALD NILSSON. *Univ. Stockholm. Z. physiol. Chem.* 181, 281-90 (1929).—Top yeast R was suspended in 3% sucrose, the soln satd. with H<sub>2</sub>S and left 24 hrs. at room temp. The yeast, which had now become black-gray and developed a garlic odor, was then centrifuged. Fermentation tests showed that this treated yeast was about 1/4 as active as the untreated yeast, both in terms of CO<sub>2</sub> production and O consumption. In the dried state, however, the ratio of O consumption was only 1:14. It is probable that the drying of the H<sub>2</sub>S-yeast converted a considerable portion of the Fe catalysts into FeS, thereby causing inactivation. Ordinarily, top yeasts differ from bottom yeasts in the difficulty of removing cozymase from their dried preps. by washing. After the H<sub>2</sub>S treatment, however, the cozymase is easily washed out from the dried prepn. of top yeast.

**Plasmolysis produced by concentrated sugar and salt solutions.** B. BRILLIANT. *Compt. rend. acad. sci. U. R. S. S.* 1927, 155-60; *Physiol Abstracts* 13, 332.—Unilateral plasmolysis results when leaves of *Catherinea undulata* or *Mnium spp.* are placed in a 1 to 1.5 M soln. of maltose. In concd. glucose unilateral plasmolysis is observed only in those cells nearer the midrib than the margin of the leaf. The form of plasmolysis in salt solns. varies with the salt and its concn.

H. L. D.

**The effect of some growth conditions on chemical composition and metabolism in the sugar-cane leaf.** R. R. FOLLETT-SMITH. *Minutes of Proc. Froghopper Investigation Committee*, 17 pp. (1928); *Physiol Abstracts* 13, 331.—Analyses of the leaves of sugar canes growing in alk. and acid regions are given. Diurnal variations in ash and sugars of the 2 kinds of leaves are recorded.

H. L. D.

**The determination of manganese in vegetable ashes.** MAURICE GARNIER. *Bull. sci. pharmacol.* 36, 140-6 (1929).—The method of Gabriel Bertrand is used. A table gives the analytical findings of Mn in 45 different plants. The soil, where the plant has grown, has no influence on its Mn content.

A. E. MEYER

**Note on coumarin plants.** C. WIMMER. *Ber. deut. botan. Ges.* 47, 119-20 (1929); cf. C. A. 23, 1155.—A discussion of the occurrence of coumarin among the Compositae.

L. P. MILLER

Conditions for the germination of the spores of the fungus *Dasyscypha wilkoniai*. N. MALYCHEV. *Rev. gén. botan.* 41, 185-90(1929).—These spores germinate in an agar medium if ext. of fresh larch branches is added or if it contains 13-35% glycerol or 7-13% sucrose. The ext. of dried larch cannot be used. Germination takes place in the dark in 7-30 days. L. P. MILLER

The production of fumaric acid in sugar cultures of *Mucor stolonifer* (*Rhizopus nigricans*) and its relation to pyruvic acid. VL. S. BUTKEVICH AND M. V. FEDOROV. Timirjazeff-Forschungs-inst., Moscow. *Biochem. Z.* 206, 440-56(1929).—In sugar cultures of *Mucor stolonifer* under the condition of a relative N lack and in the presence of  $\text{CaCO}_3$  there is a considerable accumulation of fumaric acid, which may amount to 30-40% of the total consumed sugar. If the sugar used up in the production of alc., etc., is taken into consideration the estd. yield of fumaric acid equals nearer 50% of the sugar decompd. In the absence of  $\text{CaCO}_3$  the accumulation of fumaric acid is very much less, and its max. content does not exceed 0.5%. Evidently the acidity limits the formation of fumaric acid. An increased acidity also diminishes the sugar consumption by the molds, but this can be enhanced at once by the addn. of  $\text{CaCO}_3$ . Besides the fumaric acid, succinic acid is found, nearly 10% of the total acid production. The molds develop very well in a medium of proper acidity where fumaric acid, as the sole source of C, is present together with  $\text{NH}_3$ , which indicates that the fumaric acid is utilized further in the metabolism of the molds, and is merely an intermediate step in the sugar metabolism. S. MORGULIS

Starch formation and its relation to acid production by the mold *Penicillium* Link. T. CHRZASZCZ AND D. TIUKOW. Inst. f. landwirtschaftl. Technologie, Poznań. *Biochem. Z.*, 207, 39-52(1929); cf. *C. A.* 23, 1927.—Production of starch-like substances by *Penicillium* is an entirely normal process, which, however, requires special conditions in some molds. Among these molds 2 groups may be distinguished: the starch producers and the acid producers; the starch-like substances and the org. acids play the part of nutritive reserves. The former group produces less org. acid than the latter. It is suggested that the starch-forming organisms in an evolutionary sense are the older, whereas the formation of starch in those molds which ordinarily produce some other substances is to be regarded as an atavistic reversion. The starch is formed in varying quantities and generally in layers. S. MORGULIS

The color reactions of lignin. FRAN PODBREZNIK. Institut du Pin, Bordeaux, France. *Pulp Paper Mag. Can.* 27, 229-33, 246-8(1929).—See *C. A.* 23, 863.

A. PAPINEAU-COUTURE  
The death wave in *Nitella*. II. Application of unlike solutions. W. J. V. OSTERHOUT AND E. S. HARRIS. Rockefeller Inst. *J. Gen. Physiol.* 12, 355-61(1929); cf. *C. A.* 22, 4580.—The hypothesis that protoplasm is composed of an outer and an inner non-aq. layer between which is an aq. layer enables one to predict the bioelec. behavior of a cell under a variety of conditions. In this paper prediction of behavior is made when a death wave in the cell of *Nitella* passes through different points in contact with unlike solns. of KCl. C. H. RICHARDSON

The relation between the production of lactic acid and the growth of yeast. E. AUBEL. *Compt. rend.* 188, 578-80(1929).—Referring to a former study (*C. A.* 20, 2869), A. attempts to solve 2 problems that have remained unexplained in the earlier expts. The 1st problem concerns the inconsistency of the results obtained with the growth of yeast on lactic acid. The presence or absence of nitrates had no influence on the outcome of the results. A. is now convinced that the yeast itself contains a substance necessary for its growth. Possibly this is glycogen. Yeast does not grow on lactic acid in the absence of air even in the presence of nitrates. As to the 2nd problem, the hypothesis that nitrates play a role in the synthesis of glucose at the expense of lactic acid was investigated. It was observed that under anaerobic conditions the presence of nitrates did not alter to a noteworthy degree the quantities of lactic acid and alc. produced by the yeast with glucose as the substrate. There was no relation between the amt. of lactic acid and the no. of yeast cells formed. Conclusion: The energy required for the growth of yeast is not furnished by the cleavage of glucose into lactic acid. G. SCHWOCH

Changes in the cells and tissues of root tips induced by the absence of calcium. HELEN SOROKIN AND ANNA L. SOMMER. Univ. of Minn. *Am. J. Botany* 16, 23-39(1929).—Plants of *Pisum sativum* grown in culture soln. without Ca usually die within 2 or 3 weeks. The first visible effect of the absence of Ca may be detected in a decrease in the amt. of cytoplasm and in the appearance of large vacuoles in the meristematic cells. In the absence of Mg, microorganisms accelerating the disintegration of the tissues are excluded and there is better development of the pathological tissue, which undergoes a

slower solution than does tissue in which the presence of microorganisms has been observed. The cell wall was never found to be underdeveloped or disintegrating in the apical portion of the roots nor in the region of elongation of plants deprived of Ca. It appears that the absence of Ca does not have a direct effect on the disintegration of tissues due to the sepn. of the cells, because of the absence of Ca pectate, as held by some previous writers. The effect of the absence of Ca is on the meristematic cells, either because it is a necessary chemical constituent of the protoplast and therefore in its absence the mitotic divisions are disturbed, or because its absence so affects the physical condition of the colloidal system that normal mitoses are not possible. J. J. SKINNER

A physicochemical study of the leaves of three medicinal plants in relation to evergreenness. GEORGE B. RIGG AND RUSSELL A. CAIN. *Am. J. Botany* 16, 40-57 (1929).—Metabolic processes seem to play more or less important roles in the plant which enable it to withstand extreme cold. Factors which tend to hold the water in the cell will prevent freezing. These factors may be in the form of decreased moisture content, anatomical structure, increased amt. of hydrophilic colloids, acidity changes, increased salt content, or accumulation of sugars. The increased oil or fat content may also serve as a protecting factor. The moisture content varies inversely as the degree of hardness. There is a gradual increase in the amt. of total sugars present in the leaf of evergreens during the winter. The starch and pentosans decrease during the winter. The amt. of press-juice varies inversely with the hardness of the leaves. A close relationship exists between the amt. of pentosans and press-juice obtained in the *Arctostaphylos uva-ursi* and *Digitalis purpurea*, though the opposite was true with *Atropa belladonna*. No relationship was found between the amt. of starch and press-juice in the leaves. The metabolic conditions present in the 2 evergreen species and not present in the non-evergreen are similar to those present in hardened and not present in non-hardened plants. J. J. SKINNER

The influence of boron on the chemical composition and growth of the tomato plant. EARL S. JOHNSTON AND W. H. DORE. Univ. of Maryland and Univ. of California. *Plant Physiology* 4, 31-62(1929); see C. A. 22, 1994. WALTER THOMAS

Some critical comments on the methods employed in the expression of leaf saps. BERNARD S. MEYER. Ohio State Univ. *Plant Physiology* 4, 103-12(1929).—Methods (C. A. 9, 475; 10, 2904; 21, 3651) which have been used in the treatment of leaves for studies on leaf sap are summarized and evaluated. A field method of freezing leaf samples in solid CO<sub>2</sub> is described. Details are given for the construction of a press which embodies certain principles in design not hitherto adopted. Papers reporting the results of detns. of the physico-chemical properties of expressed plant saps should include the following information: water content of the tissue, exact treatment and method of handling the tissue, magnitude of the pressure employed, and the vol. of sap expressed as a percentage of the fresh wt. or water content of the tissue. Only with such information available can the reader reconstruct for himself a reasonably accurate picture of the exact effects of the treatment and pressure upon the tissue and only if such information be supplied can the detns. be duplicated. WALTER THOMAS

Origin and evolution of mannitol in plants. F. OBATON. *Compt. rend.* 188, 77-9(1929).—When *Sterigmatocystis nigra* is grown in a medium contg. NH<sub>4</sub>NO<sub>3</sub> and sucrose, mannitol is produced continuously up to about 48 hrs. At this time fructification begins, and the mannitol diminishes. Under other circumstances it diminishes when the available C becomes low. Its formation seems to be independent of that of trehalose. In the celery (*Apium graveolens*) mannitol is found in leaves, stems and roots, and is produced only during high chlorophyll activity. J. J. WILLAMAN

Proteolysis and proteogenesis in ligneous plants at the beginning of vegetative activity. R. COMBES AND M. PINNEY. *Compt. rend.* 188, 79-81(1929).—Trichloroacetic acid being used to distinguish between protein and non-protein N, the roots, twigs and leaves of beech were examd. monthly from December through July. In the roots and twigs, proteolysis begins in February in anticipation of the opening of the buds in March, and continues to April. Proteogenesis then begins in all 3 organs, and continues through June. During July proteolysis again obtains. J. J. WILLAMAN

Comparative plant chemistry. XXI. Milk-bearing plants. 4. J. ZELLNER. *Monatsh.* 50, 211-5(1928); cf. C. A. 22, 446.—From *Campanula trachelium* there was isolated a glucoside, (C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>)<sub>n</sub>, named "campanulin" by the authors. It is the main constituent of the juice of this plant. From *Lactarius rufus* there was isolated lactic acid, C<sub>12</sub>H<sub>22</sub>O<sub>11</sub>, mannitol and glucose. J. J. WILLAMAN

Chemistry of the higher fungi. XIX. *Polyporus pinicola* Fr. E. HARTMANN AND J. ZELLNER. *Monatsh.* 50, 193-200(1928).—The following substances were isolated: cerebrine; trehalose; ergosterol; fungisterol; several unidentified sterols;

AcOH, butyric acid, glycerol and choline in the sapond. fat; a resin acid. These results definitely differentiate this fungus from *Polyporus officinalis*. XX. *Omphalia campanella*, *Marasmius scorodonius*, *Boletus canipes* and *Calocera viscosa*. N. FRÖSCHL AND J. ZELLNER. *Ibid* 201-10.—From the first-named fungus were isolated mannitol, glucose, choline and a phlobaphene. From the second, a new substance, marasmin (possibly identical with betonicin),  $C_7H_{11}NO_3$ , which browns at  $195^\circ$  and m. with decompn. at  $242^\circ$ ; choline; glucose; while mannitol and trehalose were absent. From the third, mannitol and glucosan were isolated. From the fourth, trehalose, ergosterol, fungisterol, palmitic, stearic and isovaleric acids, calocerol, a new substance of sterol nature,  $C_{22}H_{38}O_8$ , and glucose and choline were isolated. J. J. WILLAMAN

The speed of absorption of ions in plants. M. v. WRANGELL. *Z. physik. Chem.* Abt. A, 139, 351-67(1928).—Maize seedlings were used to det. the rate of absorption of  $PO_4$  ions and of  $NH_4$  ions from very dil. solns., less than 0.1 mg. per l. The former is absorbed rather slowly, but the latter very rapidly. Within short exptl. periods of time, the absorption of either was independent of light and of other nutrient salts, but was much influenced by temp. and the reaction of the medium. It seemed to follow the law of mass action fairly well, but still better the adsorption isotherm. J. J. W.

Photosynthesis of naturally occurring compounds. IV. The temperature coefficient of the photosynthesis of carbohydrates from carbonic acid. E. C. C. BALY AND N. R. HOOD. Liverpool Univ. *Proc. Roy. Soc. (London)* A122, 393-8(1929); cf. C. A. 21, 3649.—Ni carbonate free from alkali was prepd. by electrolysis of carbonated cond. water with Ni electrodes. The dry carbonate was activated by white light. It was then suspended in carbonated water under const. conditions of illumination by white light, and the amt. of carbohydrates produced at  $5^\circ$  to  $41^\circ$  was detd. The yields increased linearly up to  $31^\circ$ , after which there was a rapid decline. The temp. coeffs. for each  $10^\circ$  were remarkably close to those which have been found for photosynthesis in plants, and the yield-temp. curves were very similar in the 2 cases. The authors offer these results as further support to the view that the complete photoactivation of  $CO_2$  is achieved in 2 stages: partial activation by adsorption on the surface of the catalyst, and further activation by the action of visible light on the absorbed surface. J. J. WILLAMAN

The relation of plants to the mercury disinfection of the seeds. WOLFGANG HEUBNER. *Pharmakol. Inst., Göttingen. Z. Physik. Chem.* Abt. A, 139, 198-210(1928).—Two org. Hg prepn., Germisan and Uspulun, were used to disinfect wheat seeds, and the rate of germination and Hg content of the seedlings noted. No stimulative action in germination was found. Hg was found in the sprouts, roots and cotyledons to the extent of 0.66, 0.74 and 0.75 mg. Hg per 100 g., indicating that the Hg was absorbed into the living tissue in appreciable amts. J. J. WILLAMAN

The electromotive force of alkaline and of acid plant tissues. KURT STERN. Frankfurt a. M. *Z. Physik. Chem.* Abt. A, 139, 224-34(1928).—The petals of the cornflower were taken as an alk. tissue, the petals of a red rose, as an acid tissue. In both cases either mech. irritation (pressure between thumb and finger) or chem. irritation (KCl solns.) gave rise to an e. m. f. of 0.1 v. The affected side was electronegative to the normal side. The significance of these findings is discussed in relation to muscle excitation. J. J. WILLAMAN

## E—NUTRITION

PHILIP B. HAWK

The calcium and phosphorus concentration in the intestinal contents of rats in relation to rickets. ANGELIA M. COURTNEY, F. F. TISDALL AND ALAN BROWN. *Can. Med. Assoc. J.* 19, 559-62(1928).—Normal rats have an acid reaction at the beginning of the small intestine and the reaction becomes more alk. throughout the tract. Rats on rachitogenic diet, whether exposed to the sun or not, have a more alk. reaction at the beginning of the small intestine than the normal rats. With rats not exposed to sunshine the reaction begins at once to increase in alk. With rats exposed to sunshine the contents remain at practically the same reaction throughout the length of the

intestine. The total Ca content of the cecum of rats fed on McCollum's rachitogenic diet and kept inside was much higher than that of rats fed the same diet and exposed to sunshine. Ca bound with P was practically the same in the cecum of both groups; hence the difference in Ca content is due to Ca not bound with P. No essential difference was found in the P concn. in the large intestines of the 2 groups. Ca absorption or excretion in relation to rickets may not be so intimately assocd. with P as is generally supposed.

A. T. CAMERON

The relation of the altitude of the sun to its antirachitic effect. F. F. TISDALL AND ALAN BROWN. *Can. Med. Assoc. J.* 20, 253-9(1929).—A marked increase occurs in the antirachitic effect of sunshine when the sun reaches an altitude of 35° or more. Study of the geographical distribution of rickets shows that rickets is uncommon, or exists chiefly in a mild form, in those places where the min. seasonal altitude of the sun is not below 35°. Conversely severe rickets is chiefly encountered in those cities where the altitude of the sun is below 35° for some months of the year. The period of the year during which rickets will probably develop can be calcd. for any city in the world. The duration of this period may be altered by the prevention of exposure of patients to highly effective sunshine through inclement spring weather or other factors.

A. T. CAMERON

Some organ alterations by large doses of vigantol in the rat. FR. HOLTZ AND TH. V. BRAND. Univ. Göttingen and Univ. Erlangen. *Z. physiol. Chem.* 181, 227-33(1929).—"Vigantol," a vitamin-D prepn. supplied by Merck, was dissolved in olive oil and fed to rats in doses as high as 100,000 times the therapeutic dose. The animals receiving this high dosage (10 mg. per day) made much smaller gains in wt. than the control animals or those receiving 0.1 mg. Histological examn. of the organs showed calcification in the kidney, lung and occasionally aorta, but not in the heart, liver, spleen or suprarenals. These alterations may possibly be due not so much to hypervitaminosis as to chem. substances present in the prepn., since aldehydes, lactic acid, pyruvic acid, H<sub>2</sub>O<sub>2</sub>, B<sub>2</sub>O<sub>3</sub>, etc., are known to produce similar effects.

A. W. DOX

The distribution of fecal sterols of man on mixed diet. M. BÜRGER AND W. WINTERSEEL. Univ. Clinic Kiel. *Z. physiol. Chem.* 181, 255-63(1929).—It has been generally assumed that the sterols of human feces consist almost wholly of coprosterol, this substance being formed by bacterial hydrogenation of cholesterol in the intestine. By detn. of their Br-adding capacity it is now shown that only 50% of the fecal sterols is present as coprosterol, the remainder being chiefly cholesterol. From 10 to 30% of these sterols are excreted as esters. The ratio of cholesterol to coprosterol is fairly const. for normal subjects, whether on milk diet, mixed diet, or after a 5 g. dose of cholesterol in 100 g. olive oil. Detn. of the sterol balance shows that only about half of the 5 g. dose is eliminated during the first 6 days. The relatively const. ratio of the 2 sterols, despite wide variations in abs. amts. and dietary factors which would influence the bacterial flora, makes it appear probable that the hydrogenation of cholesterol is not due entirely to intestinal bacteria. Moreover, patients with impaired fat and cholesterol absorption (liver cirrhosis) excrete relatively less of the alimentary cholesterol as coprosterol although the bacterial flora remains normal.

A. W. DOX

Relative energy value of alfalfa, clover and timothy hay for the maintenance of sheep. H. H. MITCHELL, W. G. KAMMLADE AND T. S. HAMILTON. Univ. of Ill. Agr. Expt. Sta., *Bull.* No. 317, 127-67(1928).—Two expts. were carried out with 35 sheep. In the first expt. 0.15 lb. linseed meal plus sufficient of the 3 hays under investigation to maintain body wt. were fed. The av. amt. of feed per day per 100 lb. live wt. was, for alfalfa 1.92, clover 1.59 and timothy 1.82 lb. The av. amts. of metabolizable energy per day per 100 lb. live wt. required for maintenance were 1864 cal. for alfalfa, 1521 cal. for clover and 1507 cal. for timothy. Clover hay has a slightly higher net energy value than alfalfa hay. The net availability of the metabolizable energy of alfalfa was distinctly lower than that of the clover or timothy hays. No differences were noted between the latter 2 hays. Both control and surviving animals were subjected to chem. analysis. Emaciation increased the H<sub>2</sub>O content of all tissue samples above that of well-nourished tissues. In the emaciated sheep the ratio of protein to moisture in the flesh was 1:4.13, while in the well-fed animals this ratio was 1:3.8. The losses of constituents from well-fed to under-nourished sheep carcasses, expressed as percentages of the losses in live wt., averaged 24.8 for H<sub>2</sub>O, 4.6 for protein and 72.3 for fat. The av. loss contained 3.05 therms of gross energy per lb. The metabolizable energy of timothy hay is considerably better utilized in the maintenance of sheep than is the metabolizable energy of alfalfa hay. Since, in general, the metabolizable energy per unit of dry matter is nearly the same for the 3 hays, the net energy content of timothy hay will average considerably higher than that of alfalfa hay, in accordance with the

results of Armsby's calorimetric expts. on steers. Undernutrition withdraws fat from the muscular and glandular tissues before the marrow fat is affected. The withdrawal of fat from all tissues is accompanied by an increase in the ratio of protein to moisture. Neither the compn. of the wool nor its chem. growth is greatly affected by under-nutrition. C. R. F.

**Vitamin D content of the liver oil of the dogfish.** H. N. BROCKLESBY. *Can. Chem. Met.* 13, 74-7 (1929).—Liver oils from dogfish caught in various localities have been examd. for vitamin D to find a possible substitute for cod-liver oil in poultry and animal feeding. Vitamin D was found in all samples examd., the values varying with the locality from less than 10% to about 30% of the potency of medicinal cod-liver oil. Poultry-grade cod-liver oil has approx. half the vitamin D potency of the medicinal grade. The course of the expt. rickets was followed by means of x-rays and fecal pH. S. B. FOSTER

**The nephropathogenic action of cystine.** GERALD J. COX, C. V. SMYTHE AND C. F. FISHBACK. Univ. of Ill. *J. Biol. Chem.* 82, 95-103 (1929).—Young rats developed acute toxic nephrosis when restricted to synthetic diets. contg. 0.3 to 0.9% cystine. Such rats may, at times, recover and grow normally without any change in the ration. ARTHUR GROLLMAN

**Vital staining and vital accumulation in experimental pigeon beriberi.** WERNER KOLLATH. *Klin. Wochschr.* 8, 444-5 (1929).—The oxidation-reduction potential of the living tissue appears to be definitely reduced in beriberi. Methylene blue and trypan blue are reduced less completely in beriberi animals than is the case in normal animals. Starvation markedly increases the reducing ability of the tissues. Beriberi appears also to increase tissue permeability. Thus a piece of beriberi tissue, from a pigeon that had been treated with methylene blue, immersed in  $(\text{NH}_4)_2\text{MoO}_4$  becomes blue in the interior more rapidly than does a piece of tissue from a normal pigeon. M. H.

**Has irradiated ergosterol been administered in unnecessarily large doses?** P. GYÖRGY. *Klin. Wochschr.* 8, 684-91 (1929).—The heretofore prescribed doses of irradiated ergosterol have been excessive. The max. therapeutic dose need not exceed 1 mg. per day. Recovery from rickets is, perhaps, slower than with the larger doses but the therapy is certain and harmless. Very severe cases of rickets, with tetany, should be given 2-3 mg. daily for a short time. It appears as if 0.1-0.5 mg. per day was an ample prophylactic dose. Administration of 2-4 mg. per day does not elevate the Ca content of the serum and does not produce deleterious effects. Injury from this treatment has been due entirely to excessive dosage. MILTON HANKE

**Vitamin content of honey.** EDWARD HOYLE. Lister Inst., London. *Biochem. J.* 23, 54-60 (1929).—Fresh samples of English comb honey and West Indian honey are deficient in vitamins A, B<sub>1</sub>, B<sub>2</sub>, C and D. BENJAMIN HARROW

**Experimental infection of young hogs with ascarides with special attention to A-avitaminosis.** TEIICHI HIRAIISHI. *Arch. Schiffs-Tropen Hyg.* 32, 519-21 (1928).—Animals fed with a vitamin-A-poor diet are more easily infected. FRANCES KRASNOW

**Physiological action of extract of vitamin B.** MARIE SKARZYŃSKA-GUTOWSKA. *Med. Doswiadzalna i Spoieczna* 9, 1-16, 161-77, 181-2 (Polish), 177-81 (French) (1929); cf. C. A. 23, 867.—The action of vitamin B, extd. from wheat bran, on secretory phenomena of digestive glands, on kidney, on circulatory phenomena and respiration is described. The secretion of salivary glands and pancreas does not change after intravenous introduction of exts. of vitamin B. In chronic cases the intensity of secretion of stomachal glands after introduction of 2 cc. per kg. wt. of vitamin B ext. is  $5\frac{1}{2}$ -6 times weaker than after introduction of 0.5 mg. of histamine. Atropine diminishes the effect of the ext. In vivisections no effect was observed. The secretion of kidney increases slightly. The diuretic bodies are found in the crystals of exts. obtained by dialysis. The secretion takes place in 2 phases: immediately after introducing the ext. the vessels of the kidney are contracted and dilatation follows after 2-3 mins. This period corresponds with vit amin diuresis. After intravenous administration of 0.5-1 cc. per kg. wt. in dogs (vivisection) a decrease and later an increase of blood pressure are observed. The dog dies after doses larger than 3 cc. Atropine decreases this action. The action of vitamin B ext. on isolated organs as the heart, vessels of the kidney and intestines was studied and the presence of biologically active substances in the ext. as choline, K salts and probably histamine is proved by methods of Le Heux, Kramer and Tisdall (cf. C. A. 22, 3200, 3437). The expts. are accompanied by 20 photographs. J. K.

**The influence of food upon longevity.** H. C. SHERMAN AND H. L. CAMPBELL. *Proc. Nat. Acad. Sci.* 14, 852-4 (1928).—The influence of 2 diets upon the longevity of the albino rat has been detd. Diet A consisted of  $\frac{1}{2}$  dried whole milk and

$\frac{1}{4}$  whole wheat while diet B contained  $\frac{1}{3}$  dried whole milk and  $\frac{2}{3}$  whole wheat. In each case NaCl to the extent of 2% of the weight of the wheat was added; distd. water was given *ad libitum*. The rats were kept until death from natural causes. With males and females on diet B the av. duration of life was almost 10 per cent longer than with diet A. The attainment of definite degrees of longevity was in favor of diet B. It is suggested that food plays a very important role in the longevity of man.

G. H. W. LUCAS

**A contribution to the antimony trichloride reaction for the detection of vitamin A.** PAUL KARRER, BETH VON EULER AND HANS VON EULER. *Arkiv Kemi, Mineral Geol.* 10B, No. 2, 6 pp. (1928).—Since exts. do not give a consistent or const. color reaction with  $\text{SbCl}_3$  reagent, the application of the reagent is limited. If 10 animals are used in an expt., the results come within 30–50% of the results obtained by pure biol. methods. This leads to the belief that the reaction with  $\text{SbCl}_3$  is not due to a single substance but to a group as carotinoids or polyenes.  $\text{SbCl}_3$  was dried and dissolved in anhyd.  $\text{CHCl}_3$  to make a 30% soln.; the reading was made 10 secs., after mixing, in a tintometer. The substances used were recrystd. until a const. m. p. was attained. Relative readings of the blue color formed show the distribution as: carotin 100, bixin 160, xanthophyll 41,  $\gamma$ -crocetin 350, and dihydro- $\alpha$ -crocetin 240. Absorption spectra show: bixin in  $\text{CHCl}_3$  has 2 bands  $\lambda = 510\text{--}492$  and  $479\text{--}467$  with max. at 506.5 and 472.0  $\mu$ . The first max. is the most intense. A weak band lies at  $452\text{--}442$   $\mu$ . Bixin in  $\text{CS}_2$  shows the same form as in  $\text{CHCl}_3$  but is shifted toward the red. Absorption bands were at  $528\text{--}507$ ,  $494\text{--}483$  and  $464\text{--}455$   $\mu$  with max. at 518 and 488  $\mu$ . Xanthophyll in  $\text{CHCl}_3$  0.0355 mg. % and in a layer 7.93 mm. thick shows 3 bands at  $489\text{--}475$ ,  $460\text{--}445.5$  and  $435\text{--}427$   $\mu$  with max. at 482, 452.5 and 430  $\mu$ . The first band is most intense; the last is weak. Dihydro- $\alpha$ -crocetin 0.0036 mg. per cc. and in a layer 20.04 mm. thick shows 3 bands at  $380\text{--}388$ ,  $359\text{--}368$  and  $340\text{--}349$   $\mu$  with max. at 386, 365 and 346  $\mu$ . With greater concns. a 4th band appears at  $324\text{--}332$   $\mu$  with a max. at 329  $\mu$ . After an addn. of 0.2 cc. of a dihydro- $\alpha$ -crocetin soln. (4.5 g. in 25 cc.  $\text{CHCl}_3$ ) to 2 cc. of the 30%  $\text{SbCl}_3$  soln., an intense absorption band appeared in the red  $621.5\text{--}586$   $\mu$  with a max. at  $604.5$   $\mu$  in a layer 5 mm. thick. Bixin showed a band in the red extending to  $\lambda = 610$ . Xanthophyll (0.205 mg. per cc. alc.) in a layer 5.03 mm. thick shows a band in the ultra-violet ( $321\text{--}341$   $\mu$ ) with a max. at  $\lambda = 330$   $\mu$ .

FRANK MARESH

**Vitamin A in animal bodies.** BETH VON EULER AND HANS VON EULER. *Arkiv Kemi, Mineral Geol.* 10B, No. 3, 6 pp. (1928).—Vitamin A occurs in measurable quantities in the serum of bovines as indicated by the  $\text{SbCl}_3$  reagent. Ox blood (100 cc.) was extd. with an excess of ether; the collected exts. were distd. to a small vol. The small vol. was dried with anhyd.  $\text{Na}_2\text{SO}_4$  and the remaining  $\text{Et}_2\text{O}$  was evapd. The fat residue was dissolved in 2.5 cc.  $\text{CHCl}_3$ . To 0.2 cc. of this soln. was added 1.8 cc. 30%  $\text{SbCl}_3$  soln. and the resulting color showed 7 Lovibond (blue) units. Carotin, lycopin, capsanthin and xanthophyll give a blue color with  $\text{SbCl}_3$  in much greater dilm. Capsanthin shows a wide absorption band in the green. The reaction is characteristic for carotinoids and the  $\text{SbCl}_3$  is attached to the conjugated double bond (polyene group). The intensity and color reaction are displaced with the change in structure of the polyene group and may be influenced by other portions of the mol. The color reaction is a group reaction, and not all of the carotinoids can be vitamin-A precursors. Ox blood showed 17 Lovibond units per 10 cc. serum; hog blood contained 0.9 unit per 10 cc. of serum; black-tailed rats contained 1.6 units per 10 cc. of serum; and human blood showed 2.3 units per 10 cc. of serum. An ext. of 10 cc. of serum from a guinea pig which had been fed on carrots for 14 days showed no blue coloration after the addn. of the  $\text{SbCl}_3$  reagent. A human subject 64 years old, anemic: hemoglobin  $\frac{36}{100}$ , erythrocytes 3,250,000, S R = 30, showed no measurable blue coloration from 6 cc. of serum and the total amount of carotinoids was  $\frac{1}{8}$  of the carotinoid content of normal serum. This shows a relationship between the lipochromes and anemia or high-fat deposits. The lipochromes function as oxidation-reduction catalysts and participate when an aldehyde is added, or the polyene acids of the crocetin stearin ester type may give rise to ergosterol esters. Liver is a storehouse for fat-sol. vitamins, and with the  $\text{SbCl}_3$  reagent, ox liver showed 168 Lovibond units per g., pale-red rat liver 230, and brown-red rat liver 33. The pale-red liver is seldom found in rats and is higher in carotinoids than the normal brown-red liver. Dry livers also show an important carotinoid content. The above probable relation between anemia and carotinoid content on the one hand, and the definite therapeutic function of dry liver preps. on the other, render possible the belief that carotinoids function with the anti-anemia agent in the liver.

FRANK MARESH

The reversibility of the alterations in the experimental beriberi of the pigeon. II.

**RICCARDO REITANO.** *Boll. soc. ital. biol. sper.* 3, 960-5(1928).—The pigeons were kept under observation and killed after 4, 6, 7 and 9 avitaminosis attacks. The results showed that the animals gained their former wt. rapidly after each attack when yeast and corn were fed to them for 8 days. Paralysis of the lower limbs, anorexia and diarrhea also disappeared. Previous attacks did not render the animal more susceptible to the later attacks. The changes caused by feeding polished rice are, therefore, reversible if an adequate amt. of yeast and corn is administered to the animals. Details are given touching upon certain anatomic-pathological changes observed in the central and peripheral nervous system, heart, intestine, liver, pancreas, kidneys, spleen lungs and the suprarenals of pigeons afflicted with exptl. beriberi. **PETER MASUCCI**

Is avitaminosis a sufficient explanation for beriberi in man? **J. TRABAUT.** *Bull. acad. méd.* [3], 101, 47-9(1929).—A report of sporadic cases of beriberi when enough mixed food was given to counterbalance the rice. **A. E. MEYER**

The antiscorbutic factor. Its relations to the drying process. **P. LAVIALLE.** *Bull. sci. pharmacol.* 36, 129-33(1929).—Adult dogs were fed with a meal prepd. from biscuit powder and milk by evapn. at low temp. The addnl. food was overheated for a time. During 18 months no symptoms of scurvy appeared. A young dog, subjected to the test after weaning, developed scurvy after 6 months. **A. E. MEYER**

Comparative variations of the water content of the blood and the globular resistance in the normal guinea pig and in the guinea pig kept on a diet free from antiscorbutic vitamin. **L. RANDOIN AND A. MICHAUX.** *Compt. rend.* 188, 729-31(1929); cf. *C. A.* 22, 3913.—The method of Widal and Abrami with red corpuscles freed from plasma was used. The blood of normal guinea pigs contains 81.4 g.  $H_2O$  in 100 g. In animals nourished with a diet free from vitamin C, the  $H_2O$  content is increased after 3 weeks. It is 91% after 28-32 days, when death occurs. In scurvy, the resistance of the red corpuscles against hemolysis is diminished, if the limit of beginning hemolysis is considered; total hemolysis is obtained sooner in the blood of normal animals. This is due to the presence of young corpuscles in larger amt., by consequence of the frequent hemorrhages connected with scurvy. **A. E. MEYER**

Alimentation and nutrition. **H. ROGER.** *Presse méd.* 1929, 65-7.—A report concerning the progress in alimentary research of the last years. **A. E. MEYER**

The characteristic of the alimentary glucemia curve. IV. Sucrosemia. **V. V. OPPEL.** *Metchnikoff Hospital, Leningrad. Biochem. Z.* 205, 31-46(1929).—The introduction of 2-4 g. of sucrose per kg. by means of the stomach tube causes glucemia with a slight fructosemia (not exceeding 12 mg. per 100 cc. blood), but the presence of a sucrosemia cannot be demonstrated. This is not due to the impermeability of the intestinal wall because when sucrose is introduced directly into the jejunum there is occasionally sucrosemia. When sucrose is injected intravenously, there is a curve showing the regular disappearance of the sucrose from the system, the time of its disappearance depending upon the initial level. V. Fructosemia. *Ibid* 47-62.—Fructose administered to rabbits by means of the stomach tube can be detected in the blood, the concn. of the fructose in the peripheral blood depending upon the degree of loading. The first traces of fructose appear in 5 mins.; the disappearance comes  $2\frac{1}{2}$  to 3 hrs. later (when 2-3.5 g. per kg. have been administered), but the max. rise in the blood is not very striking and is 8-10 mg. per 100 cc. blood. Following the intravenous injection of 0.2-0.4 g. fructose, it disappears from the blood in 30-60 mins. Part of the injected fructose is retained by the liver while another part escapes into the general blood stream through the larger circulation. The max. fructosemia depends upon the mode of the introduction of the fructose, i. e., whether through the stomach or through the intestine. The stomach protects the organism against a too rapid absorption. The fructosemia curve is detd. by a variety of conditions: the function of the stomach, small intestine, liver and of the various tissues; a disturbance of any of these affects the character of the fructosemia curve. **S. MORGULIS**

Studies on the blood-sugar regulation in mammals. II. The effect of fasting on alimentary hyperglucemia. **BRUNO KISCH, A. SIMONS AND P. WERYL.** *Univ. Köln a. Rh. Biochem. Z.* 205, 349-59(1929); cf. *C. A.* 23, 2748.—In rabbits which fasted 9 days the glucemic reaction produced by feeding 6-20 g. oats or 1.5 g. glucose dissolved in 30 cc.  $H_2O$  is about the same, or if anything, somewhat less than in rabbits fasting only 16 hrs. In dogs this glucemic reaction following feeding of glucose is greater in animals that fasted 2-11 days, and lasts longer than in normal dogs. The hypoglucemia following the hyperglucemia is very marked in dogs fasting 1-3 $\frac{1}{2}$  days, is slight in dogs fasting 16 hrs. and does not appear at all in dogs after 7 $\frac{1}{2}$ -10 $\frac{1}{2}$  days of fasting. **S. MORGULIS**

The effect of thyroxine and of prephyson on the basal metabolism and the specific

**dynamic action following thyroidectomy or in avitaminosis.** A. V. ÁRVAY. Univ. Debreczen. *Biochem. Z.* 205, 433-40(1929).—In the matter of lowering the basal metabolism or the specific dynamic effect and of the influence of thyroxine there is a striking parallelism between the behavior of thyroidectomized rats or of rats on a vitamin-A- and B-free diet. Prephyson has absolutely no effect on the basal metabolism or specific dynamic action of thyroidectomized rats or of rats suffering from avitaminosis. Thyroxine raises the basal metabolic rate and the specific dynamic effect in both types of rats above the normal level. In 2 avitaminosis rats with hypertrophied adrenals, adrenalectomy caused rapid death, whereas 3 control rats survived the operation.

S. MORGULIS

**The effect of large amounts of iron. II. The effect of iron on blood, growth, fertility and lactation.** K. WALTNER. Univ. Kinderklinik, Szeged. *Biochem. Z.* 205, 467-72(1929).—The addn. of 2% reduced Fe to a complete diet has no effect upon the blood of exptl. animals (hemoglobin, no. of erythrocytes). But when this amt. of Fe is added to a rachitic diet it causes a marked anemia, and, furthermore, it shows a tendency to stunt the growth of the animals susceptible to rickets. Older animals do not suffer this effect of the added Fe. The reduced Fe in the proportion of 2% of the total food damages the fertility of both sexes, but this effect is offset by vitamin D. The Fe likewise exerts an unfavorable action on lactation which is again remedied by vitamin D.

S. MORGULIS

**Studies on carbohydrate-poor nutrition.** PAUL GYÖRGY AND HERMANN KELLER. Kinderklinik, Heidelberg. *Biochem. Z.* 206, 120-35(1929).—Young rats (15-25 days old) show practically the same rate of growth on a practically carbohydrate-free diet as do others on a similar synthetic diet contg. carbohydrate. Both kinds of diet, however, are inferior to a normal mixed diet. The practically carbohydrate-free diet has no hypoglycemic effect on the young growing rats or even a tendency to a lowering of the blood sugar. The fat and protein metabolism must therefore completely satisfy the body's requirement for carbohydrate. Protein-rich feeding leads to a relative kidney hypertrophy. It is cautioned against applying the results of these studies to the feeding of infants since the age of the exptl. rats did not correspond to that period of growth.

S. MORGULIS

**The specific dynamic action and the vegetative nervous system.** STEFAN ÉDERER AND JOSEF WALLERSTEIN. Univ. Pécs. *Biochem. Z.* 206, 334-9(1929).—Since the specific dynamic action can be completely suspended through paralysis of the sympathetic nervous system it is concluded that the N. sympathicus must play a dominant role in the mechanism of the specific dynamic action. The degree of the specific dynamic action depends upon the tone and irritability of the sympathetic. Furthermore, since the specific dynamic effect appears immediately after the consumption of food before any absorption of food could exert any influence it is also concluded that the depots of the organism must be at once mobilized. This depot may be glycogen since after depletion of the liver glycogen there is no specific dynamic action exerted by sugar. Evidently the organism avails itself of the reflex paths of the sympathetic system to effect a quick mobilization, the reflex ensuing from the intestinal mucosa. The process may be similar to the alimentary hyperglucemia which can be repressed through ergotamine. All sympathetic stimuli should therefore increase the specific dynamic action, and the different specific dynamic type curves are nothing but an expression of the constitutional vegetative balance.

S. MORGULIS

**Experimental studies on rickets. I.** E. M. LEPSKII, S. A. YEGOROVA AND E. E. MICHLINA. Lenin-Inst., Kasan. *Zhur. Exptl. Biol. Med.* 10, 501-6(1929).—Under special precautions it is possible to produce regularly rickets in young rats on a definite diet if they are kept in the dark. The usual tests for the identification of rickets were employed. McCollum's "line test" was employed in the recovery study. **II.** Antirachitic effect of dolphin oil. *Ibid* 508-13.—The oil of *Delphinus delphis* contains considerable amts. of the antirachitic protective substance, and 0.01 cc. is sufficient to prevent rickets in young rats on a Pappenheimer-Sherman rachitic diet. In animals with rickets the "line test" betrays definitely signs of healing after 8 days of administering 0.01 cc. of dolphin oil. **III.** The antirachitic effect of seal oil. *Ibid* 514-9.—Seal oil also offers protection to young rats in doses of 0.01 cc. per day. After 7 days' treatment with 0.04 cc. per day rachitic rats show definite results of healing in their bones.

S. MORGULIS

**Influence of the periodic administration of a vitamin-containing food (cabbage) on the development of scurvy.** K. M. MICHAÏLOV. State Univ., Moscow. *Zhur. exptl. Biol. Med.* 10, 618-20(1929).—The daily feeding of cabbage (40 g.) is not essential for guinea pigs and may be replaced by an intermittent feeding. Guinea pigs receiving

this amt. of cabbage every third day have thrived well for half a year, gaining 23-33% in wt. Feeding cabbage every fourth day, on the other hand, caused the development of scurvy in a no. of the exptl. animals.

S. MORGULIS

**The digestion of lignin by ruminants.** F. ROGOZINSKI AND MLE. M. STARZEWSKA. *Bull. intern. acad. polonaise* 1927B, 1243-52; *Acta Biol. Expt. Warsaw* 1, No. 8, 1-9 (1928).—The chemistry of lignin and its physiol. aspects in metabolism have been studied by many investigators since the beginning of the last century. König and Honcamp's methods of study are faulty. Lignin plays no part in the formation of hippuric acid. The ruminant used was the sheep. The first ration was 400 g. dried potato, 140 g. flax cake, 6 g. NaCl, 6 g. hay ash, 340 g. oat straw (according to Beckmann). The second ration was the same as the first plus 500 g. oats straw and 40 g. lignin from oats straw (according to Beckmann). Each period of experimentation lasted 10 days. Feces was collected during the last 5 days; the first 5 days were periods of transition. To prep. lignin 500 g. chopped straw mixed with 4 l. 1.8% NaOH stood 72 hrs. at room temp. The brown ext. was decanted and neutralized with HCl, heated to boiling and placed in an autoclave for 2 hrs. The soln. was evapd. and desiccated at 100°. The residue formed homogeneous powder free from pentosans. The analysis showed ash 0.64%, C 62.42, H 6.25, CH<sub>3</sub>O 12.11, as the mean av. The amt. of lignin ingested was practically the same in weight as the amt. eliminated in the feces; therefore the conclusion is drawn that it is indigestible.

GEO. W. MUHLEMAN

**Relative vitamin A content of four oriental foods.** HARTLEY E. SHERMAN. *Philippine J. Sci.* 38, 1-7(1929).—By using white rats on a diet lacking vitamin A, and supplementing the diet with varying quantities of the following foods, it was detd. that Chinese persimmon and the flower of a day lily (*Henierocallis flava* L.) are rich in vitamin A, and bean curd contains a moderate amt.

N. M. NAYLOR

**Relative content of water-soluble vitamin B in 30 oriental foods.** HARTLEY E. SHERMAN. *Philippine J. Sci.* 38, 9-36(1929).—By using white mice and later checking the expts. with white rats, on a diet lacking vitamin B, supplemented with varying quantities of the following foods, it was detd. that Chinese persimmon, water chestnut (*Eleocaris tuberosa* Naves), fermented rice (*Oryza sativa* L.) and locust seed (*Robinia pseudoacacia*) do not protect from beriberi at any feeding level; lettuce (*Lactu sativa* L.), chrysanthemum (*coronarium* L.) and kohlrabi (*Brassica campestris* L.) are not growth-promoting at high feeding levels. Other foods which are sources of vitamin B are mung bean sprouts (*Phascolus aureus*), soy bean and sprouts (*Soya max* L.), sorghum (*vulgare* Persoon), arrowhead (*sagittaeifolia* L.), pumpkin (*Cucurbita pepo* L.), day lily, kohlrabi, gourd (*Lagenaria vulgaris* Ser. and *Luffa cylindrica* L.), a green leaf vegetable (*Ipomoea reptans* Poiret), chico (*Achras sapota* L.), melon (*Benincasa hispida* Cogniaux) and pawpaw (*Carica papaya* L.).

N. M. NAYLOR

**Relative water-soluble vitamin C content of 9 oriental fruits and vegetables.** HARTLEY E. SHERMAN. *Philippine J. Sci.* 38, 37-46(1929).—By using guinea pigs on a diet lacking vitamin C, and supplemented with varying quantities of the following fruits and vegetables, it was detd. that pomegranate, Chinese cabbage and coriander (*sativum* L.) are rich in vitamin C; water chestnut and lotus (*Nelumbium speciosum* Willdenow) are good sources of vitamin C; kohlrabi, princes feather (*Polygonum orientale* L.) and lettuce are low in vitamin C.

N. M. NAYLOR

**Certain proteins added to mung bean, or to white or red Sorghum vulgare, increase the fertility of mice.** HARTLEY E. SHERMAN. *Philippine J. Sci.* 38, 47-67(1929); cf. *C. A.* 16, 1467.—It was shown that a diet consisting of mung bean or of white or red *Sorghum vulgare* as the only protein gave normal wt. of white mice but subnormal reproduction. To increase fertility, the best supplements for a mung bean diet are fat-free peanut, gelatin or casein; supplements for white sorghum diet are mung bean, fat-free soy bean or peanut; supplement for red sorghum diet was difficult to det., though casein gave the most satisfactory results.

N. M. NAYLOR

**Stimulation of metabolism by alcohol.** L. D. SEAGER, D. J. VERDA AND W. E. BURGE. *Science* 69, 383(1929).—Expts. are described to det. whether alc. serves any purpose in the body other than as a source of heat and energy. Goldfish were allowed to live in the following solns., to which air was admitted: (1) 0.1% dextrose (control), (2) 0.1% dextrose with (a) a mixt. of amino acids, (b) a mixt. of fatty acids and glycerol, (c) abs. alc. Sugar detns. were made at the beginning of the expt. and again 30 hrs. later. Thus the effects of alc., fats and amino acids upon sugar metabolism were detd. directly. It was found that alc. stimulated sugar metabolism as much as fat and protein.

N. M. NAYLOR

**Investigation of the food value of fresh grape juices and wines from the standpoint of their vitamin contents.** (MRS.) LUCIE RANDOIN. *Bull. soc. hyg. aliment.* 16, 464-86

(1928).—The expts. on vitamin C were carried out on guinea pigs, and on vitamin B on pigeons, guinea pigs and rats. Fresh grape juice contains vitamin C, but the antiscorbutic power of this juice is considerably less than that of orange or lemon juice. For financial reasons the amt. of grape juice required to produce the same effects as lemon or orange juice was not detd. Fresh grape juice contains only a small quantity of antineuritic vitamin B, while the pulp and seeds contain even less, and possibly none at all. Expts. on pigeons indicated that fresh grape juice probably contains appreciable amts. of antiberiberi vitamin B, but confirmation would require carrying out expts. on white rats or further expts. on pigeons with products freed from antiberiberi vitamin B but contg. antineuritic vitamin B. Wine exhibited antiscorbutic properties with certain individual animals, but only to a very slight extent in every case; and these were destroyed by cong. in vacuum at low temp. to remove EtOH. Wine apparently contains only very small quantities of antineuritic vitamin B, but appreciable amts. of antiberiberi vitamin B; and again they are partly or totally destroyed by removal of EtOH. On cong. at low temp. in vacuum to  $\frac{1}{3}$  of its original vol. and filtering, wine gives a thick liquid which prevents the occurrence of the accidents due to total absence of vitamin B in the ration of rats. The expts. are not yet finished, the prolongation of life having reached 5 months at the time of publication. A. P.-C.

Colorimetric determinations of vitamin A. BETH VON EULER AND HANS VON EULER. *Svensk Kem. Tid.* 40, 242-4(1928) (In German); cf. C. A. 16, 3113; 17, 3527; 20, 222; 22, 4591.—The crude fat from ox-blood serum reacts positively to the Carr-Price vitamin A test (C. A. 20, 3020). Et<sub>2</sub>O ext. from carrots yields red crystals which were recrystd. and gave characteristic color with the Carr-Price reagent.

A. R. ROSE

The relation of antimony chloride reaction to vitamin A and carotin. BETH VON EULER, HANS VON EULER AND HARRY HELLSTRÖM. *Svensk Kem. Tid.* 40, 256-62 (1928) (In German).—The carotinoids from ox blood and carrots were prepd. by Et<sub>2</sub>O extn, crystn. from Et<sub>2</sub>O, washing with petroleum ether and recrystn. from CS<sub>2</sub> by adding absolute alc. Their identity was established by spectrophotometric measurements. Spectrophotometric and colorimetric (Lovibond) values on ox blood are in good agreement. One l. serum contains 9-10 mg. carotin and the red cells from 1 l. blood gave 6.4 mg. carotin by the Lovibond system and 5.2 spectrophotometrically. The Carr-Price SbCl<sub>3</sub> reagent for vitamin A was positive for these materials and these blue solns. were studied spectrographically. The pure carotin CHCl<sub>3</sub> soln. + SbCl<sub>3</sub> did not give a curve similar to one on cod-liver oil + SbCl<sub>3</sub> but when the carotin was dissolved in peanut oil a similarity became apparent. The positive SbCl<sub>3</sub> reaction, carotin content and vitamin A potency are all definitely related. Cf. C. A. 23, 3009. A. R. ROSE

The increase in virulence of the germs of swine erysipelas in pigeons suffering from avitaminosis. DINO NAI. *Biochim. terap. sper.* 15, 325-37(1928).—Pigeons on a normal diet and pigeons in which beriberi had been produced by a diet of 30 g. of polished rice per day were used for the expts. The bacilli of swine erysipelas were of Budapest stock; they were grown on agar contg. a small quantity of horse serum. A suspension of the bacilli in physiol. NaCl soln. was inoculated in 2 groups of pigeons, which died after a certain no. of days. The necropsy and the bacteriol. examn. revealed that erysipelas actually was the cause of their death. The max. dose not producing death of the animals was found to be 700,000 germs for the normal pigeons and 600,000 germs for the pigeons with avitaminosis. After the death of the latter animals, blood was taken from the heart and the bacilli present in it were grown on agar. When suspensions of these bacilli were inoculated in normal pigeons, the death of the animals was caused by doses being considerably smaller than the original fatal doses. Bacilli obtained by the same technic from normal pigeons and inoculated in normal pigeons caused the death of the animals in doses only slightly smaller than the initial fatal doses. Conclusion: The virulence of bacilli of swine erysipelas is increased at least 10-30 times by their passage through the organism of pigeons suffering from beriberi. By the passage through normal pigeons, the virulence of the bacilli is augmented 1-2 times.

G. SCHWOCH

The chemical composition of the tissues in avitaminosis A: phosphorus, lipid extract and cholesterol. M. JAVILLIER, Mlle. S. ROUSSEAU AND Mlle. L. ÉMERIQUE. *Compt. rend.* 188, 580-2(1929); cf. C. A. 22, 2399.—In expts. with mice which lack vitamin A in their diet, the animals were analyzed for lipid ext., fatty acids, cholesterol and lipid P. Compared with the controls, lipid ext. and fatty acids were greatly decreased, cholesterol remained approx. the same and lipid P was somewhat increased. In further expts., different organs of white rats were analyzed for the same constituents when the animals afflicted with xerophthalmia had lost 10% of their original wt.

In comparison with the controls, the lipid ext. was decreased in skin, liver and muscle; it remained approx. the same in spleen, lungs, kidney and heart, and it was greater in brains and bone. With the exception of the skin the organs examd. contained less cholesterol than did the controls. With the exception of skin and muscles the fall of the values for fatty acids and lipid P was not very pronounced. G. SCHWOCH

**Acidified milk in infant feeding.** F. I. KRAUSS. *J. Med. Soc. New Jersey* 25, 792-7(1928).—K. points out the value of cow milk acidified with HCl or org. acids. The advantages are: A pptn. of fine, flocculent curds occurs, which act as a mech. aid to digestion. On account of the reduced buffer action the enzymes and the HCl of the stomach are enabled to exert their max. activity. The fat digestion and the food and fluid absorption are increased. The growth of pathogenic bacteria is inhibited. The caloric content of this milk may be increased by addn. of carbohydrates. G. S.

**Significance of mineral metabolism. I. Preliminary report on the calcium and phosphorus contents of some Porto Rican food materials.** D. H. COOK and TRINITA RIVERA. Univ. Porto Rico. *Porto Rico Rev. Pub. Health Trop. Med.* 4, 65-9(1928).—Porto Rico imports about 50% of the energy required to furnish an adequate diet of 2800 cal. daily per capita. The Ca and P contents of the imported foods for 1926 were calcd., the calcs. being based on the ash analysis taken from Sherman's "Chemistry of Food and Nutrition." The imports furnished only 14-32% of the Ca and 40-71% of the P that they should contain in proportion to the energy they furnish. The other 50% of the energy requirement is met by Porto Rican foods. While the foods available to the poor population contain an adequate amt. of P, their Ca supply is too low to make up for the shortage in the imports. The values for Ca and P are given for a few Porto Rican foods analyzed by C. and R. Breadfruit contained 0.017% Ca, gaudules 0.041% Ca, white yautia 0.004% Ca and 0.36% P, yellow yautia 0.014% Ca and 0.41% P. G. SCHWOCH

**Tissue changes associated with vitamin A deficiency in the rat.** M. DAWSON TYSON and ARTHUR H. SMITH. Yale Univ. *Am. J. Path.* 5, 57-69(1929).—The principal changes assocd. with vitamin A deficiency in rats are (1) a metaplasia of cuboidal or columnar epithelium in certain parts of the body (sublingual glands, submaxillary glands, epithelium of the renal pelvis and of the trachea and bronchi); (2) epithelial hyperplasia in the tongue and renal pelvis; and (3) infection. Xerophthalmia, if not too severe, will clear rapidly with the administration of cod-liver oil and the weight curve rises abruptly. Following cod-liver oil administration abnormal epithelium and chronic or acute infection persist in the tongue and renal pelvis when the rat is apparently healthy. F. B. SEIBERT

**Paralysis and muscular degeneration in guinea pigs on a rice diet.** E. BROUWER. *Arch. néerland. physiol.* 11, 403-10(1926).—Guinea pigs were fed a synthetic diet consisting of 77 parts of polished rice, 10 parts of pure casein, 10 parts of sucrose, 2 parts of  $\text{CaHPO}_4 \cdot 2\text{H}_2\text{O}$ , 1 part of NaCl and filter paper for roughage. In the beginning the animals received 40 g. of grass daily to accustom them to the synthetic diet; then the grass was gradually diminished. On 1 g. of grass daily the animals died in 6 days; 2 g. kept them alive for 7 days; on 5 g. they died in 23 days; 30 g. of grass prolonged life still more. When 5 cc. of orange juice was given to supplement the diet, death occurred in 5 to 10 days. The animals all appeared quite well until shortly before death when paralysis of the fore limbs and neck appeared. Death was not due to intestinal stoppage and was not prevented by giving liquid paraffin, or 0.5 g. of cod-liver oil daily; from 1 to 2 g. of dried brewer's yeast sometimes prolonged life. Wheat straw plus 5 g. of orange juice daily prolonged life to 70 days. At post-mortem no degeneration of the peripheral nerves was detected but some of the cells of the anterior horn showed disintegration of the Nissl granules. Hyaline degeneration and calcification were present in many of the muscular fibers, and was more pronounced in animals which lived longer. The cause of this condition is at present unknown. M. H. SOULE

Liver oil of the basking shark (SCHMIDT-NIELSEN, SCHMIDT-NIELSEN) 27.

## G—PATHOLOGY

H. GIDEON WELLS

**Experimental studies on indican formation.** I. YOSHIO KIMAI. *Tohoku J. Exptl. Med.* 11, 504-44(1928).—Indican in the urine of guinea pigs increases after only a few hours' fasting; fasting for 10 days increases indican about 10 times in the urine of rabbits. The state of the appetite of exptl. animals and the amt. of indican in their urine are inversely related. Disinfection of the intestinal canal or administration of laxatives increases the amt. of indican in the urine. **Hyperindicanemia in nephritis**

is the result of increased formation as well as retention of indican. Indicanuria may be partly due to increased decompn. of body protein as a result of poor appetite and partly due to metabolic anomalies. II. *Ibid* 12, 75-80.—Previous work with rabbits in the early stage of U acetate nephritis showed that the total amt. of indican in the blood and urine is less than in the normal state. The expts. were repeated, guinea pigs being used. The indican retained in the body was measured and added to the indican excreted. Indican formation in nephritis increases. III. *Ibid* 81-7.—Fifty-nine indican detns. on 14 children, with details on clinical symptoms, are reported. Conclusion: Indican originates abacterially. B. C. BRUNSTETTER

The localization of a lesion in the brain by differential staining of blood smears. KENJI SHOJI. *Tohoku J. Exptl. Med.* 11, 604-11(1928).—Bilateral brain lesions produced in 223 rabbits caused in 7 cases a neg. peroxidase reaction of the myeloid leucocytes in the blood (the oxidase reaction was pos.). This picture developed 1.5-24 hrs. after the operations. The smallest lesion assocd. with the "peroxidase puncture" extended as far cranial as the foremost part of the Aqueductus Sylvii and includes in it the parts near the oculomotor nuclei. B. C. BRUNSTETTER

Cerebroside storage in Gaucher's disease. III. HANS LIEB AND MILOŠ MLADENOVIC. Univ. Graz. *Z. physiol. Chem.* 181, 208-20(1929); cf. C. A. 22, 261.—A case of splenohepatomegaly that had been diagnosed as Gaucher type showed the typical Gaucher lipid cells not only in the liver, spleen, lymph glands and marrow, but also in other organs where such cells had not been known to occur. It was therefore suspected that the case was not the Gaucher but rather the Niemann-Pick type where the stored lipoids are phosphatides instead of cerebroside. The fact that the  $\text{Et}_2\text{O}$  ext. contained considerable P had been interpreted as evidence of a high lecithin content. Examn. of the same material by L. and M. now shows that no phosphatides were present and that the lipid material was chiefly kersin. This is cited as an instance where an uncertain diagnosis on the basis of morphological findings may be definitely decided by chem. analysis. A. W. DOX

The blood sugar and diabetes. ISRAEL S. KLEINER. *J. Am. Inst. Homeopathy* 22, 322-7(1929).—A review with bibliography. JOSEPH S. HEFURN

Blood as a physicochemical system. VIII. Diabetic coma. D. B. DILL, A. V. BOCK, J. S. LAWRENCE, J. H. TALBOTT AND L. J. HENDERSON. Mass. Gen. Hosp. and Harvard Univ., Boston. *J. Biol. Chem.* 81, 551-74(1929); cf. C. A. 22, 2782.—"This paper illustrates the value of systematically studying the interrelation of the important variables in the blood, 3 at a time, and then seeking to coördinate the results into a coherent system. Facts which at first are bewildering and seem inexplicable can be fitted into a consistent pattern. If one is guided by certain established generalizations, chief among which is the mutual dependence of the important variables studied, it is possible in unforeseen ways to evaluate exptl. observations, by discarding those which are inaccurate and using those which are accurate. Thus from a few exptl. observations it has been possible in this instance to synthesize a physicochem. description of blood in diabetic coma, which the authors believe to be not far inferior to the best nomogram based upon full and accurate information." Bibliography and 2 case histories are appended. J. A. KENNEDY

The origin of malarial pigment. W. WARASI. *Arch. Schiffs-Tropen Hyg.* 32, 513-7(1928).—The pigment is not a simple excretion of the parasites which remains in the protoplasm as a nutrient residue. The malaria parasite manufactures its pigment either from assimilated foodstuffs or from body constituents. F. K.

Mercuric chloride as a diagnostic agent for trypanosomiases in camels. S. C. J. BENNETT AND P. A. C. KENNY. Veterinary Research Lab., Khartown. *J. Comp. Path. Therap.* 41, 341-53(1928).—Dil. solns. of  $\text{HgCl}_2$  are reliable in detecting trypanosoma soudanense infection in camels. One drop of serum is added to 1 cc. of 1-20,000 or greater diln. of  $\text{HgCl}_2$ . A pos. reaction is denoted by an opacity within  $\frac{1}{4}$  hr. This is more reliable than the formal-gel test. FRANCES KRASNOW

Some points in the chemical and biochemical side of cancer. ALBERT WILSON. *J. Trop. Med.* 31, 321-6(1928).—Review. FRANCES KRASNOW

Acid-base metabolism. Effects of administration of salt and of restriction of water. LUDWIG SCHOENTHAL. Washington Univ. School of Med., St. Louis. *Am. J. Diseases Children* 37, 244-51(1929).—The administration of NaCl with the feedings of infants, with no restriction of water, results in the following changes in the blood plasma: an increase in the concn. of base chloride; a moderate reduction of bicarbonate; a tendency for the reaction to shift to the acid side, and changes in both directions in water content as indicated by the protein concn. The corresponding urinary changes are: an increase in excretion of fixed base over fixed acid, and a decrease in György's

coeff. A slight or moderate febrile reaction may accompany these changes. The administration of concd. food with restriction of water produces similar changes and, in addn., an increase in serum protein concn. and a marked febrile reaction. E. R. M.

**Chemical changes occurring in the body as a result of certain diseases. IV. Primary pneumonia in children.** DAN C. DARROW AND ALEXIS F. HARTMANN. Washington Univ. School of Med., St. Louis. *Am. J. Diseases Children* 37, 323-34(1929).—The chief changes in the character of the blood plasma which may accompany primary pneumonia in children are: a decrease in the concns. of chloride, bicarbonate and total base; a low f.-p. depression, and a high normal  $p_H$ . The decrease in concn. of electrolyte with no compensatory increase in nonelectrolyte may account for the decrease in osmolar concn. indicated by the f.-p. depression. E. R. MAIN

**Determination of the amounts of base, chloride, free and total acidity in the gastric contents of children on whom gastrostomy had been performed and in the gastric contents of fasting, new-born infants.** JOSEPH STOKES, JR., GEORGE W. STEPHENSON AND THOMAS C. GARRETT. School of Med., Univ. of Penna. *Am. J. Diseases Children* 37, 565-72(1929).—The gastric contents of children on whom gastrostomy has been performed contain little free HCl, have a low total acidity and show a tendency for the concn. of base to exceed that of chloride. The gastric contents of new-born infants may contain from 14.4 to 57 milliequivs. per l. of free HCl, and from 17.4 to 67 milliequivs. per l. of total acid; they may have a concn. of chloride approximating that of the plasma, and a concn. of base much lower than that of the plasma. E. R. M.

**The elimination of oxalic acid in phlorhizin glucosuria.** G. VIALE, L. NAPOLEONI AND D. ROSSELLI. *Arch. sci. biol.* 13, 206 9(1929).—The expts. were made on 3 dogs kept on a const. diet of 40 g. meat per kg. body wt. and water as desired. One week after the diet was used, the urine was collected for 24 hrs. and assayed for oxalic acid. Then phlorhizin, 35 cg. dissolved in a bicarbonate soln., was injected subcutaneously for 3 successive days. The urine was assayed again for oxalic acid and for glucose. The av. amt. of oxalic acid eliminated before the injection of phlorhizin was 12.2 mg.; after the phlorhizin injections it was 12.2 mg. Phlorhizin, therefore, does not modify in any const. manner the amt. of oxalic acid eliminated by dogs kept on a fixed meat diet. PETER MASUCCI

**The diazo test in nephritis.** ROBERT A. KILDUFFE (with ELEANOR G. SPRINGER). Atlantic City Hosp., N. J. *J. Med., Soc. New Jersey* 26, 150(1929).—The diazo test was carried out in various diseases and always found to be neg. in syphilis, diabetes, acute CO poisoning, myocarditis, intestinal obstruction, septic arthritis, fractures, salpingitis, tuberculosis, acute cardiac failure, HgCl<sub>2</sub> poisoning, hydronephrosis, acute appendicitis and cerebral concussion. In the nephritis cases no relation was observed between the degree of nitrogenous retention and pos. diazo reaction. G. SCHWOCH

**The effect of parathyroid hormone and increased calcium metabolism on the growth of tumor tissue.** ALFRED GOERNER AND BENJAMIN G. P. SHAFIROFF. *J. Cancer Research* 12, 294-300(1929).—The effect of parathyroid ext. and increased serum Ca has been studied on the growth of Flexner Rat Carcinomas (F. R. C.) and the Crocker Fund Sarcoma No. 10. The Ca content of the F. R. C. has been increased but no inhibitory effect due to Ca was effected. The growth chart showed the tumor to be rapidly growing, 3 cases of metastases being recorded. The Ca content of Sarcoma No. 10 has not been increased, no difference of growth from the control being recorded. H. G. W.

**The carbohydrate metabolism of tumors. III. The rate of glucolysis of tumor tissue in the living animal.** CARL F. CORI AND GERTY T. CORI. *J. Cancer Research* 12, 301-13(1929); cf. C. A. 20, 238.—The tolerance limit of normal rats for intravenously injected Na *d*-lactate, the lactic acid content of blood and urine being used as an index, was at a rate of infusion of  $95 \pm 5$  mg. of lactic acid per 100 g. of body weight per hr. Rats with tumors weighing from 14.2 to 21% of their body weight showed a marked increase in the lactic acid content of the blood. When the tumors corresponded to less than 10% of the body weight, the lactic acid content of the blood was within normal limits. The intravenous lactic acid tolerance of tumor-bearing rats was decidedly lower than that of normal rats and the decrease in tolerance was fairly proportional to the size of the tumor. The lower tolerance is ascribed to the fact that the tumor produces a certain amt. of lactic acid which adds itself to the amt. of lactic acid which is being infused. By detg. the difference in the lactic acid tolerance between normal and tumor-bearing rats it was possible to ext. the rate of lactic acid production of the tumor tissue in the living animal. The values obtained varied between 570 and 800 mg. lactic acid per 100 g. of fresh tumor per hr. with an av. of 690 mg. The rate of glucolysis of the tumor *in vivo* depends on the blood sugar concn. At a normal blood sugar level of the tumor-bearing animals the glucolysis corresponds to one half the maximal

possible glycolysis of the tumor. The intravenous glucose tolerance of tumor-bearing rats is the same as that of normal rats.

H. G. WELLS

The metabolism of the chorionic epithelium, the maternal decidua and other tissues. W. BLAIR BELL, J. BROOKS AND M. JOWITT. *J. Cancer Research* 12, 369-91(1929).—An investigation of respiration and glycolysis of tissues has shown that the human decidua at full-term and the maternal rabbit mucosa underlying the implantation site show positive  $U$  values defined by Warburg as  $U = Q_M^{N_2} - 2Q_{O_2}$  in connection with which the following terms are defined.  $Q_{O_2}$  (respiration) cu. mm. of O taken up per hr. per mg. dry weight of tissue.  $Q_M^{N_2}$  (aerobic glycolysis) cu. mm.  $CO_2$  produced by glycolysis under aerobic conditions, calcd. for a medium showing no retention of  $CO_2$ , and stated per hr. per/mg. dry weight of tissue.  $Q_M^N$  (anaerobic glycolysis) is an analogous quantity to the above measured under anaerobic conditions. The human chorionic epithelium at full term and the rabbit chorionic epithelium earlier in pregnancy probably have a high glycolytic metabolism and positive  $U$  values. Dila. of the epithelium in the placenta makes it impossible to obtain definite figures for its metabolism. Other workers have not attempted to analyze placental metabolism. A review of the subject of glycolysis shows that positive  $U$  values are not assoc. with malignant tissues only. Various points relating to the subject are discussed.

H. G. WELLS

Physical-chemical observations on the problem of the malignant cell. G. I. ROHDENBURG AND A. BERNARD. *Z. Krebsforsch.* 28, 301-10(1929).—Malignant tissues suspended in certain salt solns. take on less wt. than benign tissue. In the majority of cases malignant cells lose weight if suspended  $1\frac{1}{2}$  hrs. in a salt soln. corresponding to the blood of animals bearing retrogressing tumors. The addn. of colloids to such a salt soln. causes loss of wt. in benign tissues. Analysis of salt solns. after use for suspension of tissue fragments shows no marked changes, beyond that the tumor tissue gives up somewhat less N than normal tissue, and that despite the loss of wt. tumor tissue takes up Na from the soln. and gives off K. Electrodialysis in a simple system shows that the ion migration is not proportional to the total salt content of the dialysis fluids, nor to the relation of the single salts or iqns. The addn. of a colloid to different solns. has a small but distinct action on the migration of ions, sometimes increasing, sometimes depressing. An attempt is made to apply these observations to the behavior of tumor tissues in the body.

H. G. WELLS

The diagnostic value of Botelhos' reaction and Roffo's neutral red reaction in malignant tumors. B. S. ACEVEDO. *Z. Krebsforsch.* 28, 311-5(1299).—Neither reaction is sp. although they give 55-72% pos. reactions, for they give from 9 to 25% pos reactions with non-cancerous serum. They are not cachexia reactions, there being no relation between the condition of the patient and the result of the reaction. There may be a relation to the altered globulin-albumin ratio.

H. G. WELLS

The influence of avitaminosis on inoculated mouse tumors. OTTO THIES. *Z. Krebsforsch.* 28, 338-55(1929).—No definite effects were observed under the conditions of the expts.

H. G. WELLS

Carcinoma, plant growth, surface tension and permeability. J. TRAUBE. *Z. Krebsforsch.* 28, 356-61(1929).—Substances are present in tumors and the blood of tumor patients that affect surface tension and which may be a factor in the growth and behavior of tumor cells. This article consists of a discussion of this factor and of permeability augmentation, and their relation to the effects of radiation and other agents on tumor growth.

H. G. WELLS

Blood-calcium distribution in anaphylaxis in the guinea pig. HERMAN BROWN AND SUSAN GRIFFITH RAMSDELL. Research Inst. Cutaneous Med. *J. Exptl. Med.* 49, 705 9(1929).—The results for total Ca and the membrane-diffusible fraction in the serum of the guinea pig, taken at various intervals during anaphylactic shock, confirm the findings of previous workers that the total Ca is essentially unchanged. The diffusible fraction is considerably increased over that found for the animal similarly treated but not manifesting characteristic symptoms.

C. J. WEST

Precipitable substances of bacilli of the salmonella group. J. FÜRTH AND K. LANDSTEINER. Rockefeller Inst. Med. Research. *J. Exptl. Med.* 49, 727-43(1929); cf. C. A. 22, 986.—Sp. precipitable substances rich in carbohydrates, contg. very little protein and small quantities of a material apparently of fatty nature, have been prepd. from the main serological types of the typhoid-paratyphoid groups. The preps. in their present state of purity do not exhibit very pronounced chem. differences in spite

of serological dissimilarity. In this respect the results differ from those observed with the polysaccharides of pneumococci. The specificity of the precipitin reactions of these substances parallels in a general way the so-called small flaking agglutination. Attempts to sep. different fractions from the active substance serologically by means of pptn. with antibody solns. were on the whole unsuccessful. The differences in resistance to the action of acid and alkali were found to be characteristic for various sp. carbohydrates. C. J. WEST

**Production of partial liver insufficiency in rabbits.** PHILIP D. MCMASTER AND D. R. DRURY. Rockefeller Inst. Med. Research. *J. Exptl. Med.* 49, 745-58(1929).—A rapid and simple method for the production of marked liver insufficiency in rabbits has been described. The changes as concern blood sugar, urea formation and uric acid metabolism would appear to be the same in the rabbit suffering from hepatic insufficiency as in the dog. C. J. WEST

**Total surgical removal of the liver in rabbits.** D. R. DRURY. Rockefeller Inst. Med. Research. *J. Exptl. Med.* 49, 759-64(1929).—Rabbits deprived of the liver in the manner described if given glucose live for varying periods up to 40 hrs. Before death they show the same disturbances as do hepatectomized dogs. They die early, of hypoglycemia, unless provided with sugar. C. J. WEST

## H—PHARMACOLOGY

A. N. RICHARDS

**Influence of ethyl alcohol on the excretion of purine substances.** L. LA GRUTTA. *Riv. patol. sper.* 2, No. 3, 185-96(1927).—Large doses of EtOH cause an increase in the destruction of proteins and nucleins, and hence an increase in the amt. of their decompn. products in the urine. Moderate and small doses reduce the excretion of total and purine N and of P. Immediately after the ingestion of moderate or large doses of alc. a temporary disturbance of the ratio urea N/purine N is observed. B. C. A.

**The hypertensive action of ephedrine.** TATSUKE SUZUKI. *Tohoku J. Exptl. Med.* 12, 87-96(1928).—Ephedrine in dosages of 0.03 g. per kg. body wt. was intravenously injected into rabbits. The av. increase in blood pressure in 18 expts. on 6 normal rabbits was 33 mm. Hg (10-60 mm.); the av. duration of the increase was 35 mins. (6-76 mins.). In a series of 13 expts. on 4 rabbits with cut splanchnic nerves, the av. increase in blood pressure was 15.4 mm. Hg (5-30 mm.), lasting on the av. 8 mins. (1-27 mins.). The blood pressure was lowered in one expt. In a third series of 17 expts. on 5 adrenalectomized rabbits, the blood pressure fell in 3 cases; the av. of the increases was 24 mm. Hg (10-60 mm.), with an av. duration of 23 mins. (1-68 mins.). B. C. B.

**The autonomic nervous system in the regulation of blood sugar.** J. P. ALVAREZ. *Rev. méd. Barcelona* 8, 235-84, 344-63(1927); *Physiol. Abstracts* 13, 310.—Pilocarpine increases the blood sugar, but after adrenalectomy increases the hypoglycemia. Choline chloride causes a fall in blood sugar in man and rabbit, but not in the dog. When the nervous connections between adrenal and liver are destroyed, asphyxia causes a fall in blood sugar, which reaches a min. after 1 hr. Recovery is very slow. H. L. D.

**The action of quinine stovarsolate on Plasmodium falciparum infections.** F. VAN DEN BRANDEN. *Bull. soc. path. exot.* 20, 727-8(1927); *Rev. hyg. méd. prév.* 51, 309.—The action upon the gametes is more marked than quinine and not as active as plasmoquine but action is practically nil against the schizonts. Quinine stovarsolate is better tolerated by the circulatory system than plasmoquine. C. R. F.

**A new treatment of malaria by plasmochine.** F. VAN DEN BRANDEN AND E. HENRY. *Bull. soc. path. exot.* 20, 728-37(1927); *Rev. hyg. méd. prév.* 51, 310.—Plasmochine is a salt of alkylamino-6-methoxyquinoline. It is not a deriv. of quinine. Its administration may sometimes produce tachycardia which disappears after rest. The dose is 0.02 grain thrice daily for 4 days, followed by 4 days of rest, then a repetition of the treatment for 4 more days. Cure is consummated in from 4 to 6 weeks. Plasmochine has no action on the schizonts of *P. falciparum* but it causes the disappearance of gametes from the blood. It also acts similarly on all forms of *P. malariae*. The action on *P. vivax* was not studied. C. R. FELLERS

**Role of the tertiary amine function in the bipiperidine nucleus.** RENE HAZARD AND MICHEL POLONOVSKI. *Compt. rend.* 188, 822-4(1929); cf. *C. A.* 22, 1402.—*Granatoline* prepd. by the demethylation of the N-oxide (*C. A.* 22, 429) exercises a strong hypertensive action which appears to depend upon the peripheral vasoconstriction of the kidney. This action cannot be overcome by adrenaline. The action is equally intense following double suprarenalectomy. If the cardiac vagi are intact, there is an inotropic action and an accentuated negative chronotropic action. Small repeated

doses slightly diminish the amplitude of the heart contractions and slow down their rhythm; the pressure is slightly lowered. Larger doses decrease the excitability of the vagus. *N*-oxy-*N*-methylgranatoline injected intravenously into a dog (dose, several cc.) was practically without effect on the heart. The secondary non-methylated granatoline produced a physiol. action at least equal in intensity to that of the tertiary methylated base, i. e., *N*-methylgranatoline (tervalent N). The passage to the amine oxide (quinquevalent N) greatly decreases and practically nullifies physiol. activity. C. R. F.

**Demonstration of the action of lobeline and carbonic acid on the respiration of man in narcosis.** HERMAN FRANKEN. Univ.-Frauenklinik, Freiburg. *Klin. Wochschr.* 8, 439-42(1929).—A method is described for the graphic representation of respiration in man. The intramuscular injection of the customary dose of lobeline—0.01 g.—is not very effective as a respiratory stimulant. This is no reflection upon the effectiveness of this dose as a respiratory initiator in the new born. Lobeline is very effective in the new born. The action on the respiratory center is instantaneous when lobeline is injected intravenously. A dose of 0.0015 g. acts for 1 min. A single intravenous injection of 0.003 g. stimulates the vagus and leads to strangulation, coughing and intestinal contraction. These symptoms have been misinterpreted as signifying an awakening from the narcosis. CO<sub>2</sub> in concns. of 2-8% is a powerful respiratory stimulant. It can be administered at this level indefinitely. The action is persistent. MILTON HANKE

**The biological inactivity of ergosterol peroxide.** WOLFGANG HEUBNER AND FRIEDRICH HOLTZ. *Klin. Wochschr.* 8, 456-7(1929).—Ergosterol peroxide, irradiated or otherwise, does not possess antirachitic properties and has no effect upon the arteries.

MILTON HANKE

**The center that is acted upon by analgetics.** H. HOFF AND P. WERMER. *Klin. Wochschr.* 8, 488-91(1929).—Atophanyl or pyramidone reduces the sensitiveness to pain on both sides of the body in normal individuals and in most persons that are afflicted with nervous disorders. These analgetics do not elevate the pain threshold on the affected side in persons with a diseased thalamus, but show their normal action on the unaffected side. Morphine is uniformly effective in the latter cases. Pyramidone and atophanyl act upon the thalamus.

MILTON HANKE

**Poisoning with dimethyl sulfate.** H. STROTHMANN. *Klin. Wochschr.* 8, 493-6(1929).—Symptoms, prognosis, treatment and case reports are given. Poisoning (more properly called corrosion) is usually due to the vapor. The mucous membranes are the ones affected. The symptoms may vary from a slight conjunctivitis and a raw throat to a complete asphyxia due to a swelling of the bronchi. The active agent is probably the H<sub>2</sub>SO<sub>4</sub> that is produced from the (CH<sub>3</sub>)<sub>2</sub>SO<sub>4</sub> by hydrolysis. MILTON HANKE

**Carbohydrate metabolism and the catabolism of the glucose molecule.** I. ERICH SCHNEIDER AND ERNST WIDMANN. *Klin. Wochschr.* 8, 536-41(1929).—Dihydroxyacetone, injected intravenously into rabbits, is oxidized immediately. The reducing power and the lactic acid content of the blood are not increased. The respiratory quotient goes from 0.81 to 0.92. Lactic acid, injected intravenously, acts primarily as an acid and reduces the alkali reserve. The animal dies if the amt. injected exceeds 350 mg per kg. body wt. A single, sub-lethal dose leads to an immediate but transient elevation in the lactic acid content of the blood. Blood sugar is not affected. Repeated sub-lethal doses elevate the lactic acid content of the blood and, after a time, the blood sugar is also markedly increased. The lactic acid is, at first, synthesized to glycogen. The glycogen storage capacity of the liver is, however, limited so that, after a time, glucose is produced from the glycogen and appears in the blood. Methyl glyoxal is highly toxic. The lethal dose is 0.3 g. per kg. rabbit. The lactic acid content of the blood rises instantaneously after the injection of methyl glyoxal. Methyl glyoxal is converted instantaneously into lactic acid. The animal dies if the amt. of lactic acid produced is sufficiently high. Repeated sub-lethal doses of methyl glyoxal lead first to lactic acid formation, then to glycogen formation, etc., as in the case of lactic acid.

MILTON HANKE

**Chronic mercury poisoning.** ARTHUR HERTZ. *Klin. Wochschr.* 8, 541-4(1929).—Extensive bibliography of the recent literature. Hg was always found in the feces or urine of persons whose teeth were filled with amalgam. The feces always contain more than the urine. Curiously, however, 11 out of 15 patients that did not have amalgam fillings and had not, to their knowledge, ever been in contact with Hg, gave a pos test for Hg in the feces. Symptoms of poisoning were never noted in any of these cases. (Ag amalgam could hardly be a source of Hg. Most dentists, however, compound their amalgam by guess rather than by wt. and squeeze out the excess of Hg. The amalgam filling would, in such cases, be a source of Hg for a considerable period time.)

MILTON HANKE

The therapeutic influence of metal salts on infectious diseases. H. LYDING. *Klin. Wochschr.* 8, 553(1929).—Walburn (*C. A.* 21, 963) claims that 90% of infectious diseases in mice can be cured by administering CsCl. I. finds that CsCl, Hg(CN)<sub>2</sub>, ZnO and CdCl<sub>2</sub> have no effect upon mouse infections. MnCl<sub>2</sub> has a beneficial action upon poisoning due to diphtheria or tetanus toxin. MILTON HANKE

Genesis of the eosinophilia associated with ascaris infection and eventually also with other diseases due to worms. I. The action of aliphatic aldehydes. W. BORCHARDT. *Klin. Wochschr.* 8, 591-4(1929).—Very small doses of simple aliphatic aldehydes (excepting AcH) give rise to an eosinophilia. Larger doses lead to hyperneutrophilia. These aldehydes are normal constituents of ascaris and other worms. M. H.

Comparative effect of adrenaline on the blood pressure and intestinal motility in the dog. C. A. DRAGSTEDT AND J. W. HUFFMAN. *Am. J. Physiol.* 85, 129-34(1928); *Physiol. Abstracts* 13, 466-7. E. H.

Investigations on the toxicity of Ascaris. TAKEO SAKAGUCHI. Keiō Univ. *Arch. Schiffs-Tropen Hyg.* 32, 517-8(1928). FRANCES KRASNOW

Treatment of African sleeping sickness with germanin (Bayer 205). Critical discussion of results and proposals. MARTIN MAYER. Institut für Schiffs- und Tropenkrankheiten zu Hamburg. *Arch. Schiffs-Tropen Hyg.* 32, 528-42(1928).—The drug is very beneficial for early cases. FRANCES KRASNOW

Results of therapeutic research with plasmochin in Bulgarian villages suffering from malaria. A. KIR DRENOWSKY. *Arch. Schiffs-Tropen Hyg.* 32, 575-80(1928).—Patients take plasmochin more readily than quinine. The former drug is effective in daily dose of 0.01 g. per 10 kg. body fat. It is especially valuable in quinine resistant cases. Plasmochin seems to have a specific action on the sexual form of all malarial parasites, which within 3 days after treatment disappear from the peripheral blood. F. K.

The question of secondary effects due to phasmochine. O. FISCHER AND G. RHEINDORF. Inst. Schiffs- und Tropenkrankheiten zu Hamburg. *Arch. Schiffs-Tropen Hyg.* 32, 594-7(1928).—No untoward effects have thus far been noticed. F. K.

Plasmochine as an active antimalaria remedy. L. I. LEISERMANN. Ukrainischen Inst. Protozoenforchung. *Arch. Schiffs-Tropen Hyg.* 32, 598-605(1925).—Cases are too few for final conclusion. In acute malaria, phasmochine brings about rapid cure. FRANCES KRASNOW

Distribution of arsenic in the body after repeated poison potions. S. SCHÖNBERG. Institut für ger. Med. Basel. *Deut. Z. ges. ger. Med.* 13, 111-4(1929).—Arsenic was found in the liver, kidneys, brain, skin and fur of the exptl. animals (rabbits). F. K.

The use of intramine in therapeutics. HERBERT H. HODGSON. Tech. College, Huddersfield. *J. Comp. Path. Therap.* 41, 164-5(1928).—Correction in regard to credit due to priority. FRANCES KRASNOW

Phytopharmacological and photopharmacological studies on leprosy blood serum. DAVID I. MACHT. Johns Hopkins Univ. *J. Philippine Islands Medical Assoc.* 8, 523-4(1928).—The serum of leprosy sufferers is markedly toxic for *Lupinus albus*. Exposure to ultra-violet irradiation did not detoxify it. FRANCES KRASNOW

Omnadin in whooping cough. RAYM. OZYNULA. *J. Philippine Islands Med. Assoc.* 9, 61-3(1929).—Good results in 60 cases. FRANCES KRASNOW

Granuloma venereum—its diagnosis and treatment. Notes of fifteen cases treated with "stibenyli" Heyden in British Guiana. GEORGE GIGLIOLI. *J. Trop. Med.* 31, 245-54(1928).—Stibenyli Heyden is a powerfully active drug for the treatment of granuloma. It is efficient in cases resisting tartar emetic, brings about a rapid cure with courses of 6 to 10 intravenous injections on alternate days and is well tolerated. FRANCES KRASNOW

Eserine and the thyroid apparatus. J. RÉGNIER, D. SANTENOISE, P. VAVÉ AND H. VERDIER. *Bull. acad. méd.* [3], 101, 109(1929).—The gland is first contracted, then expanded, and later contracted again. A. E. MEYER

Colloidal copper morrhuate in the treatment of tuberculosis. J. MOUZON. *Presse méd.* 1929, 358-9.—Report of results obtained with colloidal Cu morrhuate in South America. A. E. MEYER

The association of iodine and sulfur in therapeutics. M. ARMINGEAT. *Rev. méd.* 45, 967-9(1928).—S and I are used against rheumatism and sclerosis; separately they have little effect. Their action is a supplementary one. S must be applied in compd. but not oxidized; a compd. of S with I gives the best results. A. E. MEYER

The effect of glycooll and of *d*-glutamic acid on the non-fermentable reducing substances of the blood. FOLKE NORD. *Acta Med. Scand.* 70, 277-85(1929).—The reducing substances in the blood of rabbits were detd. after parenteral administration of glycooll and glutamic acid. The blood sugar was detd. by Folin's method either

in the usual way, or by substituting a 10% yeast suspension for the water and leaving the mixt. of blood and suspension to stand 10 mins. before adding the other reagents. In the normal rabbit there is 29 mg. % residual reducing substance (calcd. as glucose). Following an injection of 1-4 g. glycocoll per kg. of body wt. the residual reduction is on the av. 24 mg. % higher than before. After the injection of 2-3 g. glutamic acid per kg. body wt. the residual reducing power of the blood is practically unchanged although the total reducing power is enormously increased. Both amino acids, therefore, administered intravenously or subcutaneously give rise to sugar. S. M.

The carbohydrate balance of starving rats following insulin and adrenaline injections. CARL F. CORI AND GERTY T. CORI. State Inst. for Cancer Research, Buffalo, N. Y. *Biochem. Z.* 206, 39-55(1929).—Between 24 and 48 hrs. of fasting the total glycogen content of rats diminishes 22 mg. per 100 g. The constancy of the glycogen is attributed to the fact that fat oxidation furnishes the energy necessary to resynthesize the lactic acid formed in muscular activity. The av. respiratory quotient of rats fasting 24 hrs. is 0.715, and is not altered through the injection of adrenaline, although the  $O_2$  consumption is increased corresponding to the av. increase of 17.3% in the calories. Adrenaline thus increases the heat production of fasting rats at the expense of fat oxidation. Following insulin injections the respiratory quotient is somewhat raised while the  $O_2$  consumption is unchanged if the dose is carefully chosen. An overdose of insulin causes first a rise and later a fall in the  $O_2$  consumption. Three hrs. after an adrenaline injection (0.02 mg. per 100 g.) the av. muscle glycogen is 57 mg. less per 100 g. while the liver glycogen is 36 mg. higher. The increase in liver glycogen is interpreted as resulting from a synthesis of lactic acid derived from muscle glycogen. The muscle glycogen must, therefore, be considered an important, though indirect source of blood sugar. It is suggested that the adrenaline secretion makes muscle glycogen available to the organism in the form of blood sugar which is especially important for the fasting condition. Following insulin injection the muscle glycogen diminishes 34 mg., yielding a part of the total oxidized carbohydrate (56 mg.), but the liver glycogen already very low does not undergo any significant alteration. It is not to be expected that the carbohydrate combustion will be markedly raised in fasting animals whose liver glycogen is low, since insulin increases preferentially the consumption of blood glucose, or indirectly of liver glycogen in the peripheral tissues. S. M.

The mechanism of synthalin action. GUNNAR AHLGREN. *Biochem. Z.* 206, 99-108(1929).—Synthalin does not affect the methylene blue reduction reaction of animal tissues as does insulin, which alone slows the reaction and in combination with glucose causes acceleration. Synthalin, on the contrary, accelerates the reaction but in combination with glucose produces inhibition. This suggests that insulin and synthalin produce their effects at different points in the metabolic mechanism. A combination of synthalin with insulin produces no effect or an inhibition like synthalin + glucose, whereas all three substances together accelerate the methylene blue reaction even more than insulin + glucose alone. S. MORGULIS

Experimental studies on the insulin reaction. J. M. MACGILLIVRAY AND RICHARD WAGNER. Univ.-Kinderklinik, Wien. *Biochem. Z.* 206, 136-49(1929).—In diabetic children the blood-sugar curve, upon the administration of 10 insulin units, falls slower and to a much smaller extent when the patients are on a carbohydrate-poor and fat-rich diet than when their diet is one with a high-carbohydrate and low-fat content. S. MORGULIS

Comparative studies on the binding of some narcotics by lipid-rich and lipid-poor tissues. S. LOEWE AND P. MOLJAWKO-WYSSOTZKI. *Pharmakolog. Inst., Dorpat. Biochem. Z.* 206, 194-211(1929).—The adsorption of chloral and bromal hydrates by nerve and muscle tissue was studied and certain corrections were found necessary because the nerve tissue swelled while the muscle tissue tended to shrink. The use of salt soln as a solvent for the narcotics did not prevent the swelling phenomenon. Furthermore, an equil. state was established only after several days. Brain tissue binds more of the narcotics than muscle, though the difference is much less than a schematic lipid-selectivity would make one expect. S. MORGULIS

Observations on arsine poisoning. ERICH MEYER AND WOLFGANG HEUBNER. *Biochem. Z.* 206, 212-22(1929).—No methemoglobin could be found in the blood of the organism dead from arsine poisoning. The connective tissue appeared in various places filled with methemoglobin. The As content of the liver and kidney was 0.1 g., but the concn. in the organ was 10 mg. % in the kidney, and 3 mg. % in both liver and spleen. In a case of very severe poisoning the blood contained on the second day 13 mg. % As but the blood cells were free from As. The blood contained no methemoglobin while the urine contained much hemoglobin and methemoglobin. However, as soon

as the blood was exposed to the air for a few minutes the hemolyzed fluid portion showed the presence of methemoglobin but the cells were still free from this. Treated with arsine *in vitro* the corpuscles quickly acquire methemoglobin. The regular symptoms of the poisoning are painful sensation in the upper abdominal and lower chest region, vomiting and collapse. The urine contains albumin and granular casts even when there is no hemoglobin; also peculiar white cells appear in the blood. The As is excreted in amts. of 0.5-2.0 mg. per day, but is eliminated only partly. S. M.

Relation between the physiological action and the chemical constitution of 2-methylisoquinoline derivatives. T. TAKASE AND K. TERAUCHI. Tohoku Imp. Univ. Japan. *J. Pharm. Soc. (Japan)* 48, 978-81(1928).—2-Methylisoquinoline derivs., without an aromatic group on the side chain, whether or not they give phenylethylamine derivs. on cleavage, have similar physiol. action. The degree of physiol. action depends upon their chem. constitution. F. I. NAKAMURA

The comparative action of hypertonic solutions of the chlorates and chlorides of potassium, sodium, calcium and magnesium. JOHN I. ULRICH AND VLADIMIR A. SHTERNOV. Plant Research Lab., New Jersey. *J. Pharmacol.* 35, 1-15(1929).—The compds. were given *per os* and intraperitoneally to rats and guinea pigs. With each cation the chlorides were more toxic than the chlorates. The order of toxicity of the various compds. was as follows: Given *per os* or intraperitoneally  $\text{Ca}(\text{ClO}_3)_2 > \text{Mg}(\text{ClO}_3)_2 > \text{KClO}_3 > \text{NaClO}_3$ ; given intraperitoneally  $\text{MgCl}_2 > \text{CaCl}_2 > \text{KCl} > \text{NaCl}$ ; *per os*  $\text{KCl} > \text{MgCl}_2 > \text{CaCl}_2 > \text{NaCl}$ . No differences in toxicity were observed between KCl and  $\text{KClO}_3$ , or between NaCl and  $\text{NaClO}_3$ , when given intravenously to cats and rabbits. C. RIEGEL

The effect of drugs on the secretion of uric acid in the fowl. O. S. GIBBS. Dalhousie Univ., Nova Scotia. *J. Pharmacol.* 35, 49-62(1929).—The excretion of uric acid in the urine of the fowl is a good criterion of renal function because the hourly output is const.; any disturbance of renal function such as clamping of the ureters leads to prompt increase in uric acid in the blood; there is no storage of uric acid in the kidney, as evidenced by the fact that the amt. of uric acid secreted after clamping of the ureters is the same as before, that the blood uric acid rises immediately on clamping the ureters and that injected uric acid is recovered promptly in the urine. Drugs which act on the autonomic nervous system (atropine, pilocarpine, adrenaline, physostigmine) cause no change in blood uric acid content, or in mg. uric acid excreted, indicating that secretory processes in the kidney are not controlled by a nervous mechanism. That there is no relation between uric acid excretion and water excretion is shown by the fact that pituitrin decreases the vol. of urine while the amt. of uric acid excreted is increased, and that cinchophen causes no change in vol. of urine, while the output of uric acid is markedly decreased. This supports Mayrs' suggestion that uric acid is secreted as an active process, and not by a process of filtration-reabsorption. C. R.

Action of certain heterocyclic compounds on the autonomic nervous system. REID HUNT AND R. R. RENSHAW. Harvard Med. School and New York Univ. *J. Pharmacol.* 35, 75-98(1929).—The effect on blood pressure in cats and the fatal dose for mice of the following compds. are reported: (carboxymethyl)pyridinium bromide, (carbethoxymethyl)pyridinium bromide, (carbethoxymethyl)- $\alpha$ -picolinium bromide, (carbethoxymethyl)lepidinium bromide, (acetoxymethyl)pyridinium chloride, nicotinic acid hydrochloride, nicotinic acid Me ester,  $\beta$ -carbomethoxy-*N*-methylpyridinium iodide (cesol iodide),  $\beta$ -carbomethoxy-*N*-methyl-*N*-ethylpiperidinium bromide (neu-cesol), arecoline hydrobromide (*N*-methyltetrahydronicotinic acid Me ester), (carbethoxymethyl)piperidinium bromide, (carbethoxymethyl)methylpiperidinium iodide, (carbethoxymethyl)ethylpiperidinium bromide, acetoxyethylmethylpiperidinium iodide, diethylpyrrolidinium bromide, *N*-methyl- $\alpha$ -pyridone hydrobromide, *N*-ethyl- $\alpha$ -pyridone hydrobromide, *N,N*-dimethylhexamethylene ammonium bromide. The results indicate that the muscarine action (stimulation of parasympathetic nerves, a vasodilatation which is abolished by atropine) is independent of the presence of a quaternary N atom; addn. of an Ac group (as in acetoxyethylmethylpiperidinium iodide) or esterification (carboxymethylpyridinium bromide to carbethoxymethylpyridinium bromide) increases muscarine action; addn. of a Me group in the *o*-position to the N atom greatly reduces toxicity and physiol. activity (as in carbethoxymethyl- $\alpha$ -picolinium bromide); complete reduction of the ring (as in formation of carbethoxymethylpiperidinium bromide) causes lowering of toxicity and physiol. activity. C. RIEGEL

Some effects of derivatives of betaine amide and of choline ethers on the autonomic nervous system. REID HUNT AND R. R. RENSHAW. Harvard Med. School and N. Y. Univ. *J. Pharmacol.* 35, 99-128(1929).—The effect on blood pressure of cats, either anesthetized or with brain and upper cord destroyed, and the toxicity for mice, of the

following compds. is reported: betaine chloride, carbamylmethyltrimethylammonium chloride, *N*-methylcarbamylmethyltrimethylammonium chloride, *N*-ethylcarbamylmethyltrimethylammonium chloride, *N*-propylcarbamylmethyltrimethylammonium chloride, *N*-butylcarbamylmethyltrimethylammonium chloride, *N*-phenylcarbamylmethyltrimethylammonium chloride, *N*-*p*-hydroxyphenylcarbamylmethyltrimethylammonium chloride, *N*-*o*-methoxyphenylcarbamylmethyltrimethylammonium chloride, *N*-*p*-methoxyphenylcarbamylmethyltrimethylammonium chloride, *N*-*o*-ethoxyphenylcarbamylmethyltrimethylammonium chloride, *N*-*p*-ethoxyphenylcarbamylmethyltrimethylammonium chloride, *N*-*p*-tolylcarbamylmethyltrimethylammonium chloride, *N*- $\alpha$ -naphthylcarbamylmethyltrimethylammonium chloride, *N*- $\beta$ -naphthylcarbamylmethyltrimethylammonium chloride, carbipiperidinotrimethylammonium chloride, carbureidomethyltrimethylammonium bromide, carbphenylureidomethyltrimethylammonium bromide, phenoxyethyltrimethylammonium bromide, phenoxypropyltrimethylammonium bromide, dimethylphosphatoethyltrimethylammonium chloride, choline sulfuric acid ester, *N*-phenylcarbamylmethyltri-*i*-amylammonium bromide. When a phenyl group was substituted in the amide group of betaine amide (carbamylmethyltrimethylammonium chloride to *N*-phenylcarbamylmethyltrimethylammonium chloride) the muscarine action (fall in blood pressure which was prevented by a small dose of atropine and which occurred after a large paralyzing dose of nicotine) diminished, and the stimulating nicotine action (rise in blood pressure in a pithed and atropinized animal, which was prevented by a large dose of nicotine) increased. Substitution of a phenyl group in betaine ethyl ester or in choline also abolished muscarine action and in the latter compd. increased the blood-pressure-raising action. When the side chain was lengthened (phenoxyethyltrimethylammonium bromide to phenoxypropyltrimethylammonium bromide) nicotine action diminished. When a substituted phenyl group (as hydroxyphenyl, methoxyphenyl or ethoxyphenyl) was introduced (*N*-phenylcarbamylmethyltrimethylammonium chloride to *N*-*p*-hydroxyphenylcarbamylmethyltrimethylammonium chloride) the nicotine action was diminished or abolished, but muscarine action did not return. Compds. with substituted phenyl groups were more toxic than the phenyl deriv. When the H of the amide group in betaine amide was substituted by a Me (and to a less extent by an Et) group, or by a piperidino or carbureido group, muscarine action increased, while if the Me group was substituted in the methylene group of the esters of betaine the muscarine action diminished. Toxicity was parallel to increase in muscarine action. When a Ph group was substituted in the methylene group of betaine esters the muscarine action was depressed, but the stimulating nicotine action was not increased as it was by substituting the Ph group in the amide group of betaine amide. Most of the compds. had a paralyzing nicotine action. C. RIEGEL.

Changes in the tonicity of smooth muscle produced by toxins of *Ascaris lumbricoides*. CHESTER A. HERRICK AND FREDERICK E. EMERY. Univ. of Wisc. *J. Pharmacol.* 35, 129-41(1929).—Segments of intestines of rats, guinea pigs, cats and rabbits were placed in a bath of Locke's soln. and contractions recorded. To the bath were added small quantities of exts. prepd. from *Ascaris lumbricoides* of the pig. The exts. were made by treating either whole worms, various organs or dried worms, with water or physiol. saline soln. Very small quantities of the exts. (0.05 cc. or 5 mg. of dried material) caused increased tonus of the muscle and usually an increase in rate of contraction. Large amts. up to 600 times the smaller dose did not cause paralysis, but after the 1st addn. response of the muscle decreased. Washing with fresh Locke's soln. restored the original sensitivity. The rat intestine was the least sensitive, guinea pig the most. There was little difference in the intestine of cat or rabbit. Uteri of rabbits and cats gave the same type of response as intestinal segments. C. RIEGEL.

Quantitative measurements on the dilatation of pial blood vessels after the administration of nitrites in dogs. CHAUNCEY D. LEAKE, A. G. KAMMER AND J. B. HIRZ. Univ. of Wisc. *J. Pharmacol.* 35, 143-6(1929).—Intravenous injections of alc. solns. of glyceryl trinitrate were made into trephined anesthetized dogs. The area of the brain under observation was photographed before the injection and after at a time when the fall in blood pressure was at a max., and the size of the blood vessels measured on the photographs. The increase in size was 14-40% (av. 21%). An increase in the no. of vessels visible was noticeable after injection. C. RIEGEL.

The employment of strontium thioacetate as an antidote in poisoning by mercuric chloride. CHAS. C. HASKELL AND J. C. FORBES. Medical Coll. of Va. *J. Pharmacol.* 35, 147-53(1929).—Dogs were given HgCl<sub>2</sub> intravenously or orally followed by Sr thioacetate. In every instance the supposed antidote shortened the time of survival. Sr thioacetate alone, given intravenously, caused marked gastrointestinal disturbances. C. RIEGEL.

Some relative physiological properties of certain new 5,5-dialkyl- and 1-aryl-5,5-dialkylbarbituric acids. AXEL M. HJORT AND ARTHUR W. DOX. *J. Pharmacol.* **35**, 155-64(1929); cf. *C. A.* **22**, 1626.—The anesthetic actions of 5,5-dialkylbarbituric acids (5,5-ethylamyl, 5,5-diamyl, 5,5-ethyltetrahydrofurfuryl, and 5,5-dibenzyl derivs.), and of 1-aryl-5,5-dialkylbarbituric acids (1-phenyl-5,5-diethyl, 1-*p*-tolyl-5,5-diethyl, 1-*p*-anisyl-5,5-diethyl, 1-*p*-phenetyl-5,5-diethyl, 1-*p*-chlorophenyl-5,5-diethyl, 1-*p*-bromophenyl-5,5-diethyl, 1-phenyl-5,5-ethylpropyl, 1-phenyl-5,5-ethylbutyl, 1-phenyl-5,5-ethylisobutyl, 1-phenyl-5,5-ethylisoamyl) were studied on mice, the drugs being given intraperitoneally. Of the aryl derivs. all except 1-phenyl-5,5-ethylbutylbarbituric acid were obtained in cryst. form. The results were compared with the action of 5,5-ethylisoamylbarbituric acid, which had a min. anesthetic dose of 1.3-1.5 mg. per 20 g. and a M. L. D. of 3.75, the ratio of the 2 being 1:2.9. Of the 4 dialkyl derivs. only the ethylamyl deriv. was equal to the isoamyl deriv. in potency, the M. A. D. being 1.75-2.0 mg. per 20 g., the M. L. D. 4 mg. and the ratio 1:2.5. The other 3 derivs. were unsatisfactory because of a high M. A. D. and development of convulsions and paraplegia. None of the 1-aryl derivs. of 5,5-diethylbarbituric acid was of value as an anesthetic. All of the 1-phenyl 5,5-dialkyl compds. had higher M. L. D. and lower M. A. D. than the corresponding 5,5-dialkyl compds., the most favorable as an anesthetic being 1-phenyl-5,5-ethylbutylbarbituric acid with M. A. D./M. L. D. 1:15. 1,3-Diphenyl-5-ethylbarbituric acid and the *p*-phenetylmonouride of ethylbutylmalonic acid were found to have no anesthetic action. C. RIEGEL

The effect of peptone upon the hepatic veins in the dog. J. P. SIMONDS AND W. W. BRANDES. Northwestern Univ. *J. Pharmacol.* **35**, 165-70(1929).—Liver removed from dogs was placed in a closed box having inflow and outflow tubes, and an opening at the top for connection with a tambour to record changes in pressure in the chamber, and hence changes in liver vol. The outflow tube was connected with a manometer so that changes in perfusion rate could be recorded. Oxygenated defibrinated blood was used as the perfusion fluid. When the vol. and outflow became const., 0.2 to 1.0 g. Witte's peptone was introduced into the inflow tube. Perfusion pressure was kept const. throughout the expt. When perfusion was made through the portal vein, the vol. of the liver increased and the outflow decreased  $\frac{1}{2}$ , after peptone. When perfusion was made through the hepatic veins both liver vol. and outflow decreased after peptone was introduced. Conclusion: Peptone has a specific effect on the hepatic veins, causing an obstruction, probably the result of constriction. C. RIEGEL

The use of magnesium as an aid in anesthesia. ISAAC NEUWIRTH AND GEORGE B. WALLACE. N. Y. Univ. *J. Pharmacol.* **35**, 171-87(1929).—MgSO<sub>4</sub> was given subcutaneously to dogs in doses of 0.25-2.7 g. per kg. When the serum Mg rose above 5 mg. per 100 cc. the animal showed signs of depression, and these symptoms of depression increased with increasing size of dose (hence increasing serum Mg) until complete anesthesia was obtained with a serum Mg of 19.8 to 23.2 mg. per 100 cc. Serum Ca was sometimes decreased. Dogs given Mg lactate or rabbits given MgBr<sub>2</sub> by stomach tube showed no signs of anesthesia, and the Mg of the serum did not increase above normal. Dogs given by rectum a mixt. of Mg lactate, mineral oil and ether, or of MgSO<sub>4</sub>, Mg stearate, cottonseed oil and ether, showed no increase in serum Mg, nor was an increase in serum Mg noted in any of 3 patients given by rectum an aq. soln. of MgSO<sub>4</sub> (8 g.), morphine sulfate, chloral hydrate and glucose. In obstetrical analgesia 2 or 3 intramuscular injections of 2 cc. of 50% MgSO<sub>4</sub> failed to increase the Mg in the serum above 3 mg. Conclusion: The addn. of MgSO<sub>4</sub> to colonic anesthesia mixts., or its use in obstetrical analgesia in the doses advised, is useless. C. RIEGEL

Sterilizing action of repeated, fractional doses of arsphenamine in experimental syphilis. CARL VOEGTLIN. Hygienic Lab., U. S. Public Health Service. *J. Pharmacol.* **35**, 189-92(1929).—Rabbits infected with *T. pallidum* could be sterilized by repeated fractional doses of arsphenamine. C. RIEGEL

Studies on compensatory hypertrophy of the thyroid gland. VIII. A comparison between the effect of administration of thyroxine, thyroid and anterior pituitary substance on the compensatory hypertrophy of the thyroid gland in the guinea pig. LEO LOEB. Wash. Univ. Med. School. *Am. J. Path.* **5**, 71-8(1929); cf. *C. A.* **20**, 2201.—The inhibiting effect of feeding anterior pituitary substance on compensatory hypertrophy of the thyroid gland previously found by Loeb and Kaplan (*J. Med. Research* **44**, 557 (1924)) is confirmed. Anterior pituitary substance, thyroid substance and thyroxine all produce similar effects, not only preventing compensatory hypertrophy of the thyroid gland but also tending to produce changes in the gland that signify a resting condition. The anterior pituitary ext. is probably somewhat less potent than the others. IX. The influence of variations in size of the remaining part of the gland, in mode of adminis-

tration and in quantity of potassium iodide, on the hypertrophy of the thyroid in the guinea pig. *Ibid* 79-86.—Notwithstanding complicating factors, which are listed, it is probable that the administration of KI intensifies rather than diminishes compensatory hypertrophy. This is true even if only  $\frac{1}{4}$  of one lobe is left behind, and also whether the I is fed or injected intraperitoneally. F. B. SEIBERT

The effect of intraperitoneal injection of potassium iodide on the proliferative activity of the thyroid gland in guinea pigs. JACOB RABINOVITCH. Wash. Univ., Med. School. *Am. J. Path.* 5, 91-7(1929).—The intraperitoneal injection of KI for 10 days causes a very rapid increase in proliferation of the thyroid epithelium, as evidenced by the great increase in the no. of mitoses observed at this time. The increase is greater the larger the amt. of KI administered, within the range of the doses used. In these changes there is a characteristic difference from the corresponding changes in guinea pigs fed with KI. F. B. SEIBERT

Fate of acetylcholine in the blood. G. VIALE AND J. M. SONCINI. *Physiol. Inst. in Rosario. Arch. ges. Physiol.* (Pflüger's) 221, 594-8(1929); cf. *C. A.* 23, 646.—Acetylcholine and vagus substance are probably not identical. G. H. SMITH

The toxicity of thallium sulfate. J. C. MUNCH. *J. Am. Pharm. Assoc.* 17, 1086-93(1928).—Rats were fed with  $Tl_2SO_4$  and the M. L. D. was detd. as 0.0250 g. per kg. of body wt. This is about the same toxicity as strychnine for the rat. Tl is a certain but not a rapid rat poison. The M. L. D. for rabbits intravenously is about 0.025 g. per kg. It is toxic to children in doses of 0.008 g. per kg., and toxic symptoms have developed with half that dosage. Tl affects the sympathetic nervous system, causing alopecia, pains in the muscles and nerves of the legs, and disturbances of the endocrine glands, particularly the ovaries or testicles. L. E. WARREN

An unusual factor influencing action of some drugs on smooth muscle. DAVID I. MACHT. *J. Am. Pharm. Assoc.* 17, 1192(1928).—The tests consisted in suspending a healthy *vas deferens* freshly dissected from a rat in oxygenated Locke's soln. at 37-8° and recording its normal contractions. The activity with standard adrenaline soln. is first observed. After washing the organ, it is again tested with a soln. of a glandular product, e. g., corpus luteum. Marked contraction of the organ is caused by corpus luteum but it was observed that the same quantity of ext. did not always cause the same amt. of contraction on organs from different animals. Further study demonstrated that the *vas deferentia* of animals which had been kept in proximity to female rats and therefore in a continuous state of sexual excitement were more sensitive than were the organs of animals which had been kept far away from females for several weeks preceding the expts. L. E. WARREN

The effect of histamine on the secretion of gastric juice. F. GALLART MONES, JACINTO VILARDELL AND PEDRO BABOT. *Anales acad. med.-quirurg. españ.* 14, 907-8(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 231.—One mg. histamine (1:1000) causes no unpleasant symptoms when given to fasting subjects. Only transitory appearances were noted, as congestion of the face, decided vaso dilatation of the conjunctiva, fall of the arterial pressure and sometimes pain in the epigastrium. R. C. W.

The effect of histamine on the secretion of gastric juice. MOGENA. *Anales acad. med.-quirurg. españ.* 14, 683-707(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 230, cf. preceding abstr. and *C. A.* 22, 1804.—Intravenous injections of histamine have no effect on the secretion of gastric juices. The symptoms of peripheral vasodilatation were quickly removed by 0.25 mg. adrenaline. Subcutaneous injections of 0.5-1.0 mg. in 1 cc.  $H_2O$  decreased the amt. of gastric juice. The amt. of acid did not exceed 3.5% and after 250 cc. of tea was below 2%. The action of histamine was studied in cases of peptic ulcer, carcinoma, achlorhydria, colitis, pulmonary tuberculosis and gall stones. R. C. WILLSON

The parenteral ingestion of nitrogen and the elimination of nitrogen through the bile. ARNALDO BIASOTTI. Univ. Rome. *Arch. biol.* 5, 43-54(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 783.—Witte's peptone in sterile NaCl solns. caused no local irritation when injected into dogs with biliary fistulas. The amino acid N of the bile at first showed a slight increase but later sank; the highest elimination was 0.00076 g. per kg. per hr.; the later av. was 0.0005. Protein injections are not injurious to either man or the dog, as the injected proteins decomp., as they do in the gastrointestinal tract. The parenteral addn. of peptone is not injurious when it does not exceed 0.3 g. per kg., the kidneys being intact. R. C. WILLSON

Changes in the secretion and motility of the stomach through the influence of insulin and synthalin. LUIS G. BUSTAMANTE. Hosp. gen., Madrid. *Arch. endocrinol. y nutric.* 6, 295-333(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 791.—In a series of 29 cases which received 10 units insulin, 23 showed increased HCl, 3 a decrease

and 3 no change. Of 20 cases receiving insulin and 1 mg. atropine, there was 1 with an increase in HCl, 13 with decreases and 6 with no changes. Synthalin (25 mg.) caused an increase in 2 cases, a decrease in 4 cases and no change in 4 cases. Motility was studied fluoroscopically, 7 of 8 cases showing an increase after insulin. After insulin-atropine the motility was unchanged in 2 cases and decreased in 1 case. R. C. WILLSON

**The importance of the placenta for the neutralization of poisons.** G. DE LAURETIS AND S. MARTINES. Univ. Bologna. *Arch. ostetr. e ginecol.* 14, 489-522(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 142.—Lethal doses of different poisons and the poisons plus finely divided placenta tissue were injected into frogs of equal wt. When placenta tissue is added to strychnine the convulsions appear late but the subsequent action of the poison is unchanged; however, there was no strychnine action when the placenta of an eclamptic patient was used. The effect of liver and kidney tissue on the action of strychnine is the same as that of placenta. There is no reaction when a fatal dose of quinine is administered with placenta, thymus or spleen; kidney and uterus do not have this effect. The action of nicotine was irregular. R. C. WILLSON

**The importance of the suprarenal capsule for the sedative action of morphine on the intestine.** I. Studies on the intestine of the rabbit in situ. TSUNEMICHI HAYAMA. Univ. Kyoto. *Folia pharmacol. japon.* 7, 128-36(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 284.—The subjects were laparotomized rabbits in the Trendelenburg position. Intravenous injection of 0.005-0.01 g. morphine intravenously inhibits the motor function of the intestine. In the absence of the suprarenal function or after splanchnicotomy, morphine has no action on the intestine except in rare instances when it is irritating. II. Studies of the adrenaline secretion in the rabbit. *Ibid* 137-45.—In normal rabbits the intravenous administration of 0.005-0.01 g. morphine-HCl per kg. — which has an inhibiting action on the motor function of the intestine—effected a large increase in the adrenaline content of the blood (Trendelenburg method) and a sharp rise in the blood pressure (carotid artery). In the absence of suprarenal function or after splanchnicotomy these increases were absent. R. C. WILLSON

**The reticulo-endothelial apparatus.** IV. The changes of the blood picture in animals receiving injections of trypan blue and ferrum oxidatum saccharatum. MARIO CAPOCACCIA. *Haematologica* 8, 321-48(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 46, 236.—After the injection of toxic amts. of trypan blue and ferrum oxidat. sacch. an oligocythemia appears. This is proportionate to the amt. and concn. of the injected soln., but is not related to a cell-destroying function of the reticulo-endothelial system, since it enters only after toxic doses and since histologically no traces of an increased cell-destroying activity are found in the cells of the reticulo-endothelial system. The monocytosis which is present is limited by an increase in the normally present monocytes and through the formation of large, free endothelial cells. The latter cells are differentiated in morphology and in their behavior from the true monocytes and must be regarded as a deriv. of the reticulo-endothelium irritated by the injections. R. C. WILLSON

**So-called water intoxication.** HIROTADA MISAWA. Imp. Univ., Tokio. *Japan. J. Med. Sci.* 1, 355-83(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 693.—At intervals of 30 mins., 50 cc. tap H<sub>2</sub>O per kg. body wt. was given to rabbits. This caused restlessness, polyuria, diarrhea, salivation, dyspnea and tremor. After about 4 hrs., the administered H<sub>2</sub>O amounting to about 1/3 of the total body wt., convulsions appeared. Blood tests at this time showed a decrease in the dry substance to about 15%; decrease of 23.5% in the serum protein, the protein quotient remaining unchanged; reduction of Cl, P, Na, K, Ca and Mg to about 20%; slight reduction in the residual N, hemoglobin and red cells; increase in the blood sugar, f. p. (0.14°) and white cells and a percentage increase in the leucocytes. The animals were killed by bleeding and the results of tests on the organs compared with controls. The H<sub>2</sub>O content of all organs in the test animals was increased; Cl content of the liver increased but decreased in all other organs, the greatest increase showing in the skeletal muscles. The urine Cl, Na, Ca, P and N were increased; Mg was unchanged and K decreased. Further H<sub>2</sub>O administration caused death. Body temp. decreased 2° when convulsions appeared. R. C. WILLSON

**The influence of various drugs on the internal pressure of the bladder.** SH. UCHIGAKI. Imp. Univ., Kyoto. *Japan. J. Obstet. & Gynecol.* 10, 47-50(1927); *Ber. ges. Physiol. exptl. Pharmacol.* 45, 813.—After laparotomy a manometer was attached to the bladder of rabbits and the intravesicular pressure recorded. Drugs were given intravenously. Pilocarpine-HCl (0.25 mg.) caused sustained increase in pressure and frequency of movements. This effect was abolished by atropine sulfate (0.25 mg.). Physostigmine sulfate (0.1 mg.) caused transient increase in pressure; 0.2 mg. caused

brief violent movement followed by sharp rise in pressure. This is abolished by morphine. The chief effect of adrenaline is a decrease in pressure and movement. Nicotine tartrate (0.1–1.0 mg.) caused alternate rise and fall in pressure. Morphine-HCl (0.1–0.3 mg.) caused a temporary increase, 2.5 mg., a slight decrease. Cocaine-HCl (2.5–25 mg.) caused a rise in pressure and movement. Quinine-HCl (5 and 25 mg.) caused a brief rise followed by a sharp fall in pressure.  $\text{BaCl}_2$  did not influence the lowered pressure.  $\text{BaCl}_2$  (2.5 mg.) increased movement and pressure. Strychnine nitrate (0.002 mg.) increased pressure and periodic movement; 0.2 mg. caused spasms and great increase in pressure. Pituitrin (5 mg.) effected increase in pressure. Urotropine (5 cc. 40%) decreased and then increased pressure and increased movement. The urine following urotropine was strongly alk. and increased in vol. R. C. WILLSON

Active glucosides from *Adonis vernalis*. K. FROMHERZ. F. Hoffmann-La Roche, A.-G., BASEL. *Münch. med. Wochschr.* 75, 818–20 (1928).—Two highly active, digitalis-like glucosides were isolated from *Adonis vernalis*. Both possessed all known characteristics of glucosides. They differed in their action on the heart. The one which has a weak action on the heart has a sedative action and is a strong diuretic. Their action is not cumulative. R. C. WILLSON

The active constituent of *Rhododendron hymenanthos* Makino, "Rhodotoxin." II. Further studies of the pharmacological action. MAKATO MAKINO. Univ. Okayama. *Okayama-Igakkai-Zasshi* 40, 138–54 (1928); *Ber. ges. Physiol. expil. Pharmacol.* 46, 287.—Continuing former studies (cf. C. A. 23, 1691) M. studied the action of rhodotoxin on some lower animals. Small doses of rhodotoxin produce a diminution of the respiratory frequency and of the depth of the respiratory movements in the rabbit. The respiratory vol. per time unit is lowered. As the dose is increased the decrease of the respiratory frequency and vol. becomes more marked and finally there is respiratory depression with Cheyne-Stokes breathing. Larger intravenous doses cause a transient acceleration of the respiration. The emetic action of the poison is not influenced by severance of both vagi in the cat. It thus appears that there is no central action. The poison lowers the blood pressure in the rabbit, but after larger doses there is an increase which is regarded as secondary to the respiratory disturbance and the muscular spasm. When applied to the peripheral vessels, as the femoral vessels of the frog and the aural vessels of the rabbit, the poison causes a dilatation. In the frog studies, when higher concns. are used a slight constriction follows this dilatation. When applied to the frog heart, either isolated or *in situ*, rhodotoxin in small doses has a slight stimulating action, while larger doses paralyze. The resected small intestine and uterus of the rabbit and earthworm muscles, the nerve cords having been removed from all, are stimulated by the poison. The tonus is increased and the amplitude enlarged. The skeletal muscles are resistant to its action. Small doses increase the urinary output; larger ones inhibit it. Rhodotoxin is not very active on earthworms and infusoria. A hemolytic action was not observed. Concns. less than 0.5% cause no local irritation of the mucous membrane. R. C. WILLSON

The action of adrenaline on the isolated frog heart. S. V. ZIGNOV. *Med. Staatsinst., Odessa. Zhur. expil. biol. med.* 8, 437–49 (1928); *Ber. ges. Physiol. expil. Pharmacol.* 45, 560.—Hearts of *R. esculentae* were perfused with isotonic sea water. The min. effective concn. of adrenaline is 1:5 billion. The action consists in increased frequency, increased systole, decreased diastole; hence decreased pulse vol. Cardiac output usually is decreased but may be increased or unchanged. The reaction is greater at 18–23° than at 7–15°. Straub's method gives lower results when used to test sensitivity to adrenaline. R. C. WILLSON

New phenolic combinations obtained by coupling chaulmoogric acid with resorcinol (HINEGARDNER, JOHNSON) 10. Diphenylaminearsonic acid. I. Derivatives of diphenylamine-4-arsonic acid (BARBER) 10. The Landecker (thermal) springs in the light of the latest balneological investigations (LACHMANN) 14. Germicidal activity of diarylsulfide phenols (HILBERT, JOHNSON) 10.

## 12—FOODS

F. C. BLANCK AND H. A. LEPPER

Technical aids in the preparation of food products. I. A. BEHRE. *Altona. Chem.-Ztg.* 53, 217–8 (1929).—A review of the various factors bearing upon the com. prepn. of foods. The addn. of colloidal substances to foods in the course of pres improves their general condition. The "added-substances" discussed are flour,

and vegetable albumin, sugar or Ca succinate, tragacanth, egg yolk, agar, gelatin, pectin, etc. Meat products, mayonnaise, milk products, bread and egg-dough products are included. II. *Ibid* 238-9. A study of confectionery, molasses and table sirup, marmalades, jellies, ices and ice cream, "march-pane," chocolate and alc. beverages.

RUSSELL C. ERB.

**Chemical analyses of 37 oriental foods.** HARTLEY E. SHERMAN AND TSAN CH'ING WANG. *Philippine J. Sci.* 38, 69-79(1929).—Analyses for water, fat, ash, protein, carbohydrate, crude fiber and fuel value are tabulated for 37 native Chinese foods. This group of foods consists of most of those mentioned in this series of articles, also wild rice, eggs, squash, burdock, yam, rape, certain sirups made from fermented grains, and a variety of seeds.

N. M. NAYLOR

**A calcium, iron and magnesium content of 16 Chinese foods.** HARTLEY E. SHERMAN AND TSAN CH'ING WANG. *Philippine J. Sci.* 38, 81-2(1929).—A tabulation is given showing the Ca, Fe and Mg content of certain dry seeds, of the seed sprouts from hydrant water and from distd. water. The Ca content of sprouts from distd. water is lower than that of sprouts from hydrant water. The seeds and plants tested are those mentioned in these papers, including green beans, mung beans, wild rice, rape, chrysanthemum, kohlrabi and squash.

N. M. NAYLOR

**Fluorescence-analysis from the standpoint of testing materials especially in regard to foods and condiments, etc.** MAX HARTINGER. *Mitt. staatl. tech. Versuchsanst. (Wien)* 17, Nos. 1, 2, 3, 147-56(1928).—Whole milk fluoresces a canary-yellow, but upon standing, this color centers in the cream and the rest of the milk finally ceases to fluoresce, becoming white. Normal skimmed milk likewise fluoresces yellow so that no analytical application is made. Filter paper and cotton take up this yellow fluorescence; very quickly the color is diluted and the adsorbent becomes white after a time. *Salicylic acid* (as an example of a preservative) in heated milk (0.5 g./l.) shows blue on filter paper. *Dried milk* fluoresces lighter than fresh milk; whole milk powder cannot be differentiated from skimmed milk powder. *Butter* fluoresces like milk; *artificial fats*, in masses, show white or yellow mostly with a blue luster and often a direct blue. In thin layers such fats are blue entirely. Different fat solvents yield different fluorescence. *Eggs and albumin* from fresh eggs, when raw, show nil, but upon heating, a canary-yellow fluorescence is obtained. Old egg albumin yields a blue. The *shells of eggs* are rose to dark red under the quartz lamp. Other colors given are: *French olive oil*, bluish white; *Dalmatian olive oil*, weak rose; *Italian olive oil*, silver-gray; *technical olive oil*, red to rose-yellow; *sesame oil*, lustrous lilac; *soy bean oil*, light lilac; *peanut oil*, light gray; *castor oil* (first press), light blue and (second press), yellow; *refined oils*, lilac; *technical refined or exld. oils*, yellow; *raw oils*, dark with a faint blue. Mineral oils cannot be confused with such oils, as mineral oils give other characteristic reactions. A large number of other food substances are listed and described with fluor-analytic possibilities.

R. C. E.

**Manganese in foodstuffs.** CLIVE NEWCOMB AND G. SANKARAN. Pasteur Inst., Coonoor. *Indian J. Med. Research* 16, 788-98(1929).—Mn is detd. as follows: The ash is dissolved in  $\text{HNO}_3$  (1 in 5), insol. matter is filtered off,  $\text{AgNO}_3$  and  $\text{H}_2\text{PO}_4$  are added (10 cc. and 2.4 cc. per 100 cc. final vol., resp.), and the pink color is matched against standard  $\text{KMnO}_4$ . Mn is widely distributed in foodstuffs. Oils contain little.

FRANCES KRASNOW

**Milling and baking experiments with crossbred wheats.** W. R. JEWELL AND MARY SIMPSON. *J. Dept. Agr. Victoria* 27, 65-70(1929).—The usual milling, baking and analytical tests were made on 12 varieties of crossbred wheats grown for exptl. purposes. The majority of the flours contained less than 10.5% protein and were inferior in strength as indicated by loaf vol. Yields of flour varying from 69.75 to 75.31% were obtained.

K. D. JACOB

**The effect of cutting Garnet wheat at different stages of maturity and on consecutive dates after the occurrence of frost.** GEORGE E. DELONG. Dominion Expt. Sta., Lacombe, Alta. *Sci. Agr.* 9, 566-74(1929).—In frosted wheat, moisture is retained longer than in immature wheat and the grade is reduced. Though the protein content is high, the flour is of poor milling quality in frosted wheat. Ash content is decreased as the kernel attains maturity but the change is slight after the soft dough stage is reached.

C. R. F.

**The toxicity of wheat flour for yeast.** R. LECOURT. Thesis, Univ. Paris and Inst. Pasteur. *Ann. Brasserie* 26, 14-5, 72-7, 87-91, 102-7, 119-21, 134-7, 153-7(1927).—Hayduck's investigations (*Ibid* 11, 142, 150; 13, 179) were checked and elaborated upon. When flour is mixed with a small quantity of  $\text{H}_2\text{O}$  and immediately filtered, a clear, toxic ext. is obtained. Of all the constituents of flour, only the gluten is toxic to bakers' or brewers' yeast. The method of testing toxicity was the detn. of evolved  $\text{CO}_2$ .

from the inoculated dough held in a thermostat at 25–30°. Gluten exts. obtained by the use of acidulated  $H_2O$  (1:1000) were extremely toxic. The toxic property is definitely assocd. with the glutenin, yet the latter is readily freed from the poisonous principle by decreasing the acidity of the water. The toxin is adsorbed by the dead yeast cells, starch grains, talc, Kaolin, norit, from neutral solns. and from nitrocellulose in weakly alk. solns. It is not adsorbed by silica or albumin. The poisonous principle is very potent, only minute quantities being necessary to destroy the action of yeasts; it is comparable in a measure to toxins and diastases. Zymase is unaffected by the toxin. In the presence of sugar, yeast cells are rapidly destroyed, but the toxicity decreases with increasing titratable acidity of the soln. The rapid action of the toxin manifests itself only in the presence of a fermentable carbohydrate and appears to be a function of the sugar concn. In the absence of sugar, the poisonous action is *nil* at 2°, but at 27° there is a slight action on both bakers' and brewers' yeast. Dil. concns. of  $NaCl$ ,  $K_2SO_4$ , or  $CaCl_2$  did not greatly affect the toxicity of gluten, but all salts except  $CaCO_3$  proved toxic when present in relatively concd. solns. Brewers' yeast when grown on media other than malt did not lose its sensitivity to the wheat-flour toxin. Bakers' yeast, if cultivated on yeast or malt exts., lost, to a degree, its resistance to the toxin, but aerobic cultivation retarded this loss of resistance. Aerobic growth tended slowly to increase the resistance to toxin of brewers' yeast. Some races of yeast are less sensitive than others to the poisonous principle of the flour. C. R. FELLERS

The role of carbohydrates and proteins in the staling of bread. L. KARACSONYI. Tech. Hochschule Budapest. *Z. Untersuch. Lebensm.* 56, 479–84 (1928).—Using 12 samples of wheat bread made from flour,  $H_2O$ ,  $NaCl$  and yeast, K. detd. the amts. of  $H_2O$ -sol. and  $EtOH$ -sol. carbohydrate and protein in both freshly baked loaves and bread, which had aged for 48 hrs. Dry matter as well as  $EtOH$ -insol. glucose and protein was similarly estd. The chem. differences found between fresh and stale bread were very slight.  $H_2O$ -sol. carbohydrates increased slightly during the staling process. It could not be experimentally proved that the water of syneresis liberated from the starch gel was absorbed by the protein gel. Katz's contention (*C. A.* 9, 1808) that there is a considerable decrease in both  $H_2O$ -sol. and  $EtOH$ -insol. carbohydrates during staling is partially supported. The swelling or absorption of  $H_2O$  by the proteins shows probably that their hydration occurs. The conclusions are tentative. C. R. FELLERS

The direct determination of the chlorine ion in milk with the aid of the visual conductivity titration. H. SCHORSTEIN, G. JANDER AND O. PFUNDT. Univ. of Göttingen. *Z. angew. Chem.* 42, 335–6 (1929).—It is possible to det. the  $Cl$  ion content of milk by electrometric or conduction titrations using quinhydrone, and Pt and calomel electrodes. The chief advantage of this method is the lower time factor. Three titration curves are shown. RUSSELL C. ERB

The cryoscopic method for the detection of added water in milk. R. L. ANDREW. Govt Lab at New Zealand. *Analyst* 54, 210–6 (1929).—The lab. method employed in New Zealand for the detn. of the f. p. of milk is explained in detail and values are given, which show that, in spite of wide variations in fat and in solids-not-fat, the f. p. of unwatered milk almost invariably lies between  $-0.545^\circ$  and  $-0.565^\circ$ . The cryoscopic method for the detection of watered milk has, therefore, proved useful. W. T. H.

Investigations on the relations between the acidity and freezing point of milk. ALFRED J. PARKER AND L. S. SPACKMAN. Public Analyst's Lab. at New Zealand. *Analyst* 54, 217–23 (1929).—The f. ps. of milk samples were detd. in both fresh and adulterated samples with increasing acidities and the results show that the cryoscopic method for detg. watering in milk is reliable only when the samples are quite fresh. The value 0.20% acidity as given by the Conn. Agr. Station is criticized and the value 0.14% is suggested as being more nearly the normal acidity of fresh milk. A correction factor of  $0.003^\circ$  for each 0.01% excess acidity holds in the f. p. detn. between acidities of 0.17 and 0.60%; a value of  $0.010^\circ$  is suggested for 0.14–0.17% acidity. W. T. H.

Applications of the nitrile method. II. 1. The hydrocyanic acid binding by milk, milk sugar and milk sugar-casein mixtures. 2. The hydrocyanic acid number of milk and its analytical significance. 3. Detection of watering of milk. 4. Formaldehyde binding in milk sugar and milk sugar-casein mixtures. 5. Binding of formaldehyde and determination of formaldehyde in milk. FRITZ LIPPICH. Univ. Prague. *Z. anal. Chem.* 76, 321–35 (1929); cf. *C. A.* 23, 2393.—HCN combines with milk sufficiently to permit the application of L.'s nitrile method. There is, therefore, what can be called the "HCN no." of milk, which is a characteristic that can serve for the detection of watering in milk. The quantity of HCN taken up by milk, however, varies with the time. Thus, on treating 100 cc. of milk with 15 cc. of 0.25 N KCN soln.,

there is taken up 0.151 milli-equiv. of HCN in 1 min., 0.75 in 10 mins. and 1.155 in 1 hr. It is recommended to work at a temp. of 19°. A study of the amts. of HCN taken up by casein, milk sugar and milk itself shows certain peculiarities. At first the HCN is taken up to a greater extent by milk sugar than by milk itself, but as the digestion with KCN proceeds, the milk begins to absorb considerably more HCN than the sugar and, in fact, during a 10-min. period it absorbs more than the casein and the milk-sugar contents would indicate when measured separately, although it seems certain that only these 2 constituents take part in the reaction. It is probably due to the degree of dispersion of the colloids. To carry out the detn. of the HCN no., heat 20 cc. of 0.25 N KCN on a water bath to 19° and do the same with 100 cc. of milk. As soon as the temp. is const., add the milk as quickly as possible to the KCN soln. and count the time from this moment. After 10 mins. pour the mixt. into a soln. of 40 g. tartaric acid in 70 cc. of water, wash out the flask and connect with a condenser. Connect the condenser with a receiver contg. 50 cc. of 10% KOH. Heat carefully to boiling and conduct a stream of CO<sub>2</sub>-free air through the app. for 2.5 hrs. Then dil., add NH<sub>4</sub>OH and KI and titrate as previously described. With respect to the binding of HCHO by milk, it seems certain also that milk sugar and casein alone participate; the proposal is made to have a "formaldehyde no." as a characteristic of milk. An HCN no. of about 9 and a formaldehyde no. of about 4 indicates a mixt. of approx. 4 casein to 5 milk sugar in milk.

W. T. H.

**Cotrone cheese.** E. DE'CONNO AND M. FRATTURA. *Ann. chim. applicata* 19, 65-76 (1929).—This goat-milk cheese has been examined and submitted to a complete chem. analysis. Its characteristics are fat content 22.3-23.4%, proteins 32.5-33.5% and NaCl in the ash over 50%. This NaCl is added to the cheese.

A. W. CONTIERI

**The Schmid-Bondzynski-Ratzlaff method for the determination of fat in cheese.** B. C. VAN BALEN WALTER. *Chem. Weekblad* 26, 164(1929).—By using an extn. flask of special design, the author claims greater accuracy with this well-known method.

J. C. JURRIENS

**Scientific aspects of packaging and quick-freezing perishable flesh products.** CLARENCE BIRDSEYE. *Ind. Eng. Chem.* 21, 414(1929).—Expts. indicate that slow freezing of meats forms large ice crystals, which compress and rupture the tissues. Foods quickly frozen by direct or indirect contact with the refrigerant have the following advantages: the small ice crystals thus formed do not injure the tissues; the texture, flavor, color and odor of the product are retained; there is no shrinkage from loss of water.

N. M. NAYLOR

**The chemical change in the heat-drying of fish muscle.** I. (Japanese with English résumé.) SHOKICHI YAMAMATO AND SHIGESHI MASUDA. *J. Imp. Fish. Inst. (Tokyo)* 22, 53-5, 188-97(1926); *Biol. Abstracts* 2, 202.—Insuring freshness of fish is essential to successful drying. Moisture in the product may be limited to 14-23%. When fish muscles are dried by heating for a long time, monoamino acid N is in most cases gradually decomposed, chiefly due to the action of heat. It is advisable to keep the drying process within the limit of 30-70°, and probably best to dry as rapidly as possible at the relatively low temp. of 25-69° in order to preserve the natural flavor. From many exptl. results, it was found that during heat-drying the diamino acid N does not decrease like the monoamino acid N, but rather increases. Such a substance as "Ajinomoto," which contains a large amt. of monoamino acid, imparts a fine fresh meat flavor. The flavor of fish food may be said to accompany the presence of a fresh extractive.

H. L. D.

**Freezing storage of fruit and vegetables for retail distribution in paraffined paper containers.** M. A. JOSLYN AND W. V. CRUESS. *Univ. Calif. Fruit Products J. Am. Vinegar Ind.* 8, No. 7, 9-12; 8, No. 8, 9-12(1929).—In general the packing of fruit in sirup was found superior to the dry-pack and the sugar-pack methods. The paper "bottle" was found to be an ideal container. The freezing method has been extended to the packing of vegetables, which, when blanched and packed in brine in paper "bottles" and stored at 0-15° F., are equal to fresh even after several months' storage. J. A. K.

**Determination of oxymethylfurfural in honey and artificial honey.** J. FIEBE AND W. KORDATZKI. *Preussischen Hygiene-Inst. Landsberg. Z. Untersuch. Lebensm.* 56, 490-2(1928); cf. *C. A.* 23, 1965.—Comparative expts. on genuine and artificial invert sugar honeys were conducted by 3 methods. Troje's method (*C. A.* 20, 3753) of titration with an alk. soln. of I, Lank's method (*C. A.* 12, 1556) and detn. by pptn. with phloroglucinol were carefully tested. Only the phloroglucinol and Lank methods gave reliable results, i.e., both gave heavy ppts. and strongly reduced dil. alk. Cu solns. with artificial honeys only. Genuine honeys gave neg. results. Troje's method was distinctly unreliable in differentiating genuine from artificial honeys. The sample was

prepd. as follows for the comparative tests: A soln. of 100 g. of sample was pptd. with  $ZnCl_2 \cdot H_2O$  and  $K_4Fe(CN)_6$  and the filtered liquid thrice extd. with  $Et_2O$  in 12 hrs. The  $Et_2O$  ext. was well shaken with alk.  $Na_2SO_4$  and an equal vol. of petroleum ether, and after 24 hrs. filtered and evapd. at a low temp. The residue was extd. with 20 cc. of cold  $H_2O$  and 5 cc. of the filtered ext. used for each detn. C. R. F.

Applications of the nitrile method. III. The HCN and  $CH_2O$  numbers of sugars. 2. Their analytical significance. 3. Determinations of sugar. IV. 1. The significance of the hydrocyanic number of sugars in the analysis of sugar mixtures. 2. Determination of sugars in marmalade (LIPPICH) 7. Significance of mineral metabolism. I. Ca and P contents of some Porto Rican food materials (COOK, RIVERA) 11E. Determination of starch in grain and milling products (VON SCHEELE, SVENSSON) 28. Apparatus for drying macaroni, etc. (U. S. pat. 1,711,188) 1. Treating cannery waste (U. S. pat. 1,711,105) 14. Filter for milk or other liquids (U. S. pat. 1,710,758) 1. Penetrometer for testing the hardness of fruit, etc. (Brit. pat. 298,662) 1.

RENNES, J.: *La question du lait*. PARIS: Masson et Cie. 222 pp. F. 18. Reviewed in *Bull. soc. chim. Belg.* 37, 317(1928).

Food. FIRMA W. MASEBERG and EDUARD NEHRING. Ger. 474,633, Dec. 1, 1925—The removal of skin or peel from transported fruit is facilitated by a brief contact with concd.  $H_2SO_4$  prior to transportation. Light rubbing with water then removes the skin.

Food. OTTO STRÜBER, JR. Ger. 474,767, April 8, 1926. Dried meats are preserved by packing in powder consisting of 80 parts dry peat dust, 10 parts deciduous tree ash, 8 parts gypsum and 2 parts pepper.

Preserving milk, etc. FRANZ SEIDEL and ROMAN HELLER. Austrian 112,466, Oct. 15, 1928. Milk and other beverages are sterilized and preserved by degasifying and heating to below  $63^\circ$  and then subjecting the liquid in thin layers and *in vacuo* to elec. treatment. A magnetic field may act on the liquid during the elec. treatment.

Apparatus for cooling and aerating milk. LORENZ C. JORGENSEN. Fr. 650,049, Feb. 4, 1928.

Apparatus for pasteurizing milk in bulk. NOKMAN B. GARDINER. U. S. 1,710,771, April 30.

Treating milk with ultra-violet radiations to develop antirachitic properties. DRY MILK Co. Brit. 298,585, June 11, 1927. The intensity of the radiations and the duration of treatment are controlled to avoid the production of an unpleasant odor or taste while developing at least 75% of the producible antirachitic property. Either milk or milk powder may be treated. An app. is described.

Cheese. WM. D. RICHARDSON (to Swift & Co.). U. S. 1,711,032, April 30. Dried milk powder is mixed with whole milk to form a mixt. of approx. the moisture content desired for the finished cheese; the concd. product is coagulated.

Cheese. THE SOUTH AUSTRALIAN FARMERS' COÖPERATIVE UNION, LTD. Australia 11,258, Jan. 13, 1928. The keeping qualities and taste of cheese (Edam, Gruyere, Gouda, or Cheddar) are improved by milling, mixing with water or an alk. soln. of Na biphosphate, heating to  $120$ – $160^\circ F.$ , and then boiling in a vacuum pan, with agitator means, at  $182^\circ$  down to  $115^\circ F.$

Bakers' ovens. NICOLAS NAVROTZKY. Fr. 649,460, Feb. 2, 1928. An app. is described for the recovery of alc. produced in baking bread.

Curing meats and fish. M. M. HERIOT. Brit. 298,802, Dec. 2, 1927. An app. is described by which the material (such as hams, bacon, or fish) is treated with a brine preserving soln. and alternately subjected to vacuum and pressure.

Apparatus for drying flaked cereals. P. TURNER. Brit. 299,134, Aug. 20, 1927.

Treating cereals such as wheat with heated air and steam. J. A. HALL and W. F. C. GEORGE. Brit. 298,700, July 19, 1927. The grain is subjected for 4–10 hrs. to circulated heated air at a temp. of  $100^\circ$  or somewhat higher with which sufficient steam is mixed to cause the air to be satd. if cooled to a temp. of  $60^\circ$ . The treated grain is ground and 3% or less of the product is mixed with ordinary flour.

Fruit juice beverages. G. SCHICHT A.-G. Brit. 299,043, Oct. 21, 1927. Sterilization and clarification of fruit juice is effected by passage through sterilizing filters before concn. by evapn. at a low temp. in high vacuum to obtain a sirup, which retains the color, taste and vitamins of the original juice.

Preparations with an artificial coffee aroma. INT. NÄHRUNG -U. GENUSSMITTEL-

A.-G. Swiss 130,605 to 130,608, Sept. 16, 1926. Addns. to Swiss 128,720. Prepn.s with a coffee-like aroma are obtained by the action of furfural, acetylpropionyl, or methyl-ethylacetaldehyde on furfuryl-2-mercaptan or by the action of acetylpropionyl on hydroxymethyl-5-furfuryl-2-mercaptan.

### 13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

Italian chemical industry, 1928. BUR. OF FOREIGN AND DOMESTIC COMMERCE. *Trade Information Bull.* 577, 48 pp. E. J. C.

Mechanical handling of materials in and about the chemical plant. I. A. K. BURDITT AND W. F. SCHAPHORST. *Ind. Eng. Chem.* 21, 489-93(1929).—The application of mech.-handling equipment includes the unloading; the bulk storage of materials; the withdrawal of materials from storage; handling of materials through process; storage of finished products; and loading or shipment of products. Production and material handling can be synchronized to best advantage when the building is designed to provide this synchronization. This first article describes representative types of conveyors. G. H. VON FUCHS

Tungsten as a chemico-technical raw material. H. ALTERTHUM. *Z. angew. Chem.* 42, 275-8, 308-14(1929).—A comprehensive presentation of the importance of W in industry, its occurrence and prepn., uses (a) in the pure state for plating, surface-hardening, chemico-technical purposes, electrodes and as a catalyst; (b) in alloys with Cu, Pb, Ni, acid-resistant substances, W steel; (c) in W carbide alloys such as stellite, sintered materials or refractories like "Widia" (W carbide and Co), etc.; and (d) in tungstic acid and tungstates. A bibliography of 84 titles is included. W. C. E.

Chemical prices react to technical advances. WM. HAYNES. *Ind. Eng. Chem.* 21, 485-8(1929).—New improved mfg. processes have directed chem. prices downward. Technical advances in other fields create new markets for new chem. products, thereby having an opposite effect. Chem. prices will continue to decline as a result of successful chem. research in industrial fields. Price charts of the most important chemicals together with brief descriptions of the price movements of the last decade are given. G. H. VON FUCHS

Elements in patent law. K. D. McELROY. *Ind. Eng. Chem.* 21, 608-9(1929). Patents and procedure. FORD W. HARRIS. *Ibid* 609-11. E. J. C.

Electrical insulating papers for the manufacture of power cables. T. N. RILEY AND T. R. SCOTT. *Electrician* 102, 441-2(1929).—Impregnated paper is thus far the only practical dielectric for high voltages. The physical and elec. characteristics of such papers are reviewed; the optimum type has low bulk combined with high oil absorbency. Problems requiring further research are indicated. M. McMAHON

The prevention of ionization in impregnated paper dielectrics. S. G. BROWN AND P. A. SPORING. *Electrician* 102, 443(1929).—The effect of ionization of entrapped air upon elec. properties of a dielectric is considered. The abs. potential rather than the potential gradient is the deciding factor in detg. whether a dielectric will fail. Ionization of entrapped air is possible only when the voltage applied to electrodes exceeds min. sparking potential, approx. 300 v. in air at 1 atm. Inserting a guard strip produces a marked protective effect. Power factor-vs.-voltage curves taken with a dielectric impregnated but not evacuated serve as a reliable test. In testing a finished product a curve should be taken of a sample length of cable or a condenser placed in a vacuum. M. McMAHON

Flashpoints of solvents and plasticizers. ERNST VON MÜHLENDahl. *Farben-Ztg.* 34, 1427-9(1929).—The author lists the flash points of 110 pure solvents and plasticizers, of 7 binary and 2 ternary systems. A bibliography of the sources of the data is given. G. G. SWARD

Distillation in gas currents (LIBINSON, PAKSHVER) 2. Effect of temperature and concentration on viscosity of salt solutions (BÜCHE) 2. Importance of crystal structure imperfections in understanding the technical properties of industrial materials that are alterable (SMEKAL) 2. How does CO<sub>2</sub> behave under pressure? (KRASE, GOODMAN) 2. Thermostatic control for gas supplied to the burner of refrigerating apparatus (U. S. pat. 1,711,403) 1.

**Purification of gases.** CARL WELLER. Ger. 474,800, Oct. 9, 1926. Dust is extd. from gases by passing the gas through a plant comprising successive series of oblique tubes.

**Purification of gases.** METALLGESELLSCHAFT A.-G. Ger. 474,935, Aug. 9, 1925. Gases are led through narrow curved passages, moistened with washing liquid, to remove suspended particles and constituents sol. in the liquid, and to cool them.

**Washing gases.** CHARLES É. GOENAGA. Fr. 649,633, Feb. 24, 1928. Impurities are removed from gases by blowing them on to the surface of a suitable liquid, the emulsion produced being removed and dried for the recovery of the impurities.

**Liquefaction of gases.** RUDOLF K. E. MEWES. Ger. 472,951, July 15, 1924. A single stage method of splitting up a mixt. of gases difficult to liquify, such as air, by rectification, is described.

**Mixing gases and liquids.** PAUL OSTIER. Fr. 648,462, Feb. 6, 1928. An app. similar to a vacuum pump worked by a flow of water is used for mixing gases with liquids, e. g., treating water, wine, or alc. with  $O_3$ , or sugar juices with  $SO_2$ .

**Clarifying liquids.** MANUF. DES GLACES ET PRODUITS CHIMIQUES DE SAINT-GOBAIN. Ger. 472,948, May 29, 1925. Solid material in turbid liquids is deposited and graded by an app. having successive vats for receiving the liquid.

**Sterilizing liquids or plastic materials.** HERBERT J. KRATZER. U. S. 1,711,097, April 30. The material to be sterilized is circulated in a closed system so that it is alternately subjected to a pressure of approx. 75 lbs. per sq. in. and to a pressure less than atm. pressure; it is aerated in the portion of the app. used where it is subjected to pressure, and introduced into the reduced pressure zone in such a manner as to effect its agitation. An app. is described.

**Separation of liquids.** I. G. FARBENIND. A.-G. Fr. 649,429, Jan. 27, 1928. Liquids are continuously sep'd. by distn. and fractional condensation under ordinary, slightly raised, or reduced pressure, by treating the mixt. of vapors formed successively by washing liquids, which may be the condensed liquids themselves, the temps. of which are situated between the dew points of 2 consecutive fractions of the mixt. and the amt. of which suffices to absorb and eliminate the heat produced by the condensation.

**Separating impurities from liquids such as wax from oils by centrifuging and heating.** CYRUS H. HAPGOOD (to DeLaval Separator Co.). U. S. 1,711,315, April 30. An app. is described in which a heating medium such as steam may be used for heating the material treated out of contact with the latter.

**Evaporating liquids from solids.** HEINRICH V. DAHLEM, CARL SCHMIDT and NIKO DE KOZMITZA. Fr. 649,663, Feb. 24, 1928. Liquids are evap'd. in a vessel having a double walled conical cover, which becomes heated by the steam passing between the walls. When the contents become very concd., they are blown by steam pressure through a pipe at the base to the top of the outside of the cover and lose the remaining liquid as they descend the cover.

**Reactions between solids and liquids.** ASSOCIATION PARISIENNE POUR L'IND. CHIM. (Georges Baumé, inventor). Fr. 650,098, Aug. 8, 1927. Intimate contact between solids and liquids entering into reaction is obtained by evacuating the vessel contg. the solid, allowing the liquid to flow in and then applying pressure. Substances

such as saponin, certain soaps and animal or vegetable oils, which allow the liquid to spread into layers of a thickness of mol. order, may be added to the liquids.

Oxidations and reductions and other reactions. SIEMENS & HALSKA A.-G. Brit. 298,461, Oct. 8, 1927. Reagents in powd. form are introduced into liquids to be treated, in perforated containers; e. g., Na peroxide in a perforated metal box may be added to a soln. of Na stannite to oxidize it to stannate prior to electrolysis, or Zn solns. may be similarly oxidized before electrolysis.

Effecting chemical reactions. WILHELM KOCHMANN. Ger. 474,075, May 6, 1914. The reagents are passed through a reaction space in a uniform thin layer at a const. velocity. Reference is made to the *oxidation of NH<sub>3</sub>*, the *hydrolysis of starch*, the *production of ozone*, and to nitration, sulfonation and hydrogenation, but no example is given.

Dialysis. GIUSEPPE DONAGEMMA. Fr. 648,721, Feb. 14, 1928. An app. is described for the continuous sepn. on an industrial scale by dialysis of crystallizable substances from colloids with which they are mixed.

Sublimation. SOC. POUR L'EXPLOITATION DES PROCÉDÉS AB-DER-HALDEN. Fr. 649,974, Feb. 27, 1928. C<sub>10</sub>H<sub>8</sub> and other substances are sublimed by passing a current of air through the heated material then through cooling chambers, and back in a closed cycle.

Testing metal blocks or other materials under stress. LUDWIG HÄRTER. U. S. 1,711,347, April 30. The surface of a section of material to be tested, such as a block of metal, is dotted, parallel to the direction of the stress, by a dye, which appears in sufficient relief; the body is subjected to increasing stress, as by compression, and a photographic plate is exposed during the time of application of the stress to obtain a record of the paths of the dots.

Protective mask for use in noxious gases. ALEXANDER B. DRÄGER. U. S. 1,710,813, April 30. Structural features.

Refrigerating. CHICAGO PNEUMATIC TOOL CO. Ger. 473,414, Jan. 21, 1927. A compression machine working in a closed cycle is described in which the refrigerant, e. g., CH<sub>2</sub>Cl<sub>2</sub>, forms a vehicle for the lubricant. An inert gas may circulate with the refrigerant and the lubricant.

Refrigerating apparatus. HANS LÜTZENBURGER. Swiss 129,986, Nov. 30, 1927. Details of the arrangement of the compressor, suction and pressure pumps, evaporator and condenser.

Refrigerating machine. AKTIEN-GESELLSCHAFT DER MASCHINENFABRIKEN ESCHER WYSS & CIE. Swiss 129,987, Dec. 30, 1927. The machine has an automatic elec. regulating device.

Refrigerating machine. GEBRÜDER SULZER A.-G. Swiss 130,240, Sept. 22, 1927.

Refrigerating machine. AUDIFFREN REFRIGERATING MACHINE CO. Ger. 474,266, Mar. 7, 1924. A compression refrigerating machine has a rotary condenser and evaporator provided with radial blades to facilitate exchange of heat.

Periodically acting refrigerating machine. HUPERT HEMPEL. Ger. 473,730, Jan. 1, 1927.

Refrigerating plant. CHARLES DELAYGUE. Fr. 650,087, Aug. 5, 1927.

Refrigerating system. P. SCHLUMBOHM. Brit. 299,052, Oct. 21, 1927. Refrigerants of low vapor pressure such as water, pyridine, or octane are used in vacuum refrigerating app. having a Hg-vapor injector pump. An arrangement of app. is described.

Detection of methyl chloride in refrigerating systems, etc. GEORGE S. LOBDELL and HENRY J. KAUTH. U. S. 1,710,933, April 30. MeNO<sub>2</sub> is added to a refrigerant such as MeCl<sub>3</sub> or the like to be tested; by the reaction of the MeNO<sub>2</sub> with  $\alpha$ -naphthylamine acetate and sulfanilic acid, the mixt. is detected; this test serves to det. the presence of leakage vapors.

Method of assisting the absorption liquid in a refrigerating machine. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG. Ger. 473,834, Dec. 5, 1926. A pressure equalizing gas assists the circulation of the liquid.

Continuously acting absorption refrigerating apparatus. SIEMENS-SCHUCKERTWERKE A.-G. Brit. 298,603, Oct. 12, 1927. Liquid refrigerant is used to rectify the vapor passing from the generator. Various structural details are described.

Refrigerating system of the absorption type. PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (to Electrolux, Ltd.). Brit. 298,574-5, Oct. 11, 1927.

Refrigerators. FRIGIDAIRE CORP. Fr. 650,047, Feb. 2, 1928.

Absorption refrigerating machine. GEBRÜDER SULZER. Swiss 130,531, Sept. 22, 1927.

**Absorption refrigerating apparatus.** PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (Alvar Lenning, inventor). Ger. 472,751, May 28, 1927. Details of arrangement.

**Absorption refrigerating apparatus.** PLATEN-MUNTERS REFRIGERATING SYSTEM AKTIEBOLAG (Alvar Lenning, inventor). Ger. 473,835, July 22, 1927. Details of construction.

**Refrigerators, absorption type.** GUIDO MAIURI and RAOUL F. BOSSINI. Fr. 649,331 and 649,333, Feb. 20, 1928.

**Refrigerating apparatus of the compression type.** H. B. HULL (to Frigidaire Corp.). Brit. 299,028, Oct. 20, 1927. Structural features.

**Insulating material.** BATTERIEN-U. ELEMENTE-FAB. SYSTEM ZEILER. A.-G. Ger. 472,614, Mar. 25, 1925. Insulating material for protecting batteries, cables and the like, is prepd. by sapon. montan wax, ozocerite and bituminous material with alkali.

**Electrical insulating material comprising rubber.** A. R. KEMP and WESTERN ELECTRIC CO. Brit. 298,694, July 18, 1927. A process is described for compounding rubber compns. of different S content (one of which may contain 5% and the other 20% S) to produce an insulating material, which has mech. properties similar to the product described in Brit. 246,663 but which may have approx. the same thermoplastic properties as gutta percha and which has elec. properties rendering it more suitable for use in submarine cables than the product described in Brit. 246,663.

## 14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

**Factors contributing to quality of public water supplies.** H. E. JORDAN. *Ind. Eng. Chem.* 21, 152-6(1929).—In the abstract of this title in C. A. 23, 1703 the first word in the 4th line should read "service" and the first figure in the last line should be "22"

E. B.

**The new water supply system of Parkersburg, West Virginia.** M. G. MANSFIELD AND F. C. FOOTE. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 85-101(1928).—A history of the sources of water supply from about 1884 is given. A referendum vote in 1925 showed that a well supply was preferred to the filtered Ohio River water. The new water supply system consists of 12 drilled wells (Layne patent gravel wall) 51 to 61 ft. deep, 38 in. in diam. with an 18-in. inside pipe. A detailed description of the wells and the method of sinking is given. The 12 wells yielded over 6 m. g. d. Free CO<sub>2</sub> in the untreated water varied from 20 to 65 p. p. m. and Fe from 0.1 to 3.4 p. p. m. The CO<sub>2</sub>-removal plant is described in detail. Provision is made for Fe removal if necessary in the future. Steam can be used in place of electricity in an emergency. Total cost of the plant will approx. \$292,000.

C. H. BADGER

**The problem of water supply in Cochin China.** A. MACHIN. *L'Eau* 22, 19-22 (1929).—Sanitary engineering data are discussed.

C. R. FELLERS

**Pregel water supply of Königsberg.** R. BRÜCHE AND G. SATTLER. *Gas u. Wasserfach* 72, 237-43, 263-7, 287-91(1929).—Water from the Pregel River, after a preliminary sedimentation, is treated simultaneously with alum and chlorine to clarify it and to remove color; it is then passed through a rapid filter and again chlorinated to destroy bacteria. The treated water is satisfactory from the bacteriol. and chem. viewpoints, being practically colorless, tasteless and without after-taste.

R. W. RYAN

**Underground water—its formation and modes of appearance.** F. RÖHRER. Univ. Heidelberg. *Gas u. Wasserfach* 72, 174-80, 199-205(1929).—Theories as to the formation of ground water are critically reviewed with the conclusion that the larger part of the ground water is due to infiltration. Water-bearing strata and the formation and characteristics of springs are also discussed in detail and applications to water supply noted.

R. W. RYAN

**The graphical representation of the chemical constituents of mineral waters.** Z. DALMADY. *Z. ges. physik. Therap.* 34, 144-7(1927); *Wasser u. Abwasser*, 25, 101.—The ions and cations are graphically located on a circular diagram to show at a glance their true relationships.

C. R. FELLERS

**The thermal waters of Vichy and their important physical and chemical properties.** MANCRAU. *Zentr. ges. Hyg.* 16, 690-1(1928); *Wasser u. Abwasser* 25, 103.—Of the numerous springs of the Vichy basins only 14 are utilized. Of these 5 are natural and 9 are bored. The flow of these 14 springs per 24 hrs. is approx. 700,000 l. The water is very sparkling and alk. The underlying collecting basins lie in tertiary strata, the

layers, direction and cleavages of which are discussed. Typical analysis giving sp. gr., pH, cond., gas content, minerals and radio-activity is tabulated. C. R. FELLERS

The Landecker (thermal) springs in the light of the latest balneological investigations. LACHMANN. *Z. wiss. Bäderkde* 2, 611-8(1928); *Wasser u. Abwasser* 25, 104.—These thermal waters act on all the body functions, particularly on the secretive and nervous processes. Because of the content of Rn, these waters are excellent in the treatment of rheumatism and diseases of the joints. The S compds. such as  $H_2S$ , colloidal S and polythionic acids, penetrate the skin and favorably influence the body metabolism and joint action. C. R. FELLERS

Alkaline sulfur waters. A. ASTRUC. *Bull. soc. sci. méd. biol. Montpellier* 8, 483-506(1927); *Wasser u. Abwasser* 25, 102.—In the French Pyrenees many waters contain S in forms other than oxidized S, such as  $H_2S$ , sulfides, free S and acids. Silicic acid and certain S-algae often occur together in hot springs. Remedial treatment measures are of little avail in these waters. C. R. FELLERS

The determination of sulfate in natural waters and in soil extracts. B. SAPROMETOV. *Bull. Univ. Asie Centrale*. Tashkent, Russia; *Wasser u. Abwasser* 25, 40 (1928).—A comparison was made of the gravimetric pptn. as  $BaSO_4$ , of the benzidine and the titrimetric I methods. For routine work sufficient accuracy was given by the modified rapid benzidine method of Raschig (cf. *C. A.* 21, 3242) to recommend it. C. R. F.

The stratification of oxygen in lakes. L. L. ROSSOLIMO. *Biol. Station, Kossino. Arch. Hydrobiol.* 19, 731-41(1928). G. SCHWOCH

Dependence of oxidizability on the fluctuation of the ground-water level. BR. PUCHOWSKI. *Zentr. ges. Hyg. Grenz.* 17, 801(1928); *Wasser u. Abwasser* 25, 113.—No correlation could be observed in 4 wells between the oxidizability of the water and the water level in the wells. C. R. FELLERS

Water purification problems in Ohio. THOMAS R. LATHROP. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 12-21(1928).—The pollution of Lake Erie and the Ohio and Mahoning Rivers, the purification methods employed at the different plants, odors due to chlorophenols and depleted O, recarbonization of treated waters, trouble with algae clogging filters, Fe removal, incrustation of Mn on sand in filters, and the municipal softening of water supplies are briefly discussed. C. H. BADGER

Aeration in the purification of water. N. T. VRATCH. *Can. Eng.* 56, 430(1929).—Aerator devices in common use are of four general classes: (1) air-lift pumps, (2) injector aerators, (3) gravity aerators, (4) fountains. To satisfy most general purposes, whether it be to remove  $CO_2$ , odors, or iron and manganese, aeration should be carried through until the water is satd. with  $O_2$ . E. HURWITZ

Purification problems of the Williamson Water Works. PAUL C. LAUX. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 123-8(1928).—The main intake consists of a concrete pit in the Tug River filled with gravel and sand, in which are located 10 infiltration wells 10 ft. deep and 2 ft. in diam. It is subject to pollution from the city and from coal mines. The water is pumped to the mixing tank, where alum is added at the entrance and lime at the outlet by dry-feed machines. It flows to 2 sedimentation basins, capacity 270,000 gals., and then to 4 filters each 176 sq. ft. in area, capacity 500,000 gals. per 24 hrs. The plant is operated intermittently every 12 hrs. The count on the applied water is sometimes higher than on the raw water in hot weather; gas forms in the filters. It is suspected this gas is due to bacterial decompn. of org. matter in the settling basins while they are idle. Although 1 p. p. m. Cl is added, 10-cc. portions of water show gas after 48 hrs., but none after 24 hrs. and no confirmatory tests. Fine coal dust in the water forms a crust with the sand on the filters, which holds back the wash water and prevents gas escaping. Raking has corrected this trouble. Prechlorination has apparently not been successful in eliminating gas formation but has improved plant conditions. C. H. BADGER

The possibilities of Clenzal in the purification of water in country homes. - ALFREDO PIO DE RODA. *Univ. of the Philippines. J. Philippine Is. Med. Assoc.* 9, 1-4(1929). - Clenzal is uniformly effective in reducing the bacterial count and in killing *B. coli* in water artificially inoculated with it. FRANCES KRASNOW

Laboratory control of filter plants. GERRITT S. BUCHANON. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 63-70(1928).—The quality of well water in western Penna. is unsatisfactory; therefore surface water supplies must be treated and used. The dividing line between a hard and a soft water in Penna. is about 100 p. p. m. hardness. A general review and discussion of rapid sand filtration, chem. and phys. control tests, hardness, corrosion and algae are given. C. H. BADGER

Experimental filtration plant, Ottawa. ANON. *Can. Eng.* 56, 359(1929).—An

experimental plant to det. the best method of treatment of the Ottawa River water has been built on Lemieux Island. The capacity of the plant is 48,000 gal. per day. Detailed description of the general plan and operation of the plant is given. E. H.

**Water filtration plant at Picton, Ont.** W. TARR. *Can. Eng.* 56, 465(1929).—The water supply of Picton, Ont., has been improved by the addition to the old system of two pressure filters, 8 ft. in diam. by 20 ft. long, with one 300-gal.-per-min. motor-driven pump, one 600-gal.-per-min. gasoline-engine-driven pump and a chlorinating unit. Detailed descriptions with drawings are given in the article. E. HURWITZ

**Deep sand-rapid filters.** A. GRAUMANN. *Pumpen u. Brunnenbau Bohrentechnik* 1928, 397-9; *Wasser u. Abwasser* 25, 127.—The operation and cleaning of the "Bollmann-Schnellfilter" are described. C. R. FELLERS

**Sterilization of new water mains.** E. C. SULLIVAN. *Can. Eng.* 56, 371(1929).—Sterilization of newly laid water mains is imperative. It can be accomplished with either liquid Cl or  $\text{CaOCl}_2$  or  $\text{NaOCl}$ , care being taken to assure high residual Cl. E. HURWITZ

**The history of the chlorination of drinking water.** SPITTA. *Reichs-Gesundheitsblatt* 33, 533-5(1928); *Wasser u. Abwasser* 25, 120.—A critical review of the development of chlorination in Germany for the past 35 yrs. Recent developments in American water treatment are largely ignored. C. R. FELLERS

**Chlorination of water. II.** L. W. HAASE. *Preuss. Land. für Wasser, Boden u. Luft hygiene. Gas u. Wasserfach* 72, 217-22(1929); cf. *C. A.* 22, 2421.—Chlorination of water for  $\frac{1}{2}$  to 1 hr. reduces the content of org. substances, especially humins, which give the water a yellow color, and also facilitates the later removal of iron, which is difficult to remove in untreated waters contg. humins. Both hard and soft waters become more acid, with a further increase in acidity on dechlorination. The water may become sufficiently acid to cause active corrosion unless it is treated in a deacidifier. Org. substances in sewage can only be slightly destroyed by intensive chlorination. R. W. RYAN

**A new formula of the reagent for the detection of nitrites in water.** STÉPHANE VERGNOUX. *Bull. sci. pharmacol.* 36, 146-7(1929).—Dissolve 2 g. neutral red in 18 cc. of  $\text{H}_2\text{O}$ , filter, cool and add 80 g.  $\text{H}_2\text{SO}_4$ . Use 100-150 cc. of the  $\text{H}_2\text{O}$  to be tested, and add 5 drops of the reagent. After stirring, a blue color appears if more than one mg. of N in the form of  $\text{HNO}_2$  is present. A. E. MEYER

**A rapid method for estimation of the total hardness by the separate estimation of the lime and magnesia hardness.** KURT V. LUCK AND HANS J. MEYER. *Z. angew. Chem.* 41, 1281-4(1928).—After testing the method of Berg (cf. *C. A.* 21, 2449) a rapid method for sep. detn. of the Ca and Mg hardness is outlined as follows: Precipitate Ca as the oxalate and titrate the ppt. with  $\text{N}/28 \text{ KMnO}_4$ . To the cooled filtrate carefully add 2 cc. of 2% alc. 8-hydroxyquinoline on the surface of the filtrate. After 5 mins. heat the soln. to boiling. If the yellow color vanishes, add more of the soln. until the liquid is definitely colored yellow. After boiling for a short time, allow to cool and stand for about an hour. Filter the ppt. Wash the beaker with 2.5% ammonia water. After washing 3 times on the filter with ammonia water, dissolve in 8-10% HCl in the original beaker. Add 2 or 3 drops of aq. indigo-carmin soln. to the HCl soln. in a stoppered Erlenmeyer flask. Titrate the blue liquid with bromate-bromide soln. ( $\text{N}/14$ ) to a yellow color. Add 2-3 cc. of 20% KI soln. and, using starch as an indicator, titrate the excess of bromate soln. with standard thiosulfate ( $\text{N}/140$ ). If 50 cc. of water is used, the number of cc. of bromate-bromide soln. used gives the Mg hardness. Satisfactory results are obtained by this method; 6 detns. of lime and magnesia hardness can be made in 1.5 hrs. EDWARD BARTOW

**Bacterial after-growths in water-distribution systems.** JOHN R. BAYLIS. *Trans. Am. Soc. Munic. Improvements* 34, 265-6(1928).—"There is no need of being alarmed at bacterial aftergrowth where it is known that pollution cannot gain entrance to the supply." A table shows the summarized records, for 1 yr., of the bacteria in the water supply of a large city. W. H. BOYNTON

**Bacterium coli in iced and uniced samples of water.** GAYFREE ELLISON, H. W. HACKLER AND W. ALFRED BUICE. *J. Am. Water Works Assoc.* 21, 528-30(1929).—See *C. A.* 23, 1974. E. C. M.

**The iodine content of tap-waters in goitrous districts.** G. H. BECKWITH. *Zentr. ges. Hyg.* 17, 878(1928); *Wasser u. Abwasser* 25, 113; cf. *C. A.* 22, 2629.—The I content of a no. of water supplies from goitrous districts in the U. S. was detd. The following amts. were found (p. p. b.): Chicago, Lake Michigan, 0.13; Litchfield, Ill., 0.17; Peru, Ill., hard ground water 0.31; Peoria, Ill., deep well, 0.15; LaSalle, Ill., deep well, 18.00;

E. St. Louis, Mississippi River, 0.29; Springfield, Ill., 50-52; Duluth, Minn., 0.014; Grantsville, Utah, 1.33. C. R. FELLERS

The "goiter-spring" in Hallstatt. FRIEDRICH MORTON. Botan. Station, Hallstatt. *Arch. Hydrobiol.* 19, 742-3(1928).—The water of the so-called "goiter-spring" in Hallstatt contains in addn. to small amts. of Ca and Mg. carbonate, phosphate and sulfate, 0.00025 mg. I as iodide, 0.00031 mg. I as iodate, 0.00012 mg. I organically bound and 0.0125 mg. F per l. Nitrite and nitrate were detected. The sediment contained a relatively large amt. of Mn. G. SCHWOCH

The use of lime in water treatment. PAUL C. LAUK. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 109-18(1928).—The value of lime in waterworks operation depends on its CaO content. Smaller plants can more easily use hydrated lime, while larger plants will economize on the use of quicklime. Roughly, the dividing line is a consumption of 100 tons. Since lime tends to settle out of suspension, dry-feed machines are more satisfactory than soln.-feed machines. The feed line for milk of lime should be large, straight and short as possible. In case of longer lines, curves, horizontal flow, etc., rubber hose should be used since lime will tend to stick to any metal surface. C. H. BADGER

Zeolite softening plant at Sewickley, Pa. D. E. DAVIS. *W. Va. Univ. Coll. of Eng. Tech. Bull.* 2, 71-7(1928).—The 2,000,000-gal. plant supplies about 5000 people. The water is taken from a crib buried in a gravel bed in the Ohio River. The clear water is sterile and about twice as hard as the river water. A typical analysis is given. An 18-in. suction line laid in a concrete tunnel connects the supply to a low service well. It is pumped to an equalizing basin. The water passes to four 500,000-gal. open concrete tubs having a false bottom arrangement of cast-bronze umbrella strainers spaced on 6-in. centers surmounted by 18 in. of graded gravel and 30 in. of sand. Greensand (glauconite) is used in 3 beds and quartz filter sand in the 4th. Filtration is downward at the rate of 2 gals. per sq. ft. per min. Brine soln. for regeneration, which takes 0.5 hr., is pumped to the top of the beds. Washing is upward at a max. rate of 15 gals. per min. Each bed delivers water of 0 hardness for 4.5 hrs., water of increasing hardness for 2 hrs. and completely hard water for 0.5 hr. The quartz sand filter furnishes wash water and filtered unsoftened water to make the final product 60 p. p. m. hardness. There are 3 clear wells under the filters, resp. used for hard, soft and mixed waters. The arrangement of the plant is described. The contract cost is \$158,659. A zeolite plant is particularly adapted to clear waters contg. relatively high  $\text{SO}_4$ ; the advantages are simpler storage and handling of salt over lime and soda, greater compactness, definite routine scheduling, and max. flexibility in operating methods. C. H. BADGER

The use of chemically prepared feed-water for high-pressure boilers. A. SPLITTGERBER. *Wärme* 51, 733-9(1928); *Wasser u. Abwasser* 25, 207. C. R. FELLERS

The classification and evaluation of boiler-feed water. R. STUMPFER. *Wärme* 51, 717(1928); *Wasser u. Abwasser* 25, 207.—Detns. of Ca, Mg,  $\text{HCO}_3$  and total hardness of boiler-feed waters give important data on scale formation in boilers and aid greatly in evaluating a water for steam generation. C. R. FELLERS

The influence of magnesium content on the hardness of boiler-feed waters. P. HERMANN. *Wärme* 51, 755-7(1928); *Wasser u. Abwasser* 25, 207.—Mg in water cannot be removed by chem. means. Large amts. of Mg cause scale formation. C. R. F.

New boiler-scale preventive. E. HERMS. *Wärme & Kälte Tech.* 30, 1-4(1928); *J. Am. Water Works Assoc.* 20, 442(1928).—H. describes the effect and mode of the use of the patented solid compd. "Hydrotor," alleged to dissolve old boiler scale and to prevent the formation of new. ERNEST W. THIELE

A review of sewage treatment. H. BACH. *Gesundh.-Ing.* 52, 241-3(1929).—In the past few years much time has been given to the question of two-storied treatment plants vs. sep. sludge digestion. Either process will give a well-digested sludge. It is difficult to form a final opinion on the relative merits of the two. Local conditions will play an important role in the selection of the best process. Sewage sludges are of considerable importance as fertilizers. The activated-sludge process is in great favor today. Several modifications of this process are mentioned. Only slight treatment of industrial sewage has been effected. WAYNE L. DENMAN

Theory and practice in the sewage profession. H. KESSENER. *Gesundh.-Ing.* 52, 248-50(1929).—In sewage treatment complicated and expensive installations such as the activated-sludge process are frequently encountered. the other hand, simple, cheap and well-designed plants often give excellent results. Poor construction does not result in any saving as inferior results are obtained. The designing of a plant should be made by competent consulting engineers, who are able to coordinate the improvements

of pure science with the operation of actual processes, which have been found to work well.

**Ballarat sewerage system.** A. FARRAR. *Australian Municipal Officers' J.* 1928, 11-7; U. S. Bur. Public Health Eng. Abstracts E-637a, 57-8.—A sep. sludge-digestion plant has been built for the greater city of Ballarat, Victoria. The plant consists essentially of 1.5-in. bar screen, 3 grit chambers (40 ft. long), Venturi meter, primary sedimentation tank (50 × 50 ft.) with sloping sides and rectangular sub-sump from which fresh solids are discharged as frequently as necessary to keep material fresh, automatic siphon, sprinkling filter beds (5'6" deep), secondary sedimentation tank used only when effluent is turbid, and 3 sep. sludge-digestion tanks (9 more planned) 25 ft. sq. and sludge drying beds 30 × 16 ft. The no. of sludge beds will be 12. Supernatant liquid of digestion tanks is discharged on trickling filters. Up to the present the effluent from the filter bed, as well as the sludge, has been highly satisfactory. Chem. analyses show that the available O in the effluent is from 4 to 6 times greater than that of the water of the town supply, and that the effluent delivered to the creek is better than is required by the British Standard for effluents. Analyses of the water in the creek above and below the plant show that the water below the point of entry is much improved when compared with that above it. O absorption in 4 hrs. of crude sewage is 5.3 grains per 100,000; of the effluent, 0.33. The sludge contains 90% water, and has a fertilizer value of £3/10/— per ton.

WAYNE L. DENMAN

H. L. D.

**Sewage and sewage purification.** REICHEL. *Deut. Korrespondenz Gesundh. u. Sozialvers.* 1928; *Wasser u. Abwasser* 25, 210.—History, development and operation of modern German sewage works are discussed.

C. R. FELLERS

**Experiences in aerating sewage.** W. H. MAKEPEACE. *Can. Eng.* 56, 379(1929); cf. C. A. 23, 1456.—Avoidance of short circuiting and thorough mixing are vital to the efficient operation of aeration tanks. Partial pre-aeration is suggested to remove load from bacteria beds.

E. HURWITZ

**Systems of sewage aeration.** GEORGE B. GASCOIGNE. *Trans. Am. Soc. Munic. Improvements* 34, 201-9(1928).—The paper deals with the activated-sludge process of sewage treatment and particularly with "the various systems of sewage aeration now used or seriously contemplated for use, either abroad or in this country." Three classes of aeration are given: (1) aeration by air diffusion; (2) surface aeration; and (3) combined aeration. Operating data in full-sized units are needed.

W. H. BOYNTON

**New sewage treatment works of Manasquan, N. J.** LOUIS L. TRIBUS. *Proc. Am. Soc. Munic. Improvements* 34, 211-8(1928).—The plant provides a single-compartment chamber having two screens arranged for alternate hoisting, later replaced by a rigid sloping bar screen, and a circular deep pumping station divided into two compartments, one dry for the pumps, the other wet for the roughly screened sewage. The sewage is pumped through a cast-iron system into one or all of four sedimentation tanks, settled and passed over weirs into a tank. An automatic recording gage registers the flow. The cast-iron outfall to the ocean is of universal type with a double outlet to partially discount choking. Bacterial purity was secondary to the avoidance of nuisance in the design and operation of this plant.

W. H. BOYNTON

**The oxidation of sewage when "hard" and "soft" waters are the carriers.** J. E. PURVIS. *J. Roy. Sanit. Inst.* 49, 587(1929).—The permanganate method for O consumed was used to det. the rate of oxidation of sewage. Oxidation was performed by aerating the sewage for several hrs. The rate of oxidation was less the larger the inorg. salt content of the sewage. This factor should be considered in the design of activated-sludge plants.

A. L. E.

**Determination of solid material deposited from sewage.** H. VAN DER ZEE. *Gesundh.-Ing.* 52, 243-6(1929).—The usual method of detg. the amt. of deposited material by means of glass sedimentation vessels is inaccurate and yields values, which after concn. of the sewage, are more or less in error. Thick sewage shows greater differences. The error of observation is caused by the packing of the already deposited sludge produced during the detn. The extent of this deposition is detd. by the shape of the vessels and by the nature of the sludge. Gravimetric detns. seem to be more accurate.

W. L. D.

**Digestion of fine screenings.** WILLEM RUDOLFS. *Proc. Am. Soc. Munic. Improvements* 34, 161-71(1928).—Results are given of digestion on a semi-plant scale of fine screenings, for a half-yr. period. Solids were reduced by 61% and the volatile matter by 66.8%. Decompn. of nitrogenous substances was 59.5% and of fatty substances 56%. The digested material dried readily and was spadeable in 3-4 days. Pressing of the material 2-5 hrs. yielded a cake contg. 66-69% moisture. The digested sludge was black and had no odor other than the ordinary gas odor. The relation be-

tween C:N in sewage solids varies from 6:1 to 13:1, which on the dry basis is 3.5-4% N, and 25-30% C. In the fine screenings the N figure is lower and the C figure higher.

W. H. BOYNTON

**Large-scale experimental and demonstration plant for the digestion of sewage screenings at Milwaukee, Wisconsin.** DARWIN W. TOWNSEND. *Proc. Am. Soc. Munic. Improvements* 34, 173-99(1928).—Basic considerations affecting the design of the plant, the digestion compartments, gasometer and gas metering equipment, facilities for charging tank compartments with screenings, glass-covered screenings, sludge beds, and the housing structure for tanks and control equipment are emphasized. A brief discussion is included.

W. H. BOYNTON

**The efficiency of settling tanks.** M. B. TARK. *Trans. Am. Soc. Munic. Improvements* 34, 225-36(1928).—Settling tanks are divided into 3 classes: (1) primary tanks, (2) final tanks for the effluent from sprinkling filters, and (3) final tanks for the effluent from activated-sludge plants. The essential features of design for continuous flow tanks are: (1) means for decreasing the velocity of flow so that the solids can settle out, (2) a zone of quietness where the settled solids can accumulate, and (3) means of removing the accumulated solids or sludge. For highest efficiency the flow should be distributed equally between the several tanks in a plant and uniformly across the section of each individual tank. The removal of the settled sludge also affects the efficiency of a settling tank. Different means of sludge removal are mentioned. A well-designed settling tank will remove 60-75% of the suspended solids. A table shows the efficiency of various tanks in the reduction of suspended solids in several New Jersey plants. Discussion brought out the factors controlling the settling capacity or ability of a continuous flow tank to produce an effluent of predetd. acceptable standard: (1) period of mixed liquor aeration before settling, (2) % of solids concn. in the liquor—a factor dependent upon the vol. of activated sludge maintained in circulation, (3) the characteristics of the sewage flow curve, and (4) the effectiveness of continuous settled and concd. sludge removal from a tank bottom particularly regarding minimizing the disturbing effect of mech. sludge-removing app. Also curves are shown, which indicate graphically the effect upon settling rates and settled-solids concn., due to various % of increase in solids content (on the dry basis) in mixed liquors. Settled sludge should be removed as speedily as possible to minimize the agitation. The sludge should be removed in as fresh a condition as possible, tanks should be provided with skimming devices and the sludge should be removed from the tank with as little moisture as possible.

W. H. BOYNTON

**Sewage purification in industrial plants.** A. PRITZKOW. *Werksleiter* 1928, 256-60; *Wasser u. Abwasser* 25, 58.—General description of well-known disposal systems.

C. R. FELLERS

**Sewage management and dry-sludge removal in Breslau.** TRAUER. *Städtereinigung* 1928, 278-9; *Wasser u. Abwasser* 25, 58.—An address discussing in detail the sewage fields, sewage-irrigated meadows and stone and rubble filters used in the Breslau disposal works.

C. R. FELLERS

**Activated sludge: its production, composition and value as a fertilizer.** O. J. NOERR. *Zentr. Bakt.* II, 73, 419(1928); *Wasser u. Abwasser* 25, 126.—Approx. 20% of the total N is recovered in the sludge. Imhoff-tank residue contained only 4% of the original N. Field and pot expts. showed excellent utilization by plants of the N in activated sludge. Analysis of dried sludge gave N, 4.7-6.5% and  $P_2O_5$ , 2.3-4%. The value assigned the dried sludge was \$25 per 1000 kg. The material is particularly adapted for meadow fertilization.

C. R. FELLERS

**An activated-sludge system of sewage disposal (followed by rapid sand filtration) for Grand Cañon National Park.** M. R. TILLOTSON. *Trans. Am. Soc. Munic. Improvements* 34, 253-6(1928).—All water used at the hotels and residences in the National Park is delivered by tank car. The activated-sludge system was adopted for sewage disposal due to the following factors: (1) the degree of purification required in order that re-use might be had of the effluent, (2) the lack of natural filtration beds, (3) the lack of necessity of de-watering sludge, (4) the degree to which control of the character of effluent might be had, and (5) coöperation from the railroad by furnishing power and operating labor. Operating results have been satisfactory and economically profitable.

W. H. BOYNTON

**Various methods of sewage disposal.** E. A. FAWCETT. *Can. Eng.* 56, 437(1929).—A careful study of conditions peculiar to a given area should be made before decision on the type of sewage treatment to be used is made. The principal methods of sewage treatment where the outfall is in the sea or in the tidal estuary are by discharging sewage (a) without treatment, (b) after screening, (c) after treatment in sedimentation tanks, (d) after sedimentation followed by filtration. Where the outfall is into a non-tidal river,

stream or other fresh-water body, the principal methods are by discharging sewage after treatment by (a) irrigation, (b) screening followed by irrigation, (c) sedimentation, (d) sedimentation filters and humus tanks, (e) activated sludge without filtration or irrigation, (f) activated sludge followed by filtration with or without irrigation. E. H.

**Continued study of gas collection in sewage-disposal plants.** JERRY DONOHUE. *Trans. Am. Soc. Munic. Improvements* 34, 219-24(1928); cf. C. A. 22, 1642.—The sewage-disposal plant at Antigo, Wisconsin, is a sep. sludge-digestion plant consisting of a screen and grit chamber, a clarifier or sedimentation tank, a sludge-digestion tank, a sludge-drying bed and a trickling filter unit. Operation during the past year demonstrates that the sep.-sludge-digestion type of plant utilizing mech. equipment, in both digester and clarifier, offers some advantages in small plant design for overcoming some of the difficulties usually encountered. The fresh sludge at the Antigo plant has 97.8% moisture and the digested sludge 98.9% moisture. The gas contains 58%  $\text{CH}_4$  and has a B. t. u. value of 645 per cu. ft., which is equiv. to  $7\frac{1}{2}$  tons (6818 kg.) of coal per thousand population.

**Home sewage disposal.** O. MOHR. *Stadt. Tiefbau* 19, 232-3, 308-12, 361-4 (1928); *Wasser u. Abwasser* 25, 219.—The transportable OMS fresh-water type of disposal plant with mech. cleaning devices is advocated where sewers are not available.

W. H. BOYNTON  
C. R. FELLERS

**A study of factors affecting the efficiency and design of farm septic tanks.** E. W. LEHMANN, R. C. KELLEHER AND A. M. BUSWELL. *Ill. State Water Survey Bull. No. 27*, 45 pp.; cf. C. A. 22, 3250.—Inasmuch as the flow of sewage per person from farm homes is subject to wide variation, the tank should be so designed as to make an av. allowance for sewage flow of 18-25 gals. per person per day depending upon the size of the family. Ordinarily it is not practical to build a tank smaller than the size required for 7 people. In a single-chamber tank a 72-hr. retention period should be provided. In a two-chamber tank a 72-hr. retention period should be provided in the 1st chamber and an additional retention period of 36 hrs. in the 2nd chamber (capacities being in the ratio of 2 to 1, or a total retention period of 108 hrs.). When properly designed, the two-chamber tank is more efficient than the one-chamber tank, particularly if the two-chamber tank is provided with 50% larger capacity. Recommendations for the design of simple farm septic tanks are given in detail.

J. A. KENNEDY

**Disposal of septic-tank effluent (at Dacca) by dilution, irrigation and digestion.** F. C. GRIFFIN. *Inst. Civil Eng., Selected Eng. Papers*, No. 65, 13 pp.(1928).—A general description of the disposal of sewage at Dacca is given.

B. C. A.

**Proof of water pollution by a simple method.** CH. GAUSSEN. *Zentr. ges. Hyg.* 18, 394(1928); *Wasser u. Abwasser* 25, 213; cf. C. A. 22, 3007.—On the basis of the observation that most pathogenic bacteria to be found in water not only form indole from peptone solns. but decolorize toluidine blue, G. uses this combination of tests to detect pollution of water. The data and conclusions are not entirely convincing.

C. R. FELLERS

**Pollution in the Monongahela River basin and its effect on public water supplies.** L. V. CARPENTER. *W. Va. Univ. Coll. of Eng. Tech. Bull. No. 2*, 27-38(1928).—Above Morgantown, W. Va., the greatest single waste is acid water from coal mines. Tabulations show the relation between gals. of acid water per acre per day of coal exhausted and % of rainfall, and between acidity and  $p_H$  values for 6 drift mines in Monongahela County. The acidity varied from 89.2 to 1300.0 grains per gal. and the  $p_H$  value from 2.0 to 3.1. An analysis of 1 of the mine waters is given. A comparison between low  $p_H$  value and low bacteria count at  $37^\circ$  is shown for 3 sampling stations located near Morgantown. Several sterile samples adjusted to  $p_H$  7.2 with lime showed bacteria at  $37^\circ$  after standing 24 hrs. and gas formation but no *B. coli* after 48 hrs., proving bacterial growth had only been inhibited.

C. H. BADGER

**The treatment of city wastes by the Beccari closed-vessel method.** JEAN BORDAS. *Station recherches agron. d'Avignon. Bull. soc. encour. ind. natl.* 128, 170-2(1929).—City waste freed from glass, tin, wood, rags and paper was filled into closed chambers of 20 cu. m. capacity. Dung was treated in smaller chambers of 5 cu. m. capacity. Fermentation and decompn. of org. matter proceed slowly with evolution of  $\text{CO}_2$ ,  $\text{NH}_3$ ,  $\text{PH}_3$ ,  $\text{CH}_4$ ,  $\text{H}_2\text{S}$  and  $\text{H}_2\text{O}$  vapor, which pass out through a chimney.  $\text{NH}_3$  is fixed and recovered in this chimney by means of argillaceous earth with  $\text{FeSO}_4$  or acid Ca phosphate. The temp. obtained is  $70-75^\circ$ . Since denitrification cannot take place at this elevated temp., there should be full conservation of N. It required 40 days for the city waste and 60 days for the dung completely to ferment and to become deodorized by the Beccari process. Night soil fermented in piles in the open air gave an analysis as follows. total N 0.45%,  $\text{P}_2\text{O}_5$  0.59% and  $\text{K}_2\text{O}$  0.52%. Night soil treated by the Bec-

carb process gave an alk. reaction and contained 0.83% N, 0.63%  $P_2O_5$  and 0.72%  $K_2O$ . A notable conservation of N is indicated by the use of the process. C. R. FELLERS

The waste plant for the town of Tours (France). A. JOULOT. *Chaleur et ind.* 10, 113-8(1929).—The plant for destroying town waste, recovery of by-products and generating power is described. The ashes are used in working up for fertilizer; they have the compn.  $SiO_2$  56.7,  $Al_2O_3$  +  $Fe_2O_3$  19.5,  $CaO$  9.6,  $MgO$  1.5,  $SO_2$  3.5,  $P_2O_5$  1.3,  $K_2O$  +  $Na_2O$  2.1%. The clinkers have the compn.  $SiO_2$  46.0,  $Al_2O_3$  16.6,  $Fe_2O_3$  8.6,  $MnO_2$  0.4,  $CaO$  21.0,  $MgO$  2.1,  $K_2O$  0.4,  $Na_2O$  3.2 with a fusion point of  $1200^\circ$  and in brick form fractures at 130 kg./cm.<sup>2</sup>. S. L. B. ETHERTON

Waste disposal—a description of the Pennsylvania study. E. G. BOYER. *Am. Gas Assoc. Monthly* 11, 201-4(1929).—This is a report on the extension of the "Pennsylvania Plan" of waste disposal by the Penna. Gas Assoc. in cooperation with the Penna. Sanitary Water Board to include effluents from gas plants. A. S. CARTER

Phenol recovery and treatment works of the Hamilton Coke and Iron Company. B. F. HATCH. *Ind. Eng. Chem.* 21, 431-3(1929).—Inert gas satd. with steam is passed in a closed cycle round and round through the hot, partially distd.  $NH_3$  liquor. At 1 point in the gas cycle there is placed a scrubbing section contg. hot  $NaOH$  soln. The phenol passes from the  $NH_3$  liquor into the steam and gas mixt. by virtue of its vapor pressure; in the caustic section it is converted into Na phenolate, which by reason of its much lower vapor pressure, remains in the caustic soln. Since the  $NH_3$  liquor and the caustic soln. are both held at or immediately below their b. p., and since the tower and piping are covered with insulating material, there are virtually no heat losses. The phys. equipment consists of a steel tower 7 ft. in diam. and 95 ft. high, a small blower, 4 small liquor pumps, 2 storage tanks and the necessary piping. The operation temps. are automatically controlled. This process can be used at any coke plant which is located on a stream or body of water of sufficient size to afford the necessary diln. for the small amt. of phenol contained in the resultant waste. The efficiency of phenol removal is high, the operation of the works is simple, the ground space required is small, the costs of operation appear to be attractive; and since this process is essentially one of steam distn., the phenol obtained should be of exceptional quality. C. R. FELLERS

What amounts of nutrient substances present in the effluent of a potato-starch factory are adapted to meadow irrigation? Are these poisonous to fish? EBELING. *Mitt. Fisch. Ver.* 32, 521-2(1928); *Wasser u. Abwasser* 25, 214.—Following up the observation of Parow (C. A. 22, 2218) to the effect that effluents from potato-starch factories are destructive to fish, E. proves that because of the high content of nutritive substances in this waste water, decompn. and fermentation occur. The high org. content consumes the O present, gives rise to prolific mold growths and contains saponin. The latter causes death to fish by its action on the gills. Waste waters from potato-starch factories should be well dild. before use in meadow irrigation projects. Serious pollution and injury to fish-life occur unless the sewage is first treated so as to eliminate the sol. and suspended solids. C. R. FELLERS

Progress in the treatment of paper-mill and tannery wastes. W. W. HODGE. *W. Va. Univ. Coll. of Eng. Tech. Bull.* No. 2, 47-61(1928).—H. reviews work done in Wis. and Mass. (cf. C. A. 21, 3996; 23, 1707, 1709). In W. Va. several tanneries, pulp and paper mills, saw mills, etc., have installed waste-treatment units. One tannery after neutralizing acid waste with alk. wastes, and after sedimentation, runs the clear neutral liquor into the stream. The progress made in the last 5 yrs. indicates that objectionable wastes from industrial plants can be better treated before going into streams. C. H. BADGER

Smoke abatement problem in Osaka. KENOSUKE TSUJIMOTO. *J. Fuel Soc. (Japan)* 8, 253-68(1929).—A review and discussion. F. I. NAKAMURA

**Preventing incrustation in boilers.** J. GORDON. Brit. 299,073, May 17, 1927. A sol. carbonate is added to the boiler water in such proportions that Ca is pptd. as carbonate, which forms a non-adherent sludge. The conditions of the treatment are also favorable for the pptn. of Mg and Fe salts, silicates and some other impurities in non-adherent form.  $\text{Na}_2\text{CO}_3$ ,  $\text{NaHCO}_3$ , or  $\text{BaCO}_3$  may be added, the latter serving to reduce the  $\text{SO}_4$  content of the water by pptn. of  $\text{BaSO}_4$ . A chart of different concns. suitable for avoiding pptn. of  $\text{CaSO}_4$  is given. Brit. 299,074 specifies adding a sol. phosphate to the boiler water to ppt. Ca phosphate as a sludge. A fluoride or arsenate also may be used for the production of a non-adherent ppt. Most of the Ca and Mg are preferably removed by a preliminary treatment with lime and  $\text{Na}_2\text{CO}_3$ . A chart of appropriate concns. of reagent is given.

**Preventing or removing boiler incrustation.** J. D. RIEDEL-E. DE HAËN A.-G. Ger. 474,272, Nov. 21, 1922. Water-insol. inorg. substances, e. g., alumina, kaolin, or graphite, are kept in colloidal suspension in the water.

**Treating cannery waste.** JOHN T. TRAVERS. U. S. 1,711,105, April 30. To avoid stream pollution by cannery waste, the waste is rendered alk. (suitably by  $\text{Ca}(\text{OH})_2$ ) and treated with a sol. Ca salt, such as  $\text{CaSO}_4$ , and with sulfate of Al or Fe or other suitable coagulating agent and a primary Ca phosphate.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

**American soils as seen by Russian investigators.** J. S. JOFFE AND I. ANTIPOV-KARATAEV. *Soil Science* 27, 159-66(1929). J. J. SKINNER

**Lime penetration resulting from surface application to pasture land.** P. R. NELSON. Mass. Agr. Expt. Sta. *Soil Science* 27, 143-6(1929).—From a study of the Ca content and the  $p_H$  values of the treated and untreated pasture soils it has been found that the greater part of the Ca has remained at the point of application and exerted its influence there. The  $p_H$  values show a trend toward a gradual penetration as indicated by a slight, though consistent, neutralization of the soil acidity to a depth of 9 in. The only fertilizer which has had the slightest neutralizing effect upon the soil is gypsum and its effect has not influenced the change in acidity caused by the application of lime alone.

J. J. SKINNER

**Effect of crop growth on the replaceable bases in some California soils.** J. C. MARTIN. Univ. of Calif. *Soil Science* 27, 123-36(1929).—The quantities of exchangeable bases in clay or silty clay loam soils are generally much higher than in the sandy loam soils. When the soils were subjected to a prolonged period of cropping annually to barley or were cropped twice with a long fallow period intervening, there were no appreciable changes in the content of total replaceable bases. There were significant decreases of replaceable K in all soils cropped annually for 12 years. Nine of the 12 soils, which supported 2 barley crops with a 10-year fallow period intervening, show significant decreases in K. The content of total bases is not significantly altered by these decreases in K, because Ca and Mg, which comprise 90% of the total, remain const. The loss of K from the entire group of soils supporting an annual crop of barley for 12 successive years is 32% of that contained in these soils at the beginning of the expt. and is 82% of the K removed in the crops from these soils. The losses of K from the same original group of soils which have supported 2 crops of barley with an intervening fallow period of 10 years, are of questionable significance in several cases, but for the entire group, make up 13% of the original content and constitute 64% of the crop withdrawal. The data seem to be significant, since this expt. has been conducted under conditions which preclude the loss of any of the 4 bases from the soil except by crop withdrawals. These relations between losses of K and crop withdrawals of this constituent suggest the importance of the replaceable base complex with respect to available K in soils. The 0.05 N HCl extractable bases in these soils are compared to the  $\text{NH}_4$  acetate replaceable bases and their relations discussed briefly.

J. J. SKINNER

**Microbiological activities in the soil of an upland bog in Eastern North Carolina.** IVAN V. SHUNK. North Carolina State Coll. *Soil Science* 27, 283-303(1929).—Nitrification did not occur in a bog soil under natural conditions. It was made to occur by liming and drainage as detd. by pot expts., but only after an interval of 6 to 10 weeks. No leguminous plants are found growing on the bog and yet the soil contains 0.24% of total N. The addn. of enough lime to the soil to neutralize the acidity results in a great increase in the nos. of bacteria, but does not appreciably change the nos. of fungi. Lim-

ing the soil markedly increases the rate of  $\text{CO}_2$  production by the soil microorganisms. When the soil is neutralized with lime and allowed to become quite dry, *Actinomyces* becomes abundant. Cellulose added to the soil in the form of filter paper is very slowly decompd. on account of the lack of available N. J. J. SKINNER

Studies on the periodicity of the soil respiration and the microbe activity of the forest soil. D. FÉHÉR. Botan. Inst., Sopron, Hungary. *Biochem. Z.* 206, 416-35 (1929).—The bacterial activity of the soil stands in direct relation to the solar energy. The bacterial content as well as the soil and air temp. together with the light intensity reach a min. value during the winter months, and then a max. value in June and July. The soil respiration is generally completely suspended at temps. below  $0^\circ$ . The respiration as manifested in the  $\text{CO}_2$  production varies parallel with the aerobic organisms. The activity and no. of soil protozoa have no noticeable influence on the soil respiration. The total no. of cellulose-hydrolyzing bacteria (aerobes and anaerobes) varies with the total no. of organisms in the soil, which is more or less also true for the bacteria that ferment butyric acid and urea. The distribution of nitrifying and of denitrifying organisms is likewise affected seasonally. No direct connection could be demonstrated between the variations in  $\text{pH}$  and in the humus content and the no. of bacteria. S. MORGULIS

Dispersing soil conglomerates and a new method of isolating particles smaller than 0.001 mm. V. A. SIBIRSKII, with an introduction by M. KH. PIGULEVSKII. *Ann. of the Division of Agr. Machinery, State Inst. Expt. Agron.* (Russian) [2], 2, 129-54 (1927).—Three soil types were used in the expts.: 2 chernozems and 1 podzolized. The fractions 0.25 to 0.01 mm. were sepd. (1) Ten-g. samples were mixed with 100 cc. 1.0  $N$   $\text{NH}_4\text{Cl}$ , filtered, washed with a 80 cc. 0.5  $N$   $\text{Na}_2\text{CO}_3$  soln., then with 25 cc. 0.25  $N$   $\text{KOH}$ . After each treatment the soils were washed with  $\text{H}_2\text{O}$  until no coloration was apparent. The soil fraction was heated with a dil. soln. of  $\text{H}_2\text{O}_2$  and decanted in a Sabanin app. The differences in the weight of the soil before and after treatments gave the amt. of material removed. (2) The fraction 0.25-0.01 mm. was treated as in (1) with  $\text{NH}_4\text{Cl}$ , transferred into a beaker and boiled with 30 cc. of distd.  $\text{H}_2\text{O}$  for 1 hr., then it was decanted in a Sabanin app. The soil was then treated with  $\text{H}_2\text{O}_2$  as in (1) and decanted. The weight of the fraction was detd. before and after each treatment. The substances removed by the  $\text{NH}_4\text{Cl}$ ,  $\text{Na}_2\text{CO}_3$  and  $\text{KOH}$  treatment were considered as the amt. of colloidal humus; the substances removed by the  $\text{H}_2\text{O}_2$  treatment were considered as the oxidized humus. The amt. of substance thus suspended when compared with the amt. obtained by boiling, was less. The amts. of the resp. fractions lower than 0.001 mm. as detd. in the Sabanin app. by the 2 methods did not correspond. An approach to study the problem was also made in a different way: 3.75 g. of chernozem was mixed with 50 cc. of  $\text{H}_2\text{O}$  and sieved through a 0.25-mm. sieve. To the mixt. 50 cc. of 0.1  $N$   $\text{NaOH}$  was added, heated and dry  $\text{Cl}$  gas free from  $\text{HCl}$  was passed into the mixt. for 10 mins. The rich chernozem gave a dark-yellow supernatant liquid; the poor chernozem gave a light-yellow liquid. The liquid was removed by siphoning. 50-100 cc. of 0.1  $N$   $\text{NaOH}$  was added again and heated on the bath.  $\text{Cl}$  gas passed again and decanted as before. The soil was then placed on a funnel and washed to remove the electrolytes until no  $\text{Cl}$  could be detected. The soil was then transferred to a Sabanin app. and the various fractions were sepd. The org. material because of this treatment goes through the following changes: At first the color is black, changing to dark brown and then to yellow. With the increase of the electrolytes the colloidal substances settle and the liquid remains yellowish green because of some colloidal soln. of the humus complex fraction. In the alk. medium satd. with  $\text{Cl}$  gas 3 products are found:  $\text{NaOCl}$ ,  $\text{NaCl}$  and  $\text{H}_2\text{O}$ ; the org. substances are converted into new compds., which are peptized in the presence of the  $\text{OH}$  ions. A comparison of this method with the Sabanin and the  $\text{H}_2\text{O}_2$  methods shows that it disperses the soil more efficiently, not influencing the mineral fraction. J. S. JOFFE

Relation of temperature to the amount of nitrogen in soils. HANS JENNY. Univ. of Missouri. *Soil Science* 27, 169-88(1929).—See *C. A.* 22, 4702. J. J. SKINNER

Some observations on the effect of the high concentration of organic or ammoniacal nitrogen on nitrification in soil. N. V. JOSHI. *Agr. J. India* 23, 473-81(1928).—In lab. nitrification expts., with soil taken from fields recently brought into cultivation it was found that when more than 90 mg. of N from  $(\text{NH}_4)_2\text{SO}_4$  or oil cake were used per 100 g. soil there was no accumulation of nitrates but large quantities of  $\text{NH}_3$  and sometimes nitrites were present. However, when the soil was first incubated with 90 mg. of N from oil cake or  $(\text{NH}_4)_2\text{SO}_4$  for about 6 weeks and then washed free of nitrates, it was found that the washed soil could nitrify as much as 120 mg. of N per 100 g. of soil without the accumulation of  $\text{NH}_3$ , indicating that the soil treated in this way was activated in

such a manner as to be able to nitrify large quantities of org. or ammoniacal N. J. attributes this phenomenon to a large increase in the no. of nitrifying organisms and a proportionate decrease in the no. of non-nitrifying organisms. This was borne out by expts. in which relatively pure cultures of organisms capable of forming nitrites and nitrates were added to 100-g. samples of soil contg. 120 mg. of org. or ammoniacal N, the rate of nitrification being appreciably increased in each case. The rate of nitrite formation was not appreciably increased. In comparative expts. with oil cake,  $(\text{NH}_4)_2\text{SO}_4$ ,  $\text{NaNO}_2$  and  $\text{KNO}_3$ , it was found that recovery of N in the form of  $\text{NH}_3$ , nitrite and nitrate was lowest with  $\text{NaNO}_2$ , followed in order by  $(\text{NH}_4)_2\text{SO}_4$ . This is explained on the assumption that the N is converted into org. N or else escapes as free N. When active nitrification was going on the no. of organisms in the soil was maintained at a higher level for a longer period of time than in those cases where nitrification did not proceed.

K. D. JACOB

**Influence of various forest types on nitrate content and formation in forest soils.** A. NEMEC AND K. KVAPIL. *Z. Forst- u. Jagdwesen* 1927, 322-412.—The nitrate content of different soil horizons under various types of forest was studied, and nitrifying ability correlated with the type of vegetation. Nitrifying ability was detd. from the rate of accumulation of nitrate in samples of soil. Nitrate content varied with the depth of the horizon, surface litter and mold being generally richest. In both coniferous and deciduous forests free from undergrowth there was little or no nitrification at any horizon, and even a tendency to denitrification when the surface layer was highly acid. The existence of an undergrowth was accompanied by considerable nitrifying power in the humus layers; certain plants were suggested as indicators of nitrifying ability in forest soils. In clearings there was a striking increase in nitrifying ability, attributed to the accelerating action of direct sunlight on the decompn. of litter material.

B. C. A.

**The influence of manganiferous soils on the accuracy of the quinhydrone electrode.** W. T. MCGEORGE. Hawaiian Sugar Planters' Assoc. Expt. Sta. *Soil Science* 27, 83-8 (1929).—The accuracy of the quinhydrone for the detn. of soil reaction is greatly affected by the presence of small quantities of  $\text{MnO}_2$ . The drift shown by the potentiometer with manganiferous soils is sufficiently rapid and characteristic to warn the analyst against reporting erroneous results on such types.

J. J. SKINNER

**The effect of moisture content and cropping on exchangeable calcium and magnesium, with particular reference to rice soil.** W. H. METZGER. Arkansas Agr. Expt. Sta. *Soil Science* 27, 305-18 (1929).—The results of a study of the exchangeable Ca and Mg of a soil cropped to rice for a long period of time are reported. Crowley silt loam cropped to rice for 15 of the past 20 years showed considerably more exchangeable Ca and Mg in the surface soil than in the sub-surface horizon. Clarksville silt loam kept at a moisture content of 20% with distd.  $\text{H}_2\text{O}$  for a period of 75 days increased the exchangeable Mg as compared to the same soil kept air-dry. Exchangeable Ca was not appreciably changed. Flooding with distd.  $\text{H}_2\text{O}$  for the same period of time depressed the amt. of exchangeable Ca, but increased the amt. of exchangeable Mg.

J. J. SKINNER

**The influence of organic matter and lime on soil moisture and on the percentage of carbon and nitrogen in field plots.** J. F. MULLER. Rutgers Coll. *Soil Science* 27, 137-41 (1929).—In all cases but one, those soils from exptl. plots receiving an annual application of org. matter show a higher moisture content than those receiving no treatment or only minerals. In all cases but 2, those soils receiving lime show a lower moisture content than the corresponding soils receiving no lime. The addn. of org. matter increases the moisture content approx. twice as much as the addn. of lime decreases it. The soils receiving annual applications of org. matter, as manure or straw, show an increase in total C over the amt. originally present. Those receiving manure show an increase in total N also. All other plots show a decrease in these 2 elements.

J. J. SKINNER

**The influence of the distance between rows of sugar beets upon the absorption of nutrition from the soil.** J. SOUČEK. *Listy Cukrov. 47*, 365-8 (1929).—Beginning in June, the wt. of the individual green and the av. wt. of the beet root increases with an increasing distance between rows. The percent of dry matter was the same for all widths of rows with a minor exception in the root of the wider rows, where a decrease occurred from Aug. 28. The av. wt. of dry matter increased with the wide rows from Aug. onward for both root and green. With the progress in ripening the quantity of dry matter increased chiefly in the most widely spaced rows. On June 26, the sugar contents of all the rows were the same; during July and Aug., the narrowest row showed the highest sugar content, and the widest row the lowest; the last (Nov.) analysis showed the highest (19.90%) sugar content for the 45-cm. row, 19.65% for the 35-cm. row, 19.18% for the 55-cm. row. The yield of sugar per plant remained the same for all rows

until Aug.; the 35-cm. row yielded the least in Aug; in Nov. the yield for the 55-cm. row was 162.6 g., 45-cm. row 125.2 g. and 35-cm. row 87 g. The percentage of ash remained about the same for greens and roots during the early part of the season but became highest in the widest rows at the close of the season. During the month of July, the 55-cm. rows showed the highest av. ash content which persisted to the end of the season. The % N was the same for all rows throughout the entire season; the av. N content became the largest for the widest row from July to Sept.; the lowest N content at the end of the season is found in the 45-cm. row and is compensated for by a higher sugar content. The quantity of N absorbed from the soil by an individual plant increased with a greater distance between rows. The percentage content of  $P_2O_5$  was the same for the 3 rows throughout the entire season; the total content of  $P_2O_5$  began to increase in the 55-cm. row in Aug. and continued until the end of the season—the greatest yield being in the 55-cm. row and the least in the 35-cm. row. The %  $K_2O$  was the same for all 3 rows and remained equal throughout the season; the av.  $K_2O$  content per plant increased with a widening of the rows. Although the distances between the rows of beets were variable, the absorption of nutrition from the soil was the same per 100 kg. of beets grown.

FRANK MARSH

A new cycle of phosphate digestion with acid. S. I. VOLFKOVICH AND V. P. KAMZOLKIN. *Trans. Sci. Inst. Fertilizers* (Moscow) 1928, No. 55, 121-37.—The reactions theoretically possible between raw phosphates,  $H_2SO_4$  and  $(NH_4)_2SO_4$ , have been tested experimentally. Low-grade phosphates (21.5%  $P_2O_5$ , 14.3%  $(Al, Fe)_2O_3$  and 3.2%  $CO_2$ ) were mixed with a 20% soln. of  $(NH_4)_2SO_4$  and to this mixt. concd.  $H_2SO_4$  was added with stirring. The quantities of  $(NH_4)_2SO_4$  and  $H_2SO_4$  were calcd. from the equations:  $2Ca_3P_2O_8 + 5H_2SO_4 + (NH_4)_2SO_4 = 6CaSO_4 + 2NH_4H_2PO_4 + 2H_3PO_4$ ;  $Ca_3P_2O_8 + 2H_2SO_4 + (NH_4)_2SO_4 = 3CaSO_4 + 2NH_4H_2PO_4$ . The concn. of the liquid phase was made up so that the soln. should contain 15-20% free  $H_2SO_4$ . The soln. was sepd. from the sediment by filtration; the sediment (phosphogypsum) was washed with water equal in weight to  $\frac{1}{2}$  that of the phosphate. The temp. at the time of mixing never went beyond 36-42°. By using a 10% excess of  $H_2SO_4$ , 90% of the phosphate decomposed. The concn. of the ext. from the first leaching was: 8.0-8.3%  $P_2O_5$  and 3.1% ammonia. The sesquioxide content in the ext. varied from 1.4 to 1.8%. The phosphogypsum was (1) treated with  $NH_3$  water and then  $CO_2$  passed through the suspension; (2) mixed with water and then  $CO_2$  and  $NH_3$  gas passed through the suspension. Higher yields of  $(NH_4)_2SO_4$  were obtained by the first method. With a 10% excess of  $NH_3$  and  $CO_2$  (above the stoichiometric) as high as 95.5-97.6% of the  $SO_3$  has been recovered from the phosphogypsum. The temp. range was 12-47°. Natural gypsum when treated in the same manner did not decompose as rapidly as the gypsum from the phosphoric acid process. A 78% soln. of  $H_2SO_4$  was dild. to 28-35% with a 20-26% soln. of  $NH_4H_2PO_4$ , mixed with raw phosphates and kept for 3 hrs. at 90-120° in a kettle as in the chamber process of acid phosphate manuf. The product contained 25%  $P_2O_5$ , of which 90-95% was available, and 70-73%  $H_2O$ -sol., with 3% N. The product is dry, mellow and upon storing does not revert. Another method of utilizing low-grade phosphates is to neutralize the weak soln. of  $H_3PO_4$  obtained from them with  $NH_3$  gas. A German summary is given.

J. S. JOFFE

The precipitation of phosphoric acid with lime water. E. V. BRITZKE AND S. S. DRAGUNOV. *Trans. Sci. Inst. Fertilizers* (Moscow), 1928, No. 55, 7-28.—Citrate-sol. phosphate can easily be prepd. from phosphoric acid by the addn. of lime water by observing the following: the  $CaO$  is to be pure, added slowly with stirring to a reaction point at which methyl red turns from its red coloration to orange. All the phosphoric acid is then pptd. Such ppt. may be dried satisfactorily at 60-70°. Solns. with less than 1%  $P_2O_5$  are not pptd. completely. Such a ppt. is sol. in  $NH_4HSO_4$ . J. S. J.

Laboratory experiments on the utilization of fluorine in the manufacture of superphosphate. S. I. VOLFKOVICH. *Trans. Sci. Inst. Fertilizers* (Moscow) 1928, No. 55, 29-71.—The optimum conditions for the production of  $Na_2SiF_6$  by treating  $H_2SiF_6$  with  $NaCl$  in connection with the recovery of F in the process of mfg. acid phosphate were: 9-12% of  $H_2SiF_6$  and 20%  $NaCl$ , mixing 10 mins. and allowing to settle 25-30 mins. Expts. on the production of  $NaF$  from  $Na_2SiF_6$  and a soln. of  $Na_2CO_3$  show that the amt. of  $Na_2CO_3$  has to exceed the stoichiometric value by 10%. For a high yield of ppt. 8% concn. of  $Na_2CO_3$  is desirable, but the total yield is low. In order to get the max. yield of  $NaF$ , 5-6% of  $Na_2CO_3$  is better. The temp. of the reaction was kept at 90-105°. The method of fusing  $Na_2SiF_6$  with  $Na_2CO_3$  and leaching the fused mass was also tried. It was possible to obtain 92.2% of  $NaF$  (from the theoretical in respect of the  $Na_2SiF_6$ ) by using water at the boiling temp. The product is purer than that obtained by using  $Na_2CO_3$  soln. The third method investigated was to heat  $Na_2SiF_6$  to a high temp.

thereby decompg. it into  $\text{NaF}$  and  $\text{SiF}_4$ , the latter being absorbed again to form  $\text{H}_2\text{SiF}_6$ . At  $600-830^\circ$  the  $\text{Na}_2\text{SiF}_6$  decomposes fast enough on a large factory scale. The evolution of  $\text{SiF}_4$  begins at  $580-590^\circ$ . Lab. expts. show that with a 3-mm. layer of  $\text{Na}_2\text{SiF}_6$ , the decompn. may be completed in 15-20 mins. with a temp. of  $620-640^\circ$ . This leaves a residue with 0.1-0.7%  $\text{SiF}_4$ . For the production of cryolite the optimum conditions in respect of temp., concn. of reagents, time and quant. relations of the reagents were: the highest yield (86.4%) was obtained at  $90^\circ$ ; the optimum concn. of the solid phase was 8%; the optimum time was 60 mins.; an increase of 10% of  $\text{Al}_2\text{O}_3$  above the stoichiometric value increased the yield by 3% only; addnl. increases of  $\text{Al}_2\text{O}_3$  gave no yield increase above the 3%. The  $\text{SiO}_2$  in soln. was found to be in the colloidal state. A German summary is given.

J. S. JOFFE

The moisture content and hygroscopicity of superphosphate. S. I. VOLFKOVICH AND L. V. VLADIMIROV. *Trans. Sci. Inst. Fertilizers* (Moscow) 1928, No. 55, 73-98.—An excess of acid in superphosphate under humid conditions increases its moisture content. In the semi-arid regions an excess of acid has no effect on the moisture content. To decrease the moisture content the superphosphate should be spread out in thin layers while still hot and piled up when cold. Artificial drying causes slight reversion of phosphates, but this reversion becomes const. and does not increase upon further storing. High moisture content and acidity and low temps. of storing reduce the amount of reversion. A German summary is given.

J. S. JOFFE

The free phosphoric acid in low-grade superphosphate and methods of determining it. S. I. VOLFKOVICH AND L. V. VLADIMIROV. *Trans. Sci. Inst. Fertilizers* (Moscow) 1928, No. 55, 99-120.—By using acetone instead of water, alc. or ether the free phosphoric acid can easily be titrated with methyl red as an indicator. The acetone has the advantage over the other extn. materials that no hydrolysis of the Fe and Al compds. takes place; neither does the monophosphate decompose to give free  $\text{H}_3\text{PO}_4$ .

J. S. JOFFE

Investigations on decomposition and action of nitrogen and carbon compounds contained in stable manure. KURT SCHEIBE. *Landw. Vers. Sta.* 108, 61-114(1929).—The N loss of the uppermost layers can be essentially reduced by covering the manure piles with soil. With hot manure the action of the 3-months-old manure was about 26-31% better than with comparison material stored only 4-6 weeks; with immediately compactly stored manure on the other hand the action declines in the same time about 14%. In small quantities of soil 35.2% of the total N of the stable manure in loosely packed material was converted into saltpeter, with immediately compactly stored manure 27.9% and with farm manure 18.2%. The max. saltpeter formation was attained sooner with hot manure. The carbonic acid production in the soil was increased about 43% in a field expt. with carrots by fertilizing with farm manure, with hot manure on the other hand about 160%. With potatoes the carbonic acid increased about 23% with fertilization with farm manure, with compactly stored manure about 41% and with hot manure about 102%. Further field expts. are described. E. F. SNYDER

Recent developments in practical plant feeding. C. HEIGHAM. *Proc. Univ. Durham. Phil. Soc.* 8, Pt. 1, 25-39(1927-28).—A general article on fertilizers.

ALBERT L. HENNE

Potato fertilizer experiments. J. H. STALLINGS. Penney Farms, Florida. *Soil Science* 26, 351-62(1928).—The 2000 lb. rate application of fertilizer was the most economical rate used.  $\text{K}_2\text{SO}_4$  has no decided advantage over  $\text{KCl}$  as a source of  $\text{K}_2\text{O}$  on potato yield. The present practice of supplying, in potato fertilizers, N from several sources, including expensive org. materials, may be ill-founded.  $\text{NaNO}_3$ ,  $(\text{NH}_4)_2\text{SO}_4$ , 10% blood and bone tankage,  $\text{Ca}(\text{NO}_3)_2$  when used singly and in the combinations reported, were about as satisfactory as sources of N for potatoes as the combination used in the standard potato fertilizer mixt. Ammo-phos was unsatisfactory as a source of N for potatoes.  $\text{K}_2\text{SO}_4$  and  $(\text{NH}_4)_2\text{SO}_4$  increased potato yields when used as top dressers.

E. F. SNYDER

The pot culture method of Prof. Mitscherlich for the determination of potash requirements. LAMBERG. *Ernähr. Pflanze* 25, 169-73(1929).—The results of field tests on soils of which the potash requirements had been detd. by the Mitscherlich method, show the practical usefulness of this method (cf. C. A. 18, 2053). L. P. M.

Minimum potassium level required by tomato plants grown in water cultures. EARL S. JOHNSTON AND D. R. HOAGLAND. Univ. of Maryland. *Soil Science* 27, 89-106(1929).—With a newly devised flowing soln. app., expts. were undertaken to det. the min. K level requirement of the tomato plant. Under the given exptl. conditions, which were kept within a range for good growth, it was found that opt. growth was maintained at a K concn. of approx. 5 p. p. m. at the intake. The rate of flow for such a soln. averaged

8 cc. per min. per plant. The plants were grown for a period of 45 days. In expts. where the initial K concn. of 3.7 p. p. m. was reduced to 0.7 p. p. m. or even to 1.4 p. p. m., actual analysis of the plants showed a marked decrease in K absorbed and a tendency toward increased Ca, Mg and P absorption as compared with check plants. A characteristic spotting of leaves indicating "potash hunger" is very marked in tomato plants grown in solns. in which the K concn. is maintained below a certain level. Attention is called to certain interesting relations between K concns. and light values, as suggested by one of the expts. J. J. SKINNER

**Chemical weed killers.** S. H. VIGOR. Sask. Dept. Agr. Regina. *Sci. Agr.* 9, 587-93(1929).—FeSO<sub>4</sub> (20% soln.) sprayed at the rate of 100 lb. per acre on oats or barley fields badly infested with wild mustard, destroyed the latter without great injury to the grain crops. A spray consisting of NaClO<sub>3</sub> 25%, CaCl<sub>2</sub> 14%, and H<sub>2</sub>O 61% effectively destroyed perennial sowthistle and dandelion. C. R. FELLERS

**The use in agriculture of copper thiocyanate.** A. PAILLOT AND R. PUSSARD. *Compt. rend. acad. agr. France* 15, 501-5(1929).—The thiocyanate can be employed in the same conditions as the ordinary Cu mixts. for treatment of fruit trees. The prepn. of the mixt. or emulsion is very simple, since it suffices to mix the thiocyanate in water; this diln. should be made at first in a small quantity of water to avoid the formation of lumps. One should add Pb or Ca arsenate to the mixt. so as to make it sufficiently insecticidal; where one uses Ca arsenate it is wise to add some lime to avoid the burning of the foliage. E. F. SNYDER

**A preliminary report on experiments in the control of grain smut of jowar (Andropogon sorghum).** B. N. UPPAL AND J. S. MALELU. Dept. Agr. Bombay Presidency. *Agr. J. India* 23, 471-2(1928).—Seeds of *Andropogon sorghum* were artificially infected with spores of *Sphacelotheca sorghi* at rates varying from 1 part by wt. of smut spores to 250 parts of seed down to 1 to 3000, and were treated with Cu carbonate (53% Cu), 100-mesh S, 200-mesh S, CuSO<sub>4</sub> (coarse powder), and CuSO<sub>4</sub> (200-mesh), resp., all fungicides being applied as dry dusts. Cu carbonate at the rate of 1 ounce per 60 lb. of wheat gave complete control of smut in seed contg. 1 part of spores to 1000 parts of seed, infection being very slight with heavier spore loads. Similar results were obtained with 200-mesh S applied at the rate of 2 ounces per 60 lb. of wheat. The results with 100-mesh S were less satisfactory. Control of smut was not obtained in any cases with the coarsely ground CuSO<sub>4</sub>, but almost complete control was obtained with 200-mesh CuSO<sub>4</sub> except at the heaviest infection. K. D. JACOB

**Effect of carbon disulfide treatment of soil for the Japanese beetle on the abundance of microorganisms and on the ammonia and nitrate content.** WALTER E. FLEMING. U. S. Dept. Agr. *Soil Science* 27, 153-8(1929); cf. *C. A.* 23, 1206.—A Sassafras loamy sand was treated with the concn. of gaseous and of emulsified CS<sub>2</sub> used for the immature stages of the Japanese beetle, and observations were made on the effects on the microorganisms and on the concn. of NH<sub>3</sub> and NO<sub>3</sub> in the soil. Treatment with 0.05% CS<sub>2</sub> (1 lb. to 1 cu. yd.) did not affect the density of the bacterial population appreciably, but it stimulated the development of fungi. It also caused an accumulation of NH<sub>3</sub>. Treatment under lab. conditions with 0.05% CS<sub>2</sub> emulsion was not satisfactory. The detrimental effect on the bacteria and fungi, the accumulation of NH<sub>3</sub>, and the decrease in the concn. of NO<sub>3</sub> in the soil are probably factors involved in causing the injury following treatment of ornamentals in poorly drained fields, or in fields puddled by the application of large vol. of water. It is probable that the results of treatment of well-drained, fertile soils with this concn. of CS<sub>2</sub> emulsion are very similar to those of fumigation when the same quantity of the gas is used. Treatment with 0.05% CS<sub>2</sub>, either as gas or as emulsion, results in an accumulation of NH<sub>3</sub> and in a change in the nos. of microorganisms. Care should be taken to aerate the soil after fumigation, and the emulsion treatment should be used only in well-drained soil, so as to avoid, as far as possible, excessive accumulations of NH<sub>3</sub>. J. J. SKINNER

**Fertilizer.** I. G. FARBERIND. A.-G. (Hugo Weitzel, inventor). Ger. 474,972, Sept. 16, 1924. A fertilizer consists of a mixt. of  $\text{NH}_4\text{NO}_3$  and  $\text{K}_2\text{SO}_4$  in the mol. proportions of about 4 to 1. Cf. *C. A.* 23, 2238, 2239.

**Fertilizers.** Soc. D'ÉLECTROCHIMIE, D'ÉLECTROMETALLURGIE ET DES ACIÉRIES ÉLECTRIQUES D'UGINE and THÉODORE HÆGE. Fr. 648,834, June 28, 1927. A fertilizer contg. phosphates of K and  $\text{NH}_4$  is prepd. by combining a reduction of the Ca phosphate with  $\text{SiO}_2$  and charcoal with a volatilization of the potash contd. in the rocks the  $\text{SiO}_2$  of which is used in the reduction, then transforming, after oxidation, into a mixt. of phosphates of K and  $\text{NH}_4$  the vapors of P and potash liberated. The reduction and volatilization take place in an elec. furnace.

**Anti-parasite preparation for seed goods and the like.** PERMUTT A.-G. (Otto Liebknecht, inventor). Ger. 472,738, Jan. 20, 1926. Dairy and horticultural materials are protected from damage by animal and vegetable parasites by volatile or gaseous Cr compds. These compds. may be used with other volatile or gaseous compds. An example is chromyl halide, with or without, halogenated hydrocarbon.

## 17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

**Chemical and physical incompatibilities of antipyrine.** VIRGILIO LUCAS. *Rev. chim. pharm. militar Rio de Janeiro* 4, 142-3 (1928).—Antipyrine should not be mixed with one of the following substances:  $\text{FeCl}_3$ , picric acid,  $\text{CCl}_3\text{CO}_2\text{H}$ , salicylic acid,  $\text{HgCl}_2$ ,  $\text{I}$  and its prepn., tannin and its prepn., sweet spirit of nitrous ether, Na salicylate with Mg salts, asapol, aspirin, acetanilide, thymol, naphthol, menthol. The reactions with these substances are explained.

A. E. MEYER

**Caffeine-salicylic acid, a molecular compound.** N. SCHOORL. Univ. Utrecht. *Pharm. Weekblad* 66, 357-8 (1929).—Regenbogen and Schoorl (*C. A.* 18, 880) showed that caffeine and salicylic acid form a mol. compd. with m. p.  $137^\circ$ , and suggested that the greatly increased soly. of caffeine in the presence of Na salicylate was due to the formation of the Na salt of this complex. The Na salt,  $\text{C}_8\text{H}_{10}\text{N}_4\text{O}_2\cdot\text{HOC}_6\text{H}_4\text{CO}_2\text{Na}\cdot 5\text{H}_2\text{O}$ , has now been prepd. in cryst. form. It is stable in the air and loses  $\text{H}_2\text{O}$  only slowly on the water bath, but it can be dehydrated completely in a desiccator. Most pharmacopeias allow only 4-5% for the  $\text{H}_2\text{O}$  content of *Salicylas natricus cum caffeineo*, whereas the stable air-dry salt actually contains 20%  $\text{H}_2\text{O}$ .

A. W. DOX

**Preliminary note on the chemistry of concrete otto of *Boronia megastigma* (Nees).** A. R. PENFOLD. *J. Roy Soc. West. Australia*, 14, 1 (1927); *Australian Science Abstracts* 7, 27. The results of the examn. of com. samples of concrete otto of *Boronia megastigma* are given: m. p.  $35-40^\circ$ , sp. gr. 0.9091-9173,  $n$  ( $38-40^\circ$ ) 1.4752-1.4852, acid no. 24-30, ester no. 96-110, acetyl no. 140-148. Constituents identified: triacontane, m.  $64^\circ$ , a glyceride of palmitic and stearic acids, phytosterols, free palmitic, formic and caprylic acids. These constituents form excellent fixatives for odoriferous components consisting of unknown alc. with  $\beta$ -ionone.

H. L. D.

**Essential oils of Caucasian and Crimean Thymus.** B. N. RUTOVSKII and I. V. VINOGRADOVA. *Trans. Sci. Chem.-Pharm. Inst. (Moscow)* 1927, No. 17, 98-108.—A sample of oil from *Thymus vulgaris* L. was extd. with 8% NaOH and the phenols thus obtained were treated with  $\text{Pb}(\text{OAc})_2$ , giving compds. of thymol and carvacrol. The former m.  $48-50^\circ$  and gave *o*-thymolcarboxylic acid, m.  $123^\circ$ ; the latter gave nitrosocarvacrol, m.  $151-2^\circ$ . The ratio of thymol to carvacrol was 2:1. The oil from the alkali extn. was fractionally distd. The various const. for the fractions are given. No  $\alpha$ -pinene was found in fraction Ia. Fraction Ib upon oxidation gave *p*-hydroxyisopropylbenzoic acid, which indicates the presence of *p*-cymene. No ketones or aldehydes were present in fraction II. It gave citral upon oxidation with chromic acid; this indicates the presence of *l*-linalool, which was sepd. from fraction III by phthalic acid ester and its const. are:  $d_{20}^{20}$  0.8698;  $[\alpha]_D -12.75^\circ$ ;  $n_D^{20}$  1.4687. In fraction IV borneol could be demonstrated. Upon sepn. with phthalic acid anhydride, it m.  $201-2^\circ$ ; phenylurethan, m.  $138^\circ$ . The sesquiterpene fraction gave no nitrosochloride or nitrosate.

J. S. J.

**Urea-stibamine: its preparation and composition.** SUDHAMOY GHOSH, R. N. CHOPRA and NIHAR RANJAN CHATTERJEE. Calcutta School of Trop. Med. *Indian J. Med. Research* 16, 461-8 (1929).—Sodium antimonate is prepd. by dissolving  $\text{Sb}_2\text{O}_3$

(7.2 g.) in HCl (34 cc. of d. = 1.23 at 15.50). This soln. is gradually added, with stirring, to warm 20% NaOH (30 g. in 150 cc. H<sub>2</sub>O). The resulting slightly opalescent soln. is kept at 0°. *p*-Aminoacetanilide is gradually added to cooled dil. H<sub>2</sub>SO<sub>4</sub> (4 cc. concd. H<sub>2</sub>SO<sub>4</sub> in 50 cc. H<sub>2</sub>O). NaNO<sub>2</sub> (4 g.) is added cautiously (without allowing the soln. to become warm). The diazotized amine soln. (bright cherry-red color after the operation is finished) is slowly added to the Na antimonite and vigorously stirred for 2 hrs., the temp. regulated at 1 to 2° C. When evolution of N ceases, 500 cc. H<sub>2</sub>O is added, neutralized with dil. H<sub>2</sub>SO<sub>4</sub> (1 in 10), CO<sub>2</sub> is passed through and the unchanged Sb<sub>2</sub>O<sub>3</sub> filtered off. The red-brown filtrate is satd. with NaCl and the resulting Na salt sepg. as a flocculent ppt. is air-dried and purified from MeOH. Acetyl-*p*-aminophenylstibinic acid is pptd. by treating an aq. soln. with dil. HCl. This ppt. is dissolved in 5% NaOH at 60° and an equal wt. of urea is added, heated on a water bath and concd. to 1/2 vol. After the concd. soln. is cooled it is treated with abs. alc. Urea stibamine is pptd. The N and Sb contents vary greatly from different samples on the market. FRANCES KRASNOW

Simple and quick microchemical methods for tobacco analysis. II. A titration procedure for determining nicotine in fresh green tobacco. J. BODNAR AND VITÉZ LADISLAUS NAGY. *Biochem. Z.* 206, 410-5(1929); cf. *C. A.* 22, 4720.—Fresh green tobacco is dried in a steam oven at 95-97° and powdered. The powder is moistened with an aq. 20% NaOH soln. The drying causes no loss of nicotine. One g. of the powder is weighed in a glass-stoppered 50-cc. flask and is thoroughly mixed with 1 cc. of the alkali. To this is then added 20 cc. of a mixt. of equal vols. of ether and petroleum ether and the ext. is filtered after 2 hrs. Ten cc. of the filtrate is transferred to a 100-cc. Erlenmeyer flask and NH<sub>3</sub> is driven off by passing a current of air. Then, 10 cc. H<sub>2</sub>O, 10-15 cc. 0.01 N HCl and a drop of methyl red are added and the mixt. is titrated with 0.01 N NaOH, each cc. 0.01 N HCl corresponding to 1.62 mg. nicotine. S. MORGULIS

A new reagent for the qualitative and quantitative (nephelometric) determination of quinine. E. I. STERKIN AND J. I. HELFGAT. *Med. Inst., Charkov. Biochem. Z.* 207, 8-24(1929).—Giemsa's reagent is not suitable for the nephelometric detn. of quinine. A new reagent is prepd. by mixing Na<sub>2</sub>AsO<sub>4</sub> and (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> and acidifying with HCl (equal vols. of 0.12% Na<sub>2</sub>AsO<sub>4</sub>, 2% (NH<sub>4</sub>)<sub>2</sub>MoO<sub>4</sub> and 2% HCl). This reagent is the most sensitive known, giving permanent opalescence even with dilns. of 1:2,000,000. One cc. of the reagent is to be added to 5 cc. of the slightly acidified quinine soln. The reagent keeps 4-5 months if preserved in the dark, and it produces no opalescence with blood or tissue exts. free from quinine. With quinine the opalescence is reproducible and proportional to the concn. No opalescence is produced up to the following concns. of various alkaloids: caffeine 1:200,000; apomorphine 1:300,000; morphine 1:6000; cocaine 1:300,000; atropine 1:40,000; plasmochine 1:100,000. S. MORGULIS

Poisonous constituents of *Ryania acuminata*. S. NAKARAI AND T. SANO. *J. Pharm. Soc. (Japan)* 48, 1102-10(1928).—La Cointe extd. from *Ryania acuminata* a poisonous substance, which he named ryanin. Hydrolysis of ryanin gave a glucone which La Cointe has named ryanitin. Root of *Ryania acuminata* (dried at 100°, loses about 20% wt.) was digested on the water bath with water as solvent. The red-brown liquid was clarified with lead acetate, freed from excess Pb by means of H<sub>2</sub>S, concd. and extd. with CHCl<sub>3</sub>. Evapn. of the CHCl<sub>3</sub> left a glass-clear substance which reduced Fehling soln. and probably was identical with ryanin of La Cointe. It is sol. in hot water. To this soln. NaCl was added and the soln. was used for toxicological study by injection into frog, mouse, rabbit, cat, dog and certain fishes. Ryanin has first a stimulating, and then a paralyzing effect on respiration. The action of strychnine is not affected by simultaneous injection of ryanin. F. I. NAKAMURA

Purification of extracts containing the growth-promoting principle of the anterior hypophysis. HAROLD M. TEEL. *Science* 69, 405(1929).—The growth-promoting principle of the anterior hypophysis may be pptd. by the addn. of anhyd. Na<sub>2</sub>SO<sub>4</sub> to a neutralized alk. ext. of the glands. The ppt. is lower in protein content, and sugar, phosphates, uric acid and non-protein N are reduced to traces. An aq. soln. (filtered) is used for injection. Expts. further to fractionate the globulin group of proteins, in which the growth-promoting principle comes down, resulted in a division of the substances between the fractions. N. M. NAYLOR

Estimation of acetylsalicylic acid tablets. AXEL HOFFMAN. *Dansk Tids. Farm.* 3, 82-102(1929).—Acetylsalicylic acid tablets often contain quantities of MgO to remove bitter taste. Four methods of analysis are given: (1) Warm a tablet with 12 cc. 0.5 N NaOH and allow to cool, after which titrate the excess alkali with 0.1 N HCl (indicator, alizarin yellow, *pH* range, 12.1-10.1) The titration must be done rapidly; otherwise some MgO reacts with the HCl. The end point remains for about 1/2-1 min. (2) Extn. with ether.—Place 1 tablet, finely ground, in a 100-cc. long-necked flask fitted

with a glass stopper. Add 50 cc. ether by means of a pipet and shake the mixt. for 5 mins. Allow to stand for 10 mins., and pipet off 25 cc. of the soln. Evap. ether and hydrolyze the acetylsalicylic acid with 0.5 *N* NaOH. Titrate the excess alkali with 0.5 *N* HCl with phenolphthalein as indicator. (3) Bromometric detn. Hydrolyze acetylsalicylic acid with NaOH and later add a slight excess HCl and heat to decomp. MgO. After cooling make up to 100 cc. and allow to stand until most of the talc has settled. Pipet off 10 cc. and add 80 cc. 0.1 *N* KBrO<sub>3</sub>, 1 g. KBr and 5 cc. 4*N* HCl and let the mixt. stand for 20–30 mins., after which add 1 g. dissolved KI and allow to stand for 5 mins. Titrate the excess I<sub>2</sub> with 0.1 *N* Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub> (indicator, starch); 1 cc. 0.1 *N* KBrO<sub>3</sub> = 0.0030 g. acetylsalicylic acid. (4) Det. the color intensity of the reaction between salicylic acid and Fe<sup>+++</sup> salts by means of the spectrophotometer. Break up the tablets in the presence of 1 cc. 4*N* H<sub>2</sub>SO<sub>4</sub> to prevent hydrolysis, and then shake with 10 cc. of a 1–1 mixt. of ether and pentane. Pipet off 5 cc. of the clear liquid and carefully evap. on a steam bath. Dissolve the residue in 20 cc. 25% EtOH and add 0.5 cc. 2% FeCl<sub>3</sub> soln. Then compare the color intensity with that of standard solns.

O. A. NELSON

A study of belladonna. ANGEL TERREL CURVAS. *Mon. farm. therap.* 35, 36–8, 59–63, 81–6(1929).—A complete study of belladonna including a compilation of available information concerning the chemistry of its active constituents. J. L. POWERS

Mayer's reagent and its modifications with alkali and alkaline earth cations. Influence on the sensitivity for the precipitation of strychnine. RAUL GIORDANO, CESARINA RUSSO AND MARIA TERESA LUQUE LOBOS. *Rev. centro estud. farm. y bioquim.* 16, 85–98(1927).—The limit of sensitivity to strychnine of Mayer's reagent prepd. by substituting NH<sub>4</sub>, Na or Rb for K was 1 to 70,000. When Li, Sr and Ba were substituted for K, the sensitivity was 1 in 120,000. Li is recommended as being most satisfactory. J. L. P.

Chemical examination of  $\alpha$ -phenyl- $\beta$ -aminoethanol sulfate. SAMUEL M. GORDON. *Am. Med. Assoc. J. Am. Pharm. Assoc.* 17, 1195–9(1928).—Adrenaline, ephedrine, tyramine and  $\alpha$ -phenyl- $\beta$ -aminoethanol are closely related. The side chain of adrenaline contains 3 C; the others 2; the former is a deriv. of propylbenzene; the others are derivs. of ethylbenzene. Adrenaline and tyramine contain OH in the nucleus, thus rendering them more prone to oxidation than the others. Ephedrine may be removed from solns. by shaking with immiscible solvents; phenylaminoethanol decomps. into C<sub>6</sub>H<sub>5</sub>CHO. The sulfate forms fine, white, odorless crystals; taste bitter; sol. in hot H<sub>2</sub>O; m. 250–4°; optically inactive. The aq. soln. with CuSO<sub>4</sub> and NaOH gives a purple color which is discharged by acids and is insol. in Et<sub>2</sub>O. It gives the carbylamine reaction, thus differing from ephedrine; yellow ppt. with Millon's reagent, which is unchanged by heating; aq. soln. pptd. by PdCl<sub>2</sub> and phosphotungstic acid but not by other common alkaloidal reagents; *picrotonate* m. 200–1°; *monobenzoil compd.* m. 149.5–50°. The substance is anhyd. at 100° and stable. L. E. WARREN

The *Camphorosma monspeliacum* of S. Cesarea (Lecce). F. P. MAZZA AND G. SPAGNOLO. *R. Univ., Naples. Rend. accad. sci. (Napoli)* [3], 34, 51–4(1928).—From *Camphorosma monspeliacum* of the family Chenopodiaceae Cassan obtained by steam distn. 0.2% of a greenish essential oil with an odor of bitter almonds, solid at +4°, *n* = 1.3724. Warmed with KOH it evolved C<sub>6</sub>H<sub>5</sub>NH<sub>2</sub>, being the only essential oil known contg. amino N. M. and S. extd. the upper part of the plant with C<sub>6</sub>H<sub>6</sub>, distd. off the C<sub>6</sub>H<sub>6</sub>, steam distd., and on extn. of the distillate with ether obtained about 0.03% of a yellow oil of strong odor, not crystallizable, decomposing on distn. even at low pressure, and having different characters from Cassan's oil. N could not be detected. The residue from the steam distn. refluxed with alc. KOH yielded about 0.15% of *camphorsmol*, C<sub>15</sub>H<sub>22</sub>O<sub>2</sub>, a yellow powder, m. 74–5°. It is an optically inactive, dihydric alc., perhaps the same as Euler's (C. A. 2, 833). *Diacylcamphorsmol*, C<sub>18</sub>H<sub>24</sub>O<sub>2</sub>(COCH<sub>3</sub>)<sub>2</sub>, flaky white crystals, m. 80°. JANET D. SCOTT

POUCHER, WM. A.: *Perfumes, Cosmetics and Soaps, with Especial Reference to Synthetics*. Vol. II. 2nd ed. New York: D. Van Nostrand Co. 406 pp. \$5. Reviewed in *Druggists Circ.* 72, 64(1928); *Perfumery Essential Oil Record* 20, 123; *Chem. Trade J.* 84, 374 (1929).

Liver oil of the basking shark (SCHMIDT-NIELSEN, SCHMIDT-NIELSEN) 27. Active glucosides from *Adonis vernalis* (FROMHERTZ) 11H. Electro-endosmosis (apparatus for treating serums) (U. S. pat. 1,711,416) 4. Basic ethers of resorcinol (U. S. pat. 1,711,020) 10. The *Camphorosma monspeliacum* of S. Cesarea (Lecce) (MAZZA, SPAGNOLO) 11D.

**Medicine.** CHEM. FAB. VON HEYDEN A.-G. (Curt Philipp, inventor). Ger. 474,689, Nov. 1, 1925. Org. medicines, normally insol. or only slightly sol. in water, are made sol. by treatment with aq. solns. of salts of alkylated, arylated or aralkylated hydroxy fatty acids. Thus, powd. thymol is warmed with a 20% aq. soln. of Na thymylhydroxyacetate, giving a 5% aq. soln. of thymol. Carvacrol is rendered sol. by Na carvacrylhydroxyacetate.

**Medicines.** FRIEDRICH PASSEK. Ger. 474,620, Feb. 4, 1927. Colloidal Au for physiol. purposes is prepd. by the action of an alkali hydroxide or silicate soln. on a soln. of a Au salt. The liquid is allowed to stand for some days and is purified centrifugally.

**Solvents for medicaments.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Ger. 474,343, Sept. 16, 1923. See Brit. 218,982 (C. A. 19, 560).

**Aqueous emulsions of medicines, insecticides, etc.** I. G. FARBENIND. A.-G. Brit. 298,823, Jan. 11, 1928. A mixt. of Turkey-red oil 40, K ricinoleate 10, paraffin oil 5-10, an alkali salt of a alkylnaphthalenesulfonic acid 3-5 and water 10-20 parts is used for forming aq. emulsions of substances such as tetrachloroethylene, eucalyptus oil or menthol for various purposes, such as fat-dissolving or greasing agents, insecticides, cosmetics, medicines or perfumery.

**Alkaloids from plant materials.** NAAMLOOZE VENNOOTSCHAP CHEMISCHE FABRIEK DELTA. Brit. 298,787, Nov. 4, 1927. The finely divided plant material may be mixed with milk of lime and is then extd. with steam counter-currentwise.

**Glucosides.** CHEMISCHE FABRIK VORM. SANDOZ. Swiss 130,021, May 23, 1927. Strongly active glucosides are prepd. from squills by extn. with org. solvents which are non-miscible with water, in presence of readily sol. salts. The ext. is evapd. *in vacuo* and washed out with fat-extg. solvent. The residue is dissolved in a mixt. of water and org. solvent and treated with insol. tannin precipitant. The filtrate is carefully evapd. to dryness, leaving the glucoside. Thus, 2 kg. squills is ground with  $\text{NaH}_2\text{PO}_4$  and  $\text{AcOEt}$ , and filtered. The filtrate is evapd. to dryness, *in vacuo* at low temps., and the residue dissolved in ether. Salicylic acid is added to ppt. the tannin, which is then filtered off. The filtrate is evapd. to give the pure glucoside.

**Glucosides.** I. G. FARBENIND. A.-G. Brit. 298,674, July 14, 1927. In obtaining water-sol. anthraquinone glucosides from drugs such as cascara sagrada or cortex frangula, the exts. are treated with a metallic hydroxide, such as freshly pptd.  $\text{Al}(\text{OH})_3$  or Fe hydroxide, to ppt. impurities.

**Cinchonine.** CHEMISCHE FABRIK VORM. SANDOZ. Swiss 130,093, Feb. 10, 1927. Addn. to Swiss 126,502. Cinchonine and cholic acid are allowed to react to produce cinchonine cholate. The substance is a powerful microbicide.

**Quinine and hydroquinone desoxycholates.** CHEMISCHE FABRIK VORM. SANDOZ. Swiss 130,091 and 130,092, Feb. 10, 1927. The desoxycholates of quinine and hydroquinone are prepd. directly by reaction with cholic acid in mol. proportions. The salts are strong microbicides. Cf. C. A. 23, 612.

**4-Aminopentene-2 and its derivatives.** I. G. FARBENIND. A.-G. (Karl Böttcher, inventor). Ger. 473,215, Mar. 28, 1925. 4-Halopentene-2 is treated with  $\text{NH}_3$  or with primary or secondary alkyl, aryl or aralkyl amines. The 4-aminopentene-2 and its derivs. so obtained are new compds. useful as *intermediates in the manuf. of drugs*. Examples are given describing the prepn. of (1) 4-diethylaminopentene-2, b. 148-151°; (2) 4-dipropylaminopentene-2, b. 182-183°; (3) 4-propylaminopentene-2, b. 145-150°; (4) pentenylaniline, b. 112°/9 mm.; (5) pentenylmethylaniline, b. 115°/7 mm.; (6) pentenyldiphenylamine, b. 190°/10 mm.; (7) pentenylbenzylamine, b. 110°/8 mm.; (8) pentenyl- $\beta$ -naphthylamine, b. 190°/10 mm.

**Phosphatide preparations.** J. D. RIEDEL-E. DE HAËN A.-G. Ger. 474,269, July 21, 1923. Stable phosphatide prepn. which are liquid at moderate temp. are prepd. by mixing the phosphatides with fats derived from acids having less than 16 C atoms in the mol. A mixt. of lecithin 2 and palm-kernel oil 1 part is mentioned by way of example.

**Bandages containing therapeutic materials in a film of cellulose gel.** WOLFF & Co., E. CZAPEK AND J. REITSTOTTER. Brit. 298,606, Oct. 12, 1927.

**Hormones.** SCHERING-KAHLBAUM A.-G. Brit. 298,610, Oct. 12, 1927. Sexual hormones are obtained from human or animal urine by extn. with an org. solvent such as ether, removal of the solvent, sapon. of the residue and isolation of the hormone from the unsaponifiable portion by treatment with a suitable solvent. Several examples are given. Cf. C. A. 23, 2252.

**Hormones.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 299,060, Oct. 20, 1927. Water-sol. and lipidol-sol. hormones are obtained separately from sexual glands by use of chem. reagents or ferments to effect hydrolysis, extn. with a water-insol. solvent such

as ether, sepg. the soln. of the lipoid-sol. hormone thus obtained and recovering the water-sol. hormone from the aq. fraction. Various details of procedure are described. Cf. C. A. 23, 2786.

**Drying biological products.** MARIUS E. POZZI-ESCOR. Fr. 648,359, June 18, 1927. The N escaping from liquid-air rectifying columns is used for drying exts. from organs, scrums, vaccines, etc.

**Disinfectants and germicides.** ELEKTRO-OSMOSE A.-G. (Graf Schwerin Gesellschaft). Fr. 648,749, Dec. 8, 1927. A strongly disinfectant or germicidal soln. is obtained by adding 0.85% of NaCl, KCl, CaCl<sub>2</sub>, or NaHCO<sub>3</sub> to solns. of acids, bases or salts such as HCl, NaOH, Na<sub>2</sub>CO<sub>3</sub>, Na<sub>2</sub>PO<sub>4</sub>, the concn. of which is below 1/50 N. The above salts may be replaced by small amts., ineffective in themselves, of AgNO<sub>3</sub>, derivs. of acridine, salts of Cu or Hg to increase the action of the acids or bases.

**Apparatus for treating tobacco with air currents.** UNITED CIGARETTE MACHINE CO. A.-G. Brit. 299,039, Oct. 20, 1927.

**Cosmetics.** PIETER GOENEE. Ger. 474,690, Sept. 10, 1926. A body powder is prepd. by mixing stable org. peroxides, such as benzoyl peroxide, with a weakly alk. substance such as Ca<sub>3</sub>(PO<sub>4</sub>)<sub>2</sub>.

## 18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

**Recent developments in the manufacture of sulfuric acid.** S. F. SPANGLER. Chem. Construction Co., Charlotte, N. C. *Ind. Eng. Chem.* 21, 417-21 (1929).—Recent increases in the demand for H<sub>2</sub>SO<sub>4</sub> have been for higher strengths, making the contact process relatively more important. Developments in the chamber process mentioned include NH<sub>3</sub> oxidation, and intensive methods of working. In the concn. of weak acid, the drum type of concentrator is described. In the contact process, the chief developments have been the use of V catalysts, in specially designed converters, and the burning of molten S with pre-dried air.

T. H. CHILTON

**The preparation of selenic acid and its salts.** ERNEST R. HUFF AND C. R. McCROSKY. Syracuse Univ. *J. Am. Chem. Soc.* 51, 1457-8 (1929).—SeO<sub>2</sub> was refluxed 2 hrs. with 30% H<sub>2</sub>O<sub>2</sub>, giving 90% of the theoretical yield of H<sub>2</sub>SeO<sub>4</sub>. Selenates of Cu, Ni, Co, Al and Mg also were prepd. There are 11 references. G. M. P.

**Stainless-iron nitric acid equipment.** W. M. MITCHELL. *Ind. Eng. Chem.* 21, 442-5 (1929).—The manuf. of stainless iron for equipment used to make HNO<sub>3</sub> from NH<sub>3</sub> is discussed. About 500 tons has been used for this purpose since 1923.

G. B. TAYLOR

**Preparation of a solution containing phosphoric acid direct from bone ash for the impregnation of match sticks to render them non-glowing.** R. L. DATTA AND T. BASU. Dept. Industries, Bengal, *Bull.* 27, 6 pp. (1928).—The sticks are impregnated with a soln. contg. P<sub>2</sub>O<sub>5</sub> obtained by extg. 3 pts. of bone ash with 3 pts. of com. H<sub>2</sub>SO<sub>4</sub> (d. 1.55). A suitable d. for this soln. is 1.035; it then contains 3.78% P<sub>2</sub>O<sub>5</sub> and 0.19% H<sub>2</sub>SO<sub>4</sub>, of which 0.05% is free acid. This free acid turns the splints brown but neutralizing the acid with NH<sub>3</sub> soln. overcomes this defect where necessary. B. C. A.

**Poupin process (extraction of sodium nitrate).** DELCOURT, B. PINILLA, J. LATORRE AND J. BANCELIN. *Caliche* 10, 299-311 (1928).—Official Chilean reports on a 4-month expt at Oficina Iberia. A small works plant was made by raising the false bottom of a Shanks process leaching tank to 1 m. and replacing its vertical row of steam coils by 2 systems of horizontal coils under the false bottom, one under each half. The leaching tanks were not connected with each other. Caliche was reduced by jaw and gyratory crushers to 1 in. Screened charge was placed at the bottom, then unscreened, then fines. Hot concd. liquor was withdrawn from the bottom when of desired d. Treating liquor was heated in interchangers, stored in concentric tanks, then sprayed over the charge intermittently, first mother liquor at 60°, then dil. washes at 60°, 50° and 35°, resp., and finally water at 30-40°. The fines accumulating under the false bottom were withdrawn between charges. Recovery was about 80% (Shanks, 50-60%), discharged ripio, about 2 1/4% NaNO<sub>2</sub> (Shanks, 6-8%); fuel and installation somewhat less than in the Shanks process; evapn. loss 730 l. (Shanks 900 l.)/ton NaNO<sub>3</sub> obtained. The time of treatment was limited by the rate of heat penetration of charge. Improvement was attributed to intermittent application of liquids. J. H. F.

**Removal of ferrous chloride from solutions of commercial zinc chloride.** N. N. EFREMOV AND A. M. ROZENBERG. Severochem. *J. Chem. Ind. (Moscow)* 5, 1280-2, 1431-4 (1928).—FeCl<sub>2</sub>, which usually contaminates com. solns. of ZnCl<sub>2</sub>, is a trouble-

some impurity, as it tends slowly to oxidize continually, forming a brown ppt. The best means of removing  $\text{FeCl}_2$  from  $\text{ZnCl}_2$  solns. is by pptn., using an oxidizing agent. Tests were made with various oxidizing agents to find the best one.  $\text{Cl}$  gas acts at first very energetically, but the action slows down gradually as the  $\text{FeCl}_2$  content decreases.  $\text{Cl}$  only acts at the rate at which it dissolves; therefore, to avoid considerable losses of  $\text{Cl}$ , a slow current of the gas and very good stirring must be used. After the operation the dissolved  $\text{Cl}$  may be removed by blowing in air, or better by heating. The use of  $\text{Ca}(\text{ClO})_2$  is very effective, but it introduces  $\text{CaCl}_2$  instead of  $\text{FeCl}_2$ . To remove  $\text{CaCl}_2$  it has been proposed to treat the soln. by  $\text{ZnSO}_4$ :  $\text{CaCl}_2 + \text{ZnSO}_4 \rightleftharpoons \text{CaSO}_4 + \text{ZnCl}_2$ . The objection is that it is a reversible reaction and that it is not easy to remove  $\text{CaSO}_4$  which, in the presence of  $\text{ZnCl}_2$ , has a considerable soly. in  $\text{H}_2\text{O}$ . Oxidation by  $\text{MnO}_2$  is effective only in acid solns. and requires heating. If an excess of  $\text{HCl}$  is used,  $\text{Cl}$  is omitted and poisons the atm. Another disadvantage is the formation in the soln. of  $\text{MnCl}_2$ , which can only be pptd. by  $\text{Cl}$  as  $\text{MnO}_2$ .  $\text{KClO}_3$  acts theoretically according to the equation  $6\text{FeCl}_2 + \text{KClO}_3 + 6\text{HCl} = 3\text{H}_2\text{O} + \text{KCl} + 6\text{FeCl}_3$ , but in reality much less  $\text{HCl}$  is used up than would appear from this equation. There is no need of adding  $\text{HCl}$ , on account of the reaction  $\text{ZnCl}_2 + 2\text{H}_2\text{O} \rightleftharpoons \text{Zn}(\text{OH})_2 + 2\text{HCl}$ ;  $\text{Zn}(\text{OH})_2$  formed soon disappears because of the reaction  $3\text{Zn}(\text{OH})_2 + \text{Fe}_2\text{Cl}_6 \rightleftharpoons 3\text{ZnCl}_2 + \text{Fe}_2(\text{OH})_6$ . An excess of  $\text{KClO}_3$  is not needed. The soln. must be boiled some time after introducing  $\text{KClO}_3$ . The advantage of this method is that it only introduces a little  $\text{KCl}$  into the soln.; the disadvantage is that it requires boiling the soln. for some time. Oxidation by  $\text{HNO}_3$  is extremely slow and incomplete, unless either prolonged boiling or addn. of  $\text{HCl}$  is practiced. Even a prolonged current of air passed through the soln. oxidizes but an insignificant quantity of  $\text{FeCl}_2$ . The use of  $\text{H}_2\text{O}_2$  gives excellent results, but the reagent is too expensive. Electrolytic oxidation is the best and cheapest method. Const. stirring should be practiced, particularly in the anode zone, to avoid volatilization of  $\text{Cl}$ . The electrolyte must not contain an excess of acid to avoid electrolysis of  $\text{ZnCl}_2$ .

BERNARD NELSON

Extraction of bromine and iodine by solvents. III. Extraction of iodine. B. G. PANTELEIMONOV. *J. Chem. Ind. (Moscow)* 5, 1220-7(1928); cf. *C. A.* 22, 4731.—The extn. of  $\text{I}$  by kerosene, benzine or vaseline is similar to that of  $\text{Br}$ . When extg.  $\text{Br}$  the solvent power of kerosene becomes great only when  $\text{Br}$  (or even  $\text{Cl}$ ) compds. accumulate in it; with  $\text{I}$ , the dissolving power of kerosene decreases considerably with the accumulation of  $\text{I}$  compds. in soln.  $\text{I}$  forms with kerosene a certain quantity of a compd. not sol. in  $\text{H}_2\text{O}$  or in kerosene. The effects of time, light and temp. on extn. are the same with  $\text{I}$  as with  $\text{Br}$ . With increase of temp. the quantity of  $\text{HI}$  formed decreases as the surface tension weakens.  $\text{HI}$  is not formed during the extn. to the same extent as  $\text{HBr}$ .

BERNARD NELSON

Bleaching earths. L. KALUSKY. *Seifensieder-Ztg.* 56, 18-9, 27-8, 34-5, 43-4, 52-3, 58-9, 71-2, 80-1, 87-8, 96-7(1929).—The bleaching power of earths depends upon the interstices left in minerals when one or more of their constituents are removed by weathering,  $\text{H}_2\text{O}$  or heat. Brucite, koenenite, briotite and zeolites are examples of minerals which lose part or all of their base, with part substitution by other bases or by  $\text{H}_2\text{O}$ . When hydrated they form those natural deposits of bleaching earths that cannot be improved by treatment. If part of the hydrate  $\text{H}_2\text{O}$  has again been replaced by a base, the latter can be improved by treatment. Active earths are hygroscopic up to 31.21%;  $\text{CaCl}_2$  in *vacuo* reduced the  $\text{H}_2\text{O}$  to 0.45%. The dried earths also absorbed some of the fat used for lubricating the desiccator. Chem. compn. is no criterion for bleaching quality. Purification usually removes all  $\text{CaO}$  and some  $\text{Mg}$  and alkalies. Even by eliminating  $\text{H}_2\text{O}$  and loss by ignition from the calcn., no chem. compn. could be formulated that would predict bleaching quality. The criterion is the shape of the skeleton left behind. Some 37 analyses of earths are tabulated (sources not stated) and 7 are compared in compn. before and after processing. Removal of oxides by treatment causes a corresponding increase in  $\text{SiO}_2$ , which, reduced to a dry basis, permits the calcn. of shrinkage by purification. By use of the ratio of %  $\text{SiO}_2$ : % sesquioxides: % loss by ignition K. shows that those earths which bleach different oils markedly differently, show a high sesquioxide no. and a correspondingly high loss on ignition. The ratio  $\text{SiO}_2$ : sesquioxides varies in raw earths between 1:0.479 and 1:0.615, while the purified earths vary between 1:0.169 and 1:0.888, indicating in some cases an excessive removal of oxides during treatment. One foreign earth in the raw state decolorized the easily bleached soy-bean oil 72.01% and in the purified state 88.65%. The raw earth contained 17.88%  $\text{CaO}$ , equal to 31.93%  $\text{CaCO}_3$ . Mineral oil was bleached better by this raw earth than by the purified earth, indicating that the removal of  $\text{CaCO}_3$  destroyed the fine interstitial structure of the original earth, diminishing its bleaching

power. Results with soy-bean oil, linseed oil and mineral oil are tabulated; the bleaching power is expressed in % by the Lovibond tintometer, both % total color and % individual red and yellow. Two % of prep'd. earths removed from soy-bean oil at 90° in 20 mins. 73.34–88.63% color; from linseed oil at 95° in 30 mins. with 4% earth 23.83–73.26%, and from mineral oil at 90° in 30 mins. with 5% earth 13.49–66.01%. Addn. of CaO for neutralization is detrimental; earths so treated lose some bleaching power when moist, while properly prep'd. earths regain their full power when dried after moistening. Well-made earths stand a temp. of 400° without loss of bleaching power.

P. E.

The problem of determining the bleaching power of fuller's earth. E. SCHILD. *Seifensieder-Ztg.* 56, 86–7(1929).—The present comparative methods of bleaching an unknown oil with a "standard earth" of known effect or of bleaching a "standard" oil with the unknown earth lead to erroneous results, since both standards are subject to aging, involving a change in the supposed standard of comparison. The Lovibond tintometer works best for abs. color detns., while the Duboscq and the Autherried colorimeters are better suited for relative color detns.

P. ESCHER

Infusorial earth from Lüneburger Heide. W. PRYER. Halle a/Saale. *Apoth. Ztg.* 44, 448(1929).—The occurrence of infusorial earth at 4 points in this heath is discussed in connection with the mining and refining operations incidental to its production. The phys. characters of the crude and calcined products are, resp.: appearance, gray to greenish, gray to rose or nearly white; smell, peculiarly strong, ditto; moisture, 7.6, 6.0%; d. (in alc. after elimination of air) 1.85, 2.25; ash, 70.4, 93.6%; insol. in 10% HCl, 85.5, 92.5%; H<sub>2</sub>O-sol., 4.3, 4.7%; EtOH-sol., 3.2, 3.0%; Et<sub>2</sub>O-sol., 1.4, 0.4%; adsorption capacity —, about 20; SiO<sub>2</sub>, 68.2, 91.4%; N substance (0.95% N) = 5.93%. During the 30 Years' War, as also in 1719 and 1733 (and even today in Sweden and Finland) kieselguhr was and is used in bread.

W. O. E.

Bleaching of gangwa wood (*Excoecaria agallocha*) in the manufacture of matches. R. L. DATTA AND T. BASU. Dept. Industries, Bengal. *Bull.* 18, 6 pp.(1928).—In the bleaching of gangwa wood so as to render it suitable for match splints, a cold, alk. aq. soln. of bleaching powder contg. 0.20% of available Cl gave the best results. Boiling with water or treatment with H<sub>2</sub>SO<sub>4</sub> or KMnO<sub>4</sub> soln. was unsuitable.

Iodine extract from sponges. WILHELM HARGELE. Ger. 474,820, June 26, 1926. An alc. ext. of I is obtained from bath sponges by steeping them in inorg. base solns. and extg. with alc.

Hydrochloric acid. LOUIS TOCCO. Fr. 649,930, Aug. 3, 1927. Chlorides such as CaCl<sub>2</sub>, MgCl<sub>2</sub>, BaCl<sub>2</sub>, NaCl and KCl are treated at a sufficiently high temp. with H for the production of HCl, the hydrides of the metals being formed. For NaCl, KCl and MgCl<sub>2</sub> the temp. should be above 700°, and for CaCl<sub>2</sub> and BaCl<sub>2</sub> above 900°.

Hydrocyanic acid. P. T. DOLLEY (to Calif. Cyanide Co.). Brit. 299,019, Oct. 19, 1927. HCN is formed by treating with steam (to which CO<sub>2</sub> or SO<sub>2</sub> may be added) dry powd. cyanogen compds. of alkali or alk. earth metals (such as the compd. produced by melting Ca cyanamide with NaCl). An app. is described.

**Phosphoric acid.** SOC. DES PHOSPHATES TUNISIENS. Fr. 649,497, Feb. 11, 1928. Phosphoric acid is recovered from gases coming from the fusion of phosphatic materials by passing the gases through a granular filtering layer, then either removing the acid by a current of air passed through the filter, or using the filter contg. the acid as a charge for the furnace.

**Production of phosphoric anhydride and its derivatives.** G. TABOURIN and G. BRACO. Belg. 353,251, Oct. 31, 1928.  $\text{Ca}_3(\text{PO}_4)_2$  minerals are treated at high temp. with  $\text{SiO}_2$  and coal, the latter acting only as fuel and being burned in an oxidizing atm. Forced draft is used so as to fuse the silicate slag and remove the volatilized  $\text{P}_2\text{O}_5$ .

**Sulfuric acid.** THE SELDEN CO. Fr. 649,525, Feb. 16, 1928.  $\text{SO}_2$  is oxidized to  $\text{SO}_3$  by passing  $\text{SO}_2$  and O at reaction temp. over a contact mass contg. a catalytically inactive base-exchange substance, siliceous or not, physically combined with an active catalytic diluent preferably as a homogeneous structure. Stabilizers and stabilizer promoters may be mixed or combined with the base-exchange substance. The catalytically active constituents may be vanadates of Fe, Ag, Mn, Cu, Ti, Co or Ni. Several examples are given. Fr. 649,526 describes a similar contact process for  $\text{H}_2\text{SO}_4$  in which  $\text{SO}_2$  and O are passed at a high temp. over a contact mass contg. at least one non-siliceous, catalytically active base-exchange substance, dild. or not, in which at least one catalytically active constituent is chemically combined in or with the base-exchange substance in an exchangeable or non-exchangeable form, with or without the presence of stabilizers or stabilizer promoters chemically combined or physically assocd. with it. At least part of the dild. substance may be a non-siliceous or zeolitic base-exchange substance. The principal catalytically active element in the contact mass is V.

**Sulfur oxides.** CHARLES S. ROBINSON. Ger. 474,925, May 23, 1925. See Brit. 239,252, C. A. 20, 2051.

**Nitric oxide.** ELEKTRIZITÄTWERK LONZA. Ger. 473,601, May 1, 1927. See Brit. 289,412 (C. A. 23, 676).

**Solid carbon dioxide.** DRYICE CORP. OF AMERICA. Brit. 298,792, Nov. 15, 1927. Large blocks of solid  $\text{CO}_2$  of high density are obtained by freezing the liquid under a pressure of 1500-2500 lbs. per sq. in. and continuously pumping the liquid into the freezing chamber during freezing to compensate for contraction. An app. is described in which  $\text{CO}_2$  from flue gases may be sep'd. and used.

**Silicic acid esters.** I. G. FARBENIND. A.-G. Brit. 298,778, Oct. 24, 1927. Production of silicic acid esters by interaction of  $\text{SiCl}_4$  and alcs. such as EtOH, MeOH or benzyl alc. is effected in the presence of inert diluents such as  $\text{C}_6\text{H}_6$ , which avoids the need of dehydrating the alcs.

**Ammonia.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Fr. 648,458, Feb. 6, 1928. In the prepn. of  $\text{NH}_3$  from coke-oven gas or other gaseous mixts. of like compn., the gas is carefully freed from substances such as CO,  $\text{CH}_4$ , etc., which would hinder the reaction and after the synthesis and elimination of the  $\text{NH}_3$  formed, the residual gases are only taken into the reaction mixt. after the latter has passed through the liquefying plant. Purification of the gas may be assisted by treating it with liquid N.

**Synthesis of ammonia.** HANS HARTER. Fr. 648,434, Feb. 4, 1928. To produce exothermic reactions between gases, particularly in the synthesis of  $\text{NH}_3$  under high pressure, the entrance of gas is divided and the inflow of gases is uniformly spread over the length of the contact tube so that contact tubes as long as possible may be used. The tube may be divided into sep. compartments. Cf. C. A. 23, 1222.

**Synthesis of ammonia.** MARIA CASALE SAACHI. Fr. 648,844, June 8, 1927. A mixt. of H and N for the synthesis of  $\text{NH}_3$  is prepd. by incompletely burning hydrocarbons in the presence of steam with O obtained by the distn. of liquid air; the mixt. of gases thus obtained with added steam is catalyzed to convert CO into  $\text{CO}_2$ , and cooled to eliminate  $\text{CO}_2$ , and N from the liquid air distn. is then added.

**Bromides.** JOHANNES H. VAN DER MEULEN. Fr. 649,329, Feb. 20, 1928. See Brit. 285,915 (C. A. 23, 244).

**Metal chlorides.** R. B. GOLDSCHMIDT. Belg. 353,967, Oct. 31, 1928. Finely ground ores, rocks or metal compds. in suspension in a suitable liquid are treated with Cl, and the films of chlorides formed on the metallic particles are removed as they are formed, either mechanically or by dissolving.

**Metal polysulfides.** IGNAZ KREIDL. Austrian 112,335, Oct. 15, 1928. Addn. to 93,927. Austrian 93,927 describes the manuf. of polysulfides of the alk. earth metals, As, Pb and Cu by heating the corresponding oxides, hydroxides or sulfides at about  $100^\circ$  with S in the presence of a S-contg. catalyst, e. g., an alkali sulfite, sulfide, or thio-sulfate and, if desired, of small amts. of water. This method is now modified by adding

in addn. to water, a stable hygroscopic substance such as glycerol in sufficient amt. to form a paste.

**Molybdates.** I. G. FARBENIND. A.-G. Ger. 473,991, Apr. 7, 1925. Molybdates of the alk. earths and heavy metals, especially Ca, are prepd. by heating to bright redness roasted molybdenite with the oxide of the metal whose molybdate is desired. Instead of the oxide, an oxide-yielding compd. of the metal, such as  $\text{CaCO}_3$ ,  $\text{FeCO}_3$ , or caustic lime may be used.

**Nitrates.** JEGOR BRONN, CONCORDIA BERGBAU A. G. and GEORG FISCHER. Fr. 650,030, Jan. 10, 1928. Nitrates, particularly of K and Na, are obtained by treating the corresponding chlorides with vapors of  $\text{HNO}_3$  in the presence of a large amt. of steam (10–15 times the wt. of  $\text{HNO}_3$  vapors). The lumps of salt used may be sprayed with a salt soln. during the reaction.

**Alkali oxides.** DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Ger. 473,832, June 9, 1925. In the prepn. of oxides of the alkali metals by the action of O, or O-contg. gases such as air, on the metals at high temps., the metal is mixed with a considerable excess of diluent and treated with the oxidizing gas with agitation as in a rotary furnace. The diluent may be alkali oxide.

**Oxide mixtures.** I. G. FARBENIND. A.-G. (Alwin Mittasch, Richard Lucas and Robert Griessbach, inventors). Ger. 474,416, Jan. 9, 1925. Addn. to 422,269. Finely divided and intimate mixts. of  $\text{Fe}_2\text{O}_3$  with other oxides, such mixts. being useful, *e. g.*, as *catalysts* and *pigments*, are prepd. by the combustion of mixts. of  $\text{Fe}(\text{CO})_5$  with other suitable elements or compds. Such addnl. substances may be volatile and oxidizable, *e. g.*, other carbonyls, organo-metallic compds.,  $\text{CrO}_2\text{Cl}_2$ , or  $\text{SiCl}_4$ , or they may be non-volatile, non-oxidizable substances, *e. g.*,  $\text{Bi}_2\text{O}_3$  or  $\text{Al}_2\text{O}_3$ , added in gaseous suspension. Examples are given.

**Alkaline earth salts.** SOC. MINIERE "LA BARYTINE." Fr. 649,928, Aug. 3, 1927. Alk. earth sulfates are converted into sol. salts such as chlorides, bromides, etc., by passing a current of HCl or HBr on to the sulfate heated to redness, the  $\text{SO}_4$  displaced being recovered in water or  $\text{H}_2\text{SO}_4$ ; or steam may be passed over a mixt. of the sulfate and NaCl heated to redness, giving a mixt. of the alk. earth chloride and NaOH.

**Calcining alkaline earth carbonates.** WALLER CROW (to Dittlinger-Crow Co.). U. S. 1,710,967, April 30. Materials such as calcite and magnesite are first subjected to superheated steam of a pressure of about 100 lbs. per sq. in. and a temp. of about  $320^\circ$  and then to the action of air heated to a temp. sufficiently high to decompose the hydroxide formed by the action of the superheated steam.

**Separating alkaline earth phosphates.** T. BENCKISER, A. REIMANN and A. REIMANN (trading as the Firm of J. A. Benckiser) and F. DRAISBACH. Brit. 298,436, Feb. 21, 1928. Crude phosphates are treated with  $\text{H}_2\text{SO}_4$  and the soln. is neutralized (suitably with  $\text{Na}_2\text{CO}_3$ ) to form a monophosphate soln. contg. some alk. earth monophosphates which may be converted into di-alk. earth phosphates by adding a suitable excess of di-alkali phosphate and heating in an autoclave to  $150\text{--}200^\circ$  under 5–15 atm. pressure. The di-alk. earth phosphates are pptd. in readily filterable form and are easily sep'd., leaving a mono-alkali phosphate soln.

**Colloidal metal silicates.** MARIA GRÄFIN. Ger. 474,501, Dec. 18, 1925. Highly coned colloidal metal silicate solns. are prepd. by treating a metal salt soln. with water glass, with a non-electrolyte, such as glycerol, as the dispersion agent. Thus, powd.  $\text{CuSO}_4$  is ground with  $\text{Na}_2\text{SiO}_3$  and glycerol. After standing for some time, a deep blue soln. of colloidal  $\text{CuSiO}_3$  is obtained and a gel-like residue remains at the bottom. Other examples are given.

**Alumina.** ELEKTIZITÄTSWERK LONZA. Swiss 130,145, Aug. 4, 1927. Fused alumina is finely divided by rapid cooling, as by spraying into water.

**The simultaneous production of pure alumina and pure carbon dioxide.** C. D'ASSEVE. Belg. 354,141, Oct. 31, 1928. A soln. of crude  $\text{Al}_2(\text{SO}_4)_3$  is treated with a soln. of  $\text{Mg}(\text{HCO}_3)_2$ , causing evolution of  $\text{CO}_2$ . The pptd. basic Fe and Al carbonates are heated, evolving pure  $\text{CO}_2$  and yielding Fe and Al hydroxides; these are treated with a hot NaOH soln. The Na aluminate is treated with the  $\text{CO}_2$  evolved in the 1st reaction.

**Alumina, potash, etc.** "MONTECATINI" SOC. GÉNÉRALE PER L'IND. MINERARIA ED AGRICOLA. Fr. 649,503, Feb. 13, 1928.  $\text{Al}_2\text{O}_3$  and K salts are obtained by treating rocks contg. silicates of Al and K with  $\text{HNO}_3$  of medium concn. The nitrates obtained are dried and the  $\text{HNO}_3$  is recovered by dry distn.

**Baryta.** VICTOR PIVERT. Fr. 649,732, July 19, 1927. Natural baryta is wholly converted to com. extra-white baryta by adding the granulated baryta to an acid soln.,

e. g., HCl, H<sub>2</sub>SO<sub>4</sub>, or HF if the baryta contains quartz, heating to a moderate temp. in thin layers until it becomes a saffron-yellow, pptg. in water and washing.

**Purifying ammonium bicarbonate.** GES. FÜR KOHLENTCHNIK M. B. H. (Wilhelm Glud and Wilhelm Riese, inventors). Ger. 474,082, Sept. 12, 1928. See Can. 281,357 (C. A. 22, 3024).

**Beryllium oxide.** ROBERT C. PRICE and HUGH S. COOPER (to Beryllium Corp. of America). U. S. 1,710,840, April 30. A mineral such as beryl is heated with a flux contg. a Ca compd. such as lime and CaF<sub>2</sub>; H<sub>2</sub>SO<sub>4</sub> is added to the resulting product; the sulfate produced is dissolved in water, evapd. to a d. of about 1.31, pptd. CaSO<sub>4</sub> is sepd., and sulfates of Be and Al are sepd. and calcined.

**Separation of calcium chloride from calcium hypochlorite.** THE MATHIESON ALKALI WORKS. Ger. 473,925, May 24, 1927. The hypochlorite is treated with an alkali hypochlorite. Thus, 47 parts NaOCl and 73 parts water are mixed with 500 parts of filter cake contg. about 50.1% Ca(OCl)<sub>2</sub>, 6.9% CaCl<sub>2</sub>, 5.7% Ca(OH)<sub>2</sub>, 0.3% NaCl and 37% water. The mixt. is well stirred and dried without pressing. The product contains less than 0.5% CaCl<sub>2</sub>.

**Calcium hypochlorite.** THE MATHIESON ALKALI WORKS. Ger. 473,924, May 24, 1927. Ca(OCl)<sub>2</sub> is freed from CaCl<sub>2</sub> by treating it with an amount of caustic alkali equivalent to the CaCl<sub>2</sub> content. Thus, 200 parts of filter cake contg. Ca(OCl)<sub>2</sub> and about 20 parts CaCl<sub>2</sub> are treated with 14.4 parts NaOH and 11 parts water, well mixed, and dried.

**Calcium hypochlorite.** THE MATHIESON ALKALI WORKS. Ger. 473,975 and 473,976, May 24, 1927. Ca(OCl)<sub>2</sub> is prepd. by chlorinating lime in the presence of water and an alkali compd. Thus, milk of lime is mixed with an equiv. amt. of NaOH and chlorinated. Ca(OCl)<sub>2</sub> is also prepd. by chlorinating a soln. of caustic alkali and mixing the alkali hypochlorite with CaCl<sub>2</sub>.

**Calcium hypochlorite.** THE MATHIESON ALKALI WORKS. Ger. 474,080, May 24, 1927. A mixt. of Ca(OH)<sub>2</sub> with NaOH in excess is chlorinated in the presence of water, and the chlorinated mass is treated with sufficient CaCl<sub>2</sub> to react with the NaOCl. A stable mixt. of Ca(OCl)<sub>2</sub> with NaCl is obtained on drying.

**Calcium hypochlorite.** THE MATHIESON ALKALI WORKS. Ger. 474,220, May 24, 1927. An aq. suspension of an excess of Ca(OH)<sub>2</sub> in caustic alkali soln. is chlorinated and the Ca(OCl)<sub>2</sub> then sepd. The sepn. may be effected by filtering and pressing, or by filtering and treating with NaOCl, or by treating with NaOCl and then filtering. Ca(OCl)<sub>2</sub> free from CaCl<sub>2</sub> is so obtained.

**Cobalt carbonyl.** I. G. FARBERIND. A.-G. Brit. 298,714, July 28, 1927. The process of prepg. Fe carbonyl described in Brit. 250,132 (C. A. 21, 994) is applied to the prepn. of Co carbonyl. CO or a gas contg. it is passed under pressure over metallic Co (which may be prepd. by reduction of Co oxide or Co ores with H) and the Co carbonyl is sepd. by cooling before releasing the pressure. Various details are given.

**Iron oxide.** I. G. FARBERIND. A.-G. Brit. 298,926, July 14, 1927. In order to produce finely divided Fe oxide, Fe(OH)<sub>3</sub> is heated under pressure in the presence of water to 110–150°. A ferric salt such as FeCl<sub>3</sub> may be heated with lime, chalk or Na<sub>2</sub>CO<sub>3</sub> in an autoclave, and the product filtered, washed and dried. Oxides ranging in color from yellowish red to dark violet are obtained. Cf. C. A. 23, 245.

**Potassium nitrite.** GEWERKSCHAFT SACHTLEREN and HERMANN PÖTZER. Ger. 472,605, Sept. 12, 1926. KNO<sub>2</sub> is recovered from Fischer's salt in the sepn. of Co and Ni in soln. The ppt. obtained is melted with caustic alkali and the CoO in the smelt sepd. from the sol. part. Thus, a soln. of CoSO<sub>4</sub> and NiSO<sub>4</sub> is mixed with KNO<sub>3</sub> and stirred. The pptd. K cobaltinitrite is filtered off, mixed with caustic alkali and heated until it melts. The mass is treated with water and the CoO sepd.

**Separating sodium sulfate from sulfuric acid.** VEREINIGTE GLANZSTOFFFABRIKEN A.-G. Brit. 298,639, Oct. 13, 1927. In regenerating coagulating baths for viscose or other operations, sepn. of Na<sub>2</sub>SO<sub>4</sub> from H<sub>2</sub>SO<sub>4</sub> is effected by concg. the soln., preferably to an acid content of about 75–80%, cooling and sepg. the crystd. salt.

**Freezing mixture comprising ammonium nitrate and crystallized soda.** L. A. GARCHÉY and B. GARCHÉY. Brit. 298,623, Oct. 14, 1927. These substances are mixed with each other and with water at the time of use.

**Hydrogen.** JOHN S. BEEKLEY (to Lazote, Inc.). U. S. 1,711,036, April 30. A mixt. of steam and a gaseous hydrocarbon such as CH<sub>4</sub> is submitted to the action of a heated catalyst (suitably a Ce-Ni catalyst at a temp. of about 500°) together with an addn. of O and a reducing gas such as recirculated gas already treated which serve to check loss of activity of the catalyst. Cf. C. A. 23, 1225.

**Hydrogen.** L'OXHYDRIQUE FRANÇAISE. Fr. 649,724, July 18, 1927. See Brit. 294,110. (C. A. 23, 1999).

**Hydrogen from mixed gases.** I. G. FARBENIND. A.-G. Brit. 299,167, Sept. 29, 1927. Pure H is recovered from mixts. such as those also contg. CH<sub>4</sub> by scrubbing the mixts., at temps. below -60° (and preferably under high pressure, suitably about 50 atm.) with benzines which do not freeze under such conditions. The recovered H is free from catalyst poisons such as ether, CO, H<sub>2</sub>S and CS<sub>2</sub>.

**Hydrogen and carbon monoxide.** I. G. FARBENIND. A.-G. Fr. 649,296, Nov. 14, 1927. A mixt. of H and CO is obtained by introducing gaseous hydrocarbons or gases contg. them tangentially into a vessel and adding O or gases contg. it, preferably also tangentially to the circulating gases with a view to their partial combustion.

**Hydrogen and sulfur.** WERSCHEN-WEISSENFELSER BRAUNKOHLN A.-G. Ger. 473,770, Jan. 14, 1927. H and S are prepd. from iron pyrites from which the total S has not been extd. during smelting, by passing steam over the heated material. Half the S may be removed by distn. and the raw material then heated and subjected to the action of the steam.

**Colloidal sulfur.** I. G. FARBENIND. A.-G. (Fritz Winkler and Fritz Giller, inventors). Ger. 472,913, Nov. 29, 1927. Addn. to Ger. 358,700. Colloidal or highly dispersed S is prepd. by allowing yellow (NH<sub>4</sub>)<sub>2</sub>S<sub>2</sub> soln. mixed with a protective colloid to flow down the inner walls of an upright or inclined tube and exposing the mixt. to the action of a current of steam.

**Dissociating sulfur vapor.** I. G. FARBENIND. A.-G. Brit. 298,599, Oct. 12, 1927. See Ger. 468,506 (C. A. 23, 1226).

**Iodine from crude sodium nitrate.** I. G. FARBENIND. A.-G. Brit. 298,670, July 14, 1927. Crude Na nitrate is heated to 200-250° to liberate free I, which vaporizes and is condensed. The process may be facilitated by use of a current of gas or vapor such as SO<sub>2</sub>, NO, air or water vapor. The residual material may be heated to a higher temp. to form N oxides as described in Brit. 266,744 (C. A. 22, 848) or may be treated by leaching or otherwise to sep. the nitrate.

**Oxygen.** GEORG LESCHIK. Swiss 130,403, June 27, 1927. See Fr. 636,108 (C. A. 23, 245).

**Phosphorus.** SOC. ANON. DES CHARBONS ACTIFS ÉDOUARD URBAIN. Fr. 649,937, Aug. 4, 1927. P is extd. from gaseous mixts. contg. it by means of active charcoal at a temp. of 150-200°. The P is recovered from the charcoal by steam at a temp. of 200-350°.

**Active carbon.** SOC. ANON. DES CHARBONS ACTIFS ÉDOUARD URBAIN. Fr. 649,746, July 20, 1927. See Brit. 294,214 (C. A. 23, 2000).

**Active carbon.** VEREIN FÜR CHEMISCHE UND METALLURGISCHE PRODUKTION. Fr. 648,709, Feb. 13, 1928. See Brit. 285,386 (C. A. 22, 4738).

**Gas carbon.** IMRE SZARVASY. Ger. 474,081, May 1, 1928. The thermal decompn. of CH<sub>4</sub> or natural gas to produce a graphitic C and soot is conducted in the presence of soot obtained in a preceding operation, the soot being compressed to suitable shapes and fed to the reaction chamber. It is then found that the graphitic C deposits on the compressed soot, which also is converted to a like product, while the soot newly generated in the decompn. passes away with the residual gases. This soot is sepd., compressed, and used in the next decompn. step.

**Active masses.** I. G. FARBENIND. A.-G. Fr. 649,826, Feb. 25, 1928. Active masses contg. C are made by mixing irreversible colloids and addnl. substances which may be charcoal, particularly activated, or substances contg. charcoal or capable of being carbonized but with the exception of carbonizable substances still having a cellular structure. If the colloid is used in the form of a sol, carbonizable substances having a cellular structure may be used provided the sol is taken in amt. more than necessary to imbibe them. The mixts. after elimination of liquid are submitted to mech. treatment such as grinding, beating, malaxing, etc.

**Adsorbent agents.** I. G. FARBENIND. A.-G. Fr. 649,794, Feb. 24, 1928. See Ger. 469,653 (C. A. 23, 1728).

**Carbonaceous adsorption material.** O. SCHÖBER. Brit. 298,546, June 9, 1927. An adsorption agent contg. at least 10% free C and over 20% (e. g., 30-40%) of ash sol. in HCl is formed from starting materials such as coal, brown coal, peat or coke with oxidizing gases or vapors such as O or air which may be admixed with combustion gases, steam, CO<sub>2</sub>, N or Cl. Numerous details of the activation process are given and an app. is described. The process may be carried out in either a continuous or a non-continuous manner, and the app. used may also be used for regenerating used activated material. S and P may be removed by passing the activated material through

a magnetic field in which the Fe compds. of S and P are retained. Fe may be added if necessary to facilitate this operation. Sulfides and phosphides may also be removed by use of acids or acid salts or  $\text{CO}_2$ . The product may be sepd. by a powerful magnetic field into fractions having different ash contents in one of which fractions the S- and P-contg. impurities may be concd. for further purification. Cf. C. A. 22, 4739.

**Adsorbent for separating gases and vapors.** C. F. BOEHRINGER & SOEHNE, G. M. B. H. and E. WILKE. Ger. 473,783, Nov. 4, 1924. Gases and vapors are extd. from mixts. by the employment of a gel of  $\text{H}_2\text{SiO}_3$ , which is obtained by bubbling  $\text{CO}_2$  into a soln. of alkali silicate, washing and drying the ppt. and dehydrating it at 200–500°.

**Catalyzers.** DEUTSCHE GASGLÜHLICHT-AUER-G. M. B. H. Ger. 473,824, Dec. 30, 1925. See Brit. 263,758 (C. A. 22, 144).

**Hydrogenation catalysts.** GEORGES HUGEL, MARCEL PAUL, and MAURICE BOISHEL. Fr. 649,976, Feb. 27, 1928. Hydrides of Na, K, Rb, Cs, Ca, Sr, Li or Ba are used as hydrogenation catalysts in the treatment of *hydrocarbons* or *coal-distn. products*. They may be stabilized by impregnating them with org. solvents such as tetralin, or by using them in combination with CO, or mixed with metallic amides.

**Removing catalyst poisons and other impurities from gases such as nitrogen-hydrogen mixtures.** I. G. FARBENIND. A.-G. Brit. 298,726, Aug. 10, 1927. The gases are treated with reactive metals such as the alkali or alk. earth metals, Pb, Cd, Sn or Bi dissolved or finely distributed in melts of salts, oxides, hydroxides or other metals. An example is given of the treatment of a N-H mixt. with Na and a small quantity of Fe in a NaOH melt.

**Condensation products.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 130,420, July 25, 1927. A mol. of benzoin and a mol.  $\beta$ -naphthalenesulfonic acid are allowed to react in the presence of a condensing agent. The product can be used as a distributing agent for insol. substances.

**Phenol condensation products.** J. KARPATI and M. G. HUBSCH. Brit. 298,968, Oct. 18, 1927. Products resembling natural asphalt mineral wax or resins are formed by reaction of phenols or phenolic compds. and finely divided cellulosic material, *e. g.*, by reaction at a temp. of about 110–120° between air-dried sawdust and crude brown-coal-tar creosote in the presence of a small proportion of  $\text{H}_2\text{SO}_4$ . The reaction may require 2–3 hrs. and the properties of the product may be modified by subsequent heat treatment or by admixt. with a previously obtained condensation product, tar oil or other substances. By suitably varying the proportions of the reacting substances and using HCl as a reaction accelerator, products of high m. p. are obtained which may be used in road making, roofing or in the manuf. of insulating material, lacquers, etc.

**Viscous phenol condensation product.** RICHARD GÜNTZEL (to the Firm Schieferwerke Ausdauer A.-G.). U. S. 1,711,411, April 30. A mixt. comprising phenol, *p*-dichlorobenzene and  $\text{CH}_2\text{O}$  is heated in the presence of a mixed salt comprising NaCl,  $\text{NH}_4\text{Cl}$  and  $(\text{CH}_2)_6\text{N}_4$ , water is sepd., volatile vapors are driven off, and the product may then be washed with water, and if desired may be hardened.

**Phenolic condensation product.** OSCAR A. CHERRY and FRANZ KURATH (to Economy Fuse Mfg. Co.). U. S. 1,710,722, April 30. A phenolic compd. is heated with  $\text{CH}_2\text{O}$  in the presence of furfuralamide, while the phenolic compd. is maintained in excess of the combining proportion with the  $\text{CH}_2\text{O}$ , to form a product which is suitable for use in making molded articles. Cf. C. A. 22, 3056.

**Phenol-aldehyde condensation products.** BRITISH DYESTUFFS CORP., LTD. and E. E. WALKER. Brit. 298,680, July 15, 1927. In forming condensation products by condensing a phenol first with an aliphatic ketone such as acetone and then with an aliphatic aldehyde (the second or both reactions being effected in an alk. medium), the alkali is neutralized with acid after the second condensation until the aq. layer after agitation with the oily layer has a  $\text{pH}$  of between 5 and 7, and the oily product is then sepd. and crystd. and may be used in various mixts. for making molded products. Various details and examples are given.

**Formaldehyde-albumin derivs.** HERMANN REIL. Ger. 472,820, Feb. 7, 1926. Powd.  $\text{CH}_2\text{O}$ -albumin derivs. are prepd. from animal blood or its constituents by treating carefully with the correct quantity of  $\text{CH}_2\text{O}$  completely to sat. the amino acid groups of the albumin. The product flakes and is allowed to stand for several days at 42°, when it is dried and powd.

**Moldable composition.** SIDNEY M. HULL (to Western Electric Co.). U. S. 1,711,025, April 30. Condensation of a substantially dry protein material such as casein and substantially anhyd. furfural is effected in the presence of a waterproofing material such as a rosin-glycerol ester to form a product suitable for molding. Cf. C. A. 22, 484.

**Moldable composition containing nitrocellulose and a phenol-aldehyde condensation product.** STABILIMENTI CHIMICI INDUSTRIALI. Brit. 298,793, Nov. 15, 1927. Cellulosic material is treated with  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$ , washed, dried, soaked in phenol and then treated with  $\text{CH}_2\text{O}$  and may be further treated with a neutralizing agent such as  $\text{Na}_2\text{CO}_3$ , drained, dried and mixed with *p*-dichlorobenzene. The product may be roughly shaped at  $60^\circ$  and molded under pressure at  $160^\circ$ .

**Molding casein compositions.** A. ZSIGMONDY. Brit. 298,815, Dec. 22, 1927. Buttons or other molded articles are formed by punching or cutting out rough blanks from a casein compn. in unhardened condition, hardening the blanks and shaping and finishing under a very high pressure (suitably 400–500 atm.) at a temp. of  $90\text{--}100^\circ$ . An app. is described.

**Plastic compositions.** BUTO-WERKE G. M. B. H. Ger. 474,851, Aug. 3, 1926. Plastic masses are prepd. from horn, ivory and neats-foot chippings by softening the outer layer with alkali, removing it mechanically and treating to the usual pressing operations.

**Plastic compositions.** ELECTRICAL RESEARCH PRODUCTS, INC. Ger. 474,624, Dec. 3, 1924. Addn. to Ger. 457,698. Plastic masses are prepd. from rubber, guttapercha, balata and similar substances by mixing with filling material, such as  $\text{H}_2\text{SiO}_3$ , which has been previously heated, without sublimation, to a temp. below the sintering temp., *e. g.*,  $900\text{--}1000^\circ$ .

**Coloring horn.** H. OEXMANN. Brit. 298,946, Oct. 17, 1927. Coloring of horn with dyes is rendered more permanent by treating the horn with  $\text{CH}_2\text{O}$  or adding the latter to the dye compn. used for the coloring.

**Cement.** HUGO VIERHELLER. Ger. 473,702, Mar. 22, 1928. Fusible cement made from phosphates is purified by subjecting it in a finely ground condition to an oxidizing glowing process.

**Cements.** SOC. D'ÉTUDES CHIM. POUR L'IND. Swiss 130,107, Oct. 13, 1927. Liquid cements are purified by oxidizing the impurities by gaseous or solid oxidizing agents.

**Shaft kiln with annular combustion chamber for lime, cement, etc.** AXEL HERMANSEN. Ger. 474,067, Jan. 21, 1926.

**Outlet lock for shaft kilns for lime, cement, etc.** ALBIN B. HELBIG. Ger. 474,022, Aug. 20, 1927.

**Furnace for producing phosphoric acid, etc.** STETTINER CHAMOTTE-FAB. A.-G. VORM. DIDIER. Ger. 473,410, Sept. 22, 1925. See Brit. 289,128 (*C. A.* 23, 678).

**Peat composition.** BOHUMIL JIROTKA. Ger. 474,821, Aug. 14, 1921. Material for making objects by pressing is made from moist, ground peat. Filling or binding material,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ ,  $\text{NaOH}$ , sawdust or dyes may be admixed.

**Gramophone disks.** THE GRAMOPHONE CO., LTD. Fr. 649,964, Feb. 27, 1928. A conducting layer is obtained on wax or the like in making gramophone disks, by creating a vacuum over the wax, introducing a gas such as  $\text{H}_2\text{S}$  and then dipping the wax in a soln. of a salt such as  $\text{SnCl}_2$  or  $\text{AgNO}_3$  to obtain a film of sulfide of Ag or Sn.

**Gramophone disks.** THE GRAMOPHONE CO., LTD. Fr. 649,820, Feb. 25, 1928. In the production of gramophone records the matrix of wax or soap-like material is brushed with finely divided Cu or Cu and graphite and a mirror of Ag is deposited on the bronzed surface by a reduction process.

**Gramophone records.** H. LAFFON. Brit. 298,434, Feb. 16, 1928. Foundation layers and coatings of records are each formed of compns. contg. a cellulose ester and a plasticizing agent and may contain condensation products and fillers, which if desired may be applied as coatings on paper. Various details are given.

**Adhesives and sizes.** I. F. LAUCKS, INC. Brit. 298,511, March 28, 1927. Vegetable protein material such as soy-bean flour is treated with a S-contg. agent in which the S is bonded to C but not to O, such as *n*-propyl disulfide, methyl disulfide, allyl sulfide, benzyl sulfide and disulfide,  $\text{CS}_2$  or thiocarbonates. Alk. base compds. such as  $\text{NaOH}$  or  $\text{Ca(OH)}_2$  may be added, as may also "retarders" such as alkali metal or alk. earth metal chlorides such as  $\text{NaCl}$  or  $\text{CaCl}_2$ . Protein material from cottonseed, linseed or peanuts also may be used. Various compns. are described in some of which rosin and other auxiliary ingredients are used.

**Gelatin threads, tubes, ribbons, etc.** P. HIRSCH. Brit. 299,105, July 25, 1927. Violin strings or other products made from gelatin solns. are treated with germ-killing rays, preferably ultra-violet rays, or the soln. from which the products are formed are similarly treated.

**Chewing gum.** HENRY M. MOWREY (to United Chicle Co.). U. S. 1,711,281, April 30. A tacky binder such as a rubber or chicle compn. is mixed with powd. sugar

at such a temp. that the sugar remains in its solid form, and powd. yeast is added at intervals in equal quantities of approx. 20% of the entire quantity.

**Mineral wool.** ISOLA-G. M. B. H. Ger. 473,821, April 30, 1926. Mineral wool is manufd. by a device in which a stream of molten mineral flows into a current of compressed air from a nozzle with a trough-shaped orifice.

**Emulsion.** HANS SCHENK. Swiss 130,100, June 21, 1928. A soln. of *p*-dichlorobenzene in  $C_6H_6$ , water and an emulsifying agent are mixed.

**Purification of gases.** I. G. FARBENIND. A.-G. Fr. 649,444, Jan. 31, 1928. Gases or vapors such as CO,  $H_2S$ ,  $AsH_3$ , steam, etc., are removed from gases to be used in catalytic reactions by passing the gases over alkali or alk. earth metals or very reactive compds. free from O, on finely divided or porous substances. Thus, a mixt. of H and N for the production of  $NH_3$  is washed with liquid  $NH_3$  and passed over one of the substances referred to. Spongy Fe dipped into a soln. of NaCN and heated to 550–600° in a stream of H may be used.

**Stencil sheets.** A. DE WABLE. Brit. 298,705, July 22, 1927. Yoshino paper or similar material is coated with a compn. comprising gelatinizing org. colloids such as nitrocellulose which do not dissolve in water, converted into weak gels or viscous sols by use of org. liquids (such as AmOAc and castor oil with nitrocellulose) and then formed into emulsions with aq. media such as gelatin or agar. Sulfonated sperm oil may be used as an emulsifying agent and bentonite may be added. Cf. C. A. 22, 2645.

**Transparent sheets.** SOC. ANON. POUR L'IND. CHIM. A. BALE. Fr. 649,602, Feb. 23, 1928. Transparent sheets for motor car screens, etc., are formed by uniting sheets consisting of condensation products of urea and  $CH_2O$  or their derivs. The compd. sheet may consist of a central sheet of softer compn. with outer sheets of harder compn.

**Finely divided substances.** BRITISH DYE STUFFS CORP., LTD. Fr. 649,551, Feb. 22, 1928. Finely divided substances are treated in suitable app. in mixt. with an amt. of dispersion agents and dispersion fluid such that at the end of the operation it forms a viscous paste which solidifies in a permanent manner. Thus, 25 parts of sulfite cellulose pitch are worked in a mixer with 100 parts of a paste of indigo and water. Other examples are given.

**Dispersion agents.** BRITISH DYE STUFFS CORP., LTD. Fr. 648,728, Sept. 28, 1927. Derivs. of ligninsulfonic acid (sulfite cellulose pitch) are obtained by treating it at a raised temp. with an  $NH_3$  soln. or with a hydroxide or carbonate of an alkali metal with or without pressure and final acidification. The products are dispersion agents particularly for vat dyes or in dyeing acetate silk.

**Disperse systems.** J. R. GEIGY A.-G. Ger. 474,284, Apr. 20, 1926. See U. S. 1,696,374 (C. A. 23, 921).

**Porous fillers.** ANDRÉ SOLIGNAC. Fr. 649,755, July 21, 1927. Cork charcoal obtained by heating pieces of cork to a temp. not above 600° is used as filling material for vessels contg. dissolved  $C_2H_2$ , etc.

**Artificial fog.** HANSEATISCHE APPARATEBAU-GES. VORM. L. VON. BREMEN & CO. Brit. 298,980, Oct. 18, 1927. In atomizing under pressure a fog-forming acid material such as  $SO_2$  dissolved in chlorosulfonic acid, the pressure is produced at the time of use by the generation of gases by the dehydrating reaction of the fog-forming acid on org. substances such as formic or oxalic acid.

**Photomechanical reproduction.** ART. INSTITUT ORELL FÜSSLI. Ger. 473,856, Oct. 11, 1927. Prints are transferred from low-pressure plates to stone or metal by coating the object with coloring material and a transparent layer, and etching with  $FeCl_3$  or citric acid. The transparent layer may be celluloid or collodion soln.

**Printing plates.** NEW CENTURY PRESS, LTD. Australia 11,115, Jan. 5, 1928. An ordinary cast plate is allowed to cool, dipped in a weak soln. of KCN and then in a bath of Ni. The plate is washed in KOH soln. and Cu is deposited by electrolysis on the printing face.

**Printing plates and foils.** I. G. FARBENIND. A.-G. (Hugo Dibelka, inventor). Ger. 472,750, July 14, 1927. See Brit. 293,834 (C. A. 23, 1730).

**Coating materials with metal foil.** ALUMINIUM-WALZWERKE SINGEN, DR. LAUBER, NEHER Co. GES. Brit. 298,593, Oct. 12, 1927. Foil such as that of Al is secured to paper, textiles, celluloid, glass, metal, leather, masonry, wood or other materials by an adhesive which is insol. in water and does not fuse or soften when heated to temps. used in working the material coated with the foil and that sets by an "irreversible" setting process. Among the adhesives that may be used are: cellulose ester varnishes, solns. of resins or rubber, metal soaps, ordinary varnishes and artificial resin varnishes. Various examples and modifications are described.

**Metal-foil substitute.** CHEM. FABRIK VON HEYDEN A.-G. Ger. 473,919, April 3,

1924. A metal-foil substitute is formed by a layer of cellulose ester soln. and bronze powder. The solvent is allowed to evap. at a temp. at least  $25^{\circ}$  below its b. p.

**Metallic paper.** HERBERT GLOOTZ. Ger. 472,714, July 19, 1927. Addn. to Ger. 401,514. Metallic powder is sprinkled on paper coated with adhesive. The sheet is then wound on a roller and the metallic surface produced by pressing or heating the powder to cause it to cohere.

**Coating compositions.** GEORGE KING and RICHARD THRELFALL. Fr. 649,782, Feb. 14, 1928. See Brit. 290,717 (C. A. 23, 942).

**Removing grease from metal objects.** ALEXANDER WACKER, GES. FÜR ELEKTROCHEM. IND. G. M. B. H. Ger. 474,825, Dec. 19, 1926. Grease is removed from metal objects before subjecting them to further manufg. processes, in a device comprising two superposed chambers, the lower one contg. a non-inflammable solvent of low b. p., such as  $C_2HCl_3$  or  $CCl_4$ . The lower chamber is kept at the b. p. of the solvent and the upper one is kept cooled.

**"Antifreezing" composition for cooling systems of engines, etc.** ARTHUR H. OSTERLUND. U. S. 1,711,324, April 30. Glycerol is used with Na glycerophosphate, which serves to form a mixt. permanently miscible with water.

**Chiolite.** I. G. FARBENIND. A.-G. (Fritz Sander and Erich Kayser, inventors). Ger. 473,511, May 25, 1924. Addn. to Ger. 473,408. Chiolite is prepd. by heating cryolite, obtained as in the way described in the prior patent, with aq. mineral acid solns. with or without addn. of Al salt soln.

**Utilizing fish fins.** WALTER THORMÄHLEN. Ger. 474,065, Mar. 20, 1927. The fins are rendered suitable for hat trimming and other decorative purposes by cutting them to suitable shapes, washing in lukewarm soda soln., steeping for some hrs. in a soln. of 1 kg. alum and 0.5 kg. NaCl in 30 l. water, drying, steeping for 30 mins. in a soln. of an aniline dye and drying again. They may then be tipped with Au or Ag or otherwise decorated, e. g., by electroplating.

**Carbon tetrachloride.** FÉLIX NEUVILLE and LUCIEN MAUGÉ. Fr. 649,934, Aug. 4, 1927. Decompn. of  $CCl_4$  in fire extinguishers is retarded by adding dehydrating substances such as  $ZnCl_2$  or  $CaCl_2$ , which may be coated with paraffin or stearin.

**Foam for fire-extinguishing.** R. SCHNABEL and EXCELSIOR FEUERLÖSCHGERÄTE A.-G. Brit. 299,097, July 22, 1927. A foam-generating liquid such as a saponin soln. is supersatd. under pressure with a gas such as  $CO_2$  in a closed container and the container is sealed until the material is desired for use.

**High-pressure gas cartridge suitable for fire-extinguishing purposes.** G. SCHWORETZKY and EXCELSIOR FEUERLÖSCHGERÄTE A.-G. Brit. 299,096, July 22, 1927. Structural features.

## 19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

Some interesting physicochemical phenomena exhibited by minor constituents in glass. W. E. S. TURNER. *J. Soc. Chem. Ind.* 48, 65-7T (1929).—If the glass batch is wet before being melted the glass is stiffer and sets more quickly. It is likely that the moisture retained to a late stage of the melting process or even permanently does not exceed 0.05% of the glass. Arsenic is either wholly or mainly retained in both Na Ca silicate and K Pb silicate glasses. When 250 parts  $As_2O_3$  per 1000 sand was used, the amount retained at  $1350^{\circ}$  was 78% and at  $1400^{\circ}$  was 53% of the total added, although the amounts varied somewhat as the result of difference of charging conditions. Instead of a tendency to reduction at  $1350$ – $1400^{\circ}$  the  $As_2O_3$  tends to form  $As_2O_5$  and from 40 to 70% of the total may be present as  $As_2O_5$ . This change occurs in the absence of oxidizing agents. The stability of  $As_2O_3$  soln. in glass at high temps. is remarkable. The transmission of short wave lengths of light by a glass is closely connected with the iron oxide content and with the relative proportions of  $FeO$  and  $Fe_2O_3$ . For satisfactory transmission the  $Fe_2O_3$  should not exceed 0.03%. For any iron oxide content the transmission of the  $FeO$  glass is wider. A diagram gives a comparison of the effects of  $Fe_2O_3$  and  $FeO$  on the limit of transmission in the ultra-violet of a glass of approx. compn.  $SiO_2$  75,  $CaO$  10,  $Na_2O$  15 melted in platinum. Glasses contg. 92–94% of iron as  $FeO$  undergo no change in transmission with irradiation. By heating at about  $600$ – $700^{\circ}$  in a gas flame, irradiated glass with impaired transmission can be rejuvenated.

D. E. SHARP

The value of different types of glass for transmitting ultra-violet light. EDWIN T. WYMAN, ARTHUR D. HOLMES, LAWRENCE W. SMITH, DONALD C. STOCKBARGER AND MADELINE G. PIGOTT. *Am. J. Diseases Children* 37, 473-82(1929).—Corning glass is practically transparent to the ultra-violet radiations which are effective in the treatment of rickets. Vitaglass is comparatively less transparent, and ordinary window glass, opaque. E. R. MAIN

Influence of boric oxide on the dispersion of optical glasses in the near infra-red. T. DREISCH AND P. LUED. *Z. Physik* 49, 380-5(1928).—The  $n$  to 6 significant figures has been detd. for a no. of optical glasses, with and without a  $B_2O_3$  content, in the range  $0.5-2.5 \mu$ ; the difference between the index for  $1.47$  and  $2.39 \mu$  is approx. proportional to the boric acid content. B. C. A.

Absorption of ultra-violet glasses. C. WINTHER. *Z. wiss. Phot.* 25, 230-2(1928).—Curves given show the ultra-violet transmission for a no. of specimens of ultra-violet glass and of ordinary plate glass. Variation of thickness of the glass specimens was adjusted by altering the exposure time according to the method of Henri. B. C. A.

Signal green and the absorption of copper oxide in glasses of various compositions. E. ZSCHIMMER. *Sprechsaal* 62, 169(1929).—The permeability factors for signal green specified previously (cf. C. A. 21, 2768) should have the following values. Blue, wave length  $444 \mu\mu$ , lower limit 0.29; green, wave length  $528 \mu\mu$ , lower limit 0.30; red, wave length  $656 \mu\mu$ , upper limit 0.025. C. H. LORIG

Composition and hydrolytic stability of household pressed glass. C. A. BECKER AND CH. KRAFT. *Sprechsaal* 62, 261-2(1929).—Chem. analyses were made of 11 household pressed glasses and their hydrolytic properties were detd. by the standard grit method and by a rapid method. The comps. of these glasses fall within the range of 74.5-76.0%  $SiO_2$ , 4.5-8.5%  $CaO$  and 14.0-20.0% alkalies. A favorable compn. for this glass should contain at least 5%  $CaO$  and as a max. 19% alkalies. The soly. of the glass as detd. by the standard grit method amounts to 0.03-0.08 g.; in the rapid method 1.8-7.2 cc. 0.01  $N$   $HCl$  was required for 50 cc. of soln. C. H. LORIG

The compressive and transverse strength of brick. J. W. MCBURNEY. *Bur. Standards J. Research* 2, 821-35(1929).—See C. A. 23, 2543. E. H.

The petrography of some magnesite bricks. C. W. CARSTENS AND KR. KRISTOFERSEN. *Norsk Geol. Tids.* 10, 1-13(1928).—The article records results of chem. analysis of magnesite bricks from 3 different localities, one being Austria. Compression tests at different temps. up to  $1730^\circ$  are discussed. Expts. on some of the minerals used in making magnesite bricks gave the following results: On heating to its m. p. ( $1500^\circ$ ) serpentine ( $H_4Mg_3Si_2O_{10}$ ) gives  $Mg_2SiO_4 + MgSiO_3 + H_2O$ . Talc ( $H_2Mg_3Si_4O_{12}$ ) heated to  $1500-1550^\circ$  gives  $3MgSiO_3 + SiO_2 + H_2O$ . Enstatite ( $MgSiO_3$ ) heated with  $MgO$  gives  $Mg_2SiO_4$ . O. A. NELSON

The mathematical basis of burning brick. II. W. SCHUEN. *Tonind.-Ztg.* 53, 532-4(1929); cf. C. A. 23, 2260.—The formula for the rate of heat flow into the ware is:  $Q = \lambda F(T_1 - T_2)/\delta$ .  $Q$  is the quantity of heat in kg.-cal. transferred in 1 hr. from the surface to the middle of the body.  $\lambda$  is a const. depending on the property of the substance; for clay burned at  $900^\circ$  it is 1.115.  $F$  is the surface in sq. m.  $T_1 - T_2$  is the temp. difference between the surface and the center of the body.  $\delta$  is the distance the heat must travel. Curves show the speed of ignition of acetylene, ethylene, methane, H and CO at various dilns. A table shows the cal. per l. of mixts. of the same gases with O at  $0^\circ$ ,  $1400^\circ$  and  $1800^\circ$ . R. F. FERGUSON

Economies in crucible manufacture. E. PROBST. *Sprechsaal* 62, 243-4(1929). C. H. LORIG

Standardization of wall tile and stoneware tile. ANON. *Tonind.-Ztg.* 53, 503-5(1929).—Glazed wall tile are tested for water absorption and resistance to acids as follows: After drying at  $100^\circ$ , to const. wt., the pieces are placed in water to  $1/4$  their depth for 1 hr. and to  $1/2$  their depth for another hr. At the end of the 2nd hr., they are immersed to  $3/4$  their depth for 22 hrs. and then fully covered for 24 hrs. The wt. of absorbed water is expressed in % of the dry wt. Resistance to acids is detd. by exposing the glazed surface for 24 hrs. to concd.  $HCl$  at room temp. Mosaic tile are tested for bulk sp. gr., water absorption, frost resistance, resistance to abrasion and resistance to acids. Bulk sp. gr. is detd. by weighing suspended in water, or by measuring. Water absorption is obtained as described. Resistance to freezing is detd. by cooling the satd. piece to  $15^\circ$  for 2 hrs. Resistance to abrasion is detd. by exposing the samples to a sand blast operating at a pressure of 3 kg./sq. cm. Resistance to acids is detd. by soaking for 7 and 14 days in 10%  $HCl$  and 10%  $NaOH$ . R. F. FERGUSON

Kaolins of Ukraina. V. I. LUCHITZKII. *Trans. Inst. Econ. Mineral. Met.* (Moscow) 1928, No. 41, 3-244.—Ukrainia possesses 43,151,000 tons residual kaolin deposits

and 5,897,300 tons sedimentary kaolin deposits; only 25,312,000 tons of the former and 2,143,700 tons of the latter have an industrial value. The m. p. of the purified Ukrainian sedimentary kaolin is close to normal, namely, 1830°. The quantity of feldspar admixed is not excessive; quartz is present in quantities less than 1-2%; mica is rare; the % of SiO<sub>2</sub> and Al<sub>2</sub>O<sub>3</sub> is close to normal; Fe oxides are, in the majority of cases, not above 1%; CaO is mostly less than 0.5%; MgO usually fluctuates between a trace and 0.3%; TiO<sub>2</sub> usually fluctuates between 0.36 and 1.5%; Mn oxides and org. substances occur only in exceptional cases and in very small quantity. This compn. compares favorably with that of the best foreign kaolins. The process of kaolinization of the Ukrainian cryst. formation took place in 2 stages: (1) In Pre-Cambrian times the kaolinization was started by the pneumatolytic process not very far under the surface of the earth; (2) in the Pre-Devonian period the kaolinization was completed by the process of erosion.

BERNARD NELSON

**The formation of magnesium ferrite in sintered magnesite.** W. WEYL. *Tonind.-Ztg.* 53, 559-62(1929).—A compd. of the formula MgO.Fe<sub>2</sub>O<sub>3</sub> was prepd. by sintering equal mol. quantities of MgO and Fe<sub>2</sub>O<sub>3</sub> to 1200° and then heating with 3 times its wt of KCl in a Pt crucible at 1200° for 40 hrs. By this method, crystals were obtained of sufficient size to be positively identified as spinel. By comparing the x-ray spectrum of this compd. with that of calcined magnesite, the conclusion was reached that, at least in the case of low-silica magnesites, the iron after calcining is in the form of magnesium ferrite, a compd. of the spinel type.

R. F. FERGUSON

**Coated abrasive products, 1928.** Simplified Practice Recommendation R89-28, Elimination of Waste Series. U. S. Bur. of Standards. 20 pp.

E. J. C.

**The corrosion of refractory material.** W. NEIMANN. *Tonind.-Ztg.* 53, 484 (1929).—The usual method is to place slag in a hollow test piece or a brick into which a hole has been drilled. The m. p. of the slag used should be detd. and a temp. used in the test sufficiently higher to insure fluidity. Slag with too high a m. p. is not advisable, as the brick might vitrify in the test. Usually a slag melting at 1350° is employed. In refractories for special purposes, such as crucibles and glass-house material, it is best to use temp. and fluxing agents similar to those encountered in service.

ROBERT F. FERGUSON

**The enameling of cast iron.** A. MÜLLER. *Giesserei-Ztg.* 26, 158-60(1929).—Cast iron that is to be enameled should analyze: Si 2.3-2.6, Mn 0.6-0.9, P 0.6-0.9, S 0.08-0.1, C 3.6-3.7%. Of these, C has the greatest influence on enameling. The influence of C, P, Si, S and Mn is discussed briefly.

J. W. W. SULLIVAN

**Refractories in the gas industry (SMITH, SPIERS) 21.** The clays of East Prussia and their properties (KRAUSE) 8. The chemistry and biology of the clay pits (SEBENTZOV, ADOVA) 8. Annealing and hardening furnace (Swiss pat. 130,010) 1.

ANSELL, H. AND SEARLE, A. B.: **The Making and Burning of Glazed Ware.** London: H. Greville Montgomery. 268 pp. 12s. 6d.

**Glass.** GLASSFABRIK A.-G. (Gerhard Stein, inventor). Ger. 473,458, June 26, 1925. Molds or molding tools for use with glass in a thermoplastic state are prepd. from a relatively soft material, e. g., soft Fe, and are then coated on the working surface with Cr. Molds with sharply defined patterns can be so obtained.

**Electric glass-melting furnace.** AKTIESELSKAPET RÆDERS ELEKTROGLASOVEN. Ger. 472,780, Sept. 19, 1925. Details of construction.

**Furnace tanks for molten glass and associated apparatus.** LEONARD D. SOUBIER (to Owens Bottle Co.). U. S. 1,710,789-90, April 30. Structural features.

**Furnace with cooling canals for table glass.** PILKINGTON BROS., LTD. Ger. 472,781, Nov. 13, 1924. Details of arrangement.

**Apparatus for forming glass tubes and rods.** R. SALOMON. Brit. 298,561, Oct. 11, 1927.

**Device for rolling glass sheets into cylinders.** NAAMLÖÖZE VENNOOTSCHAP MIJ. TOT BEHEER EN EXPLOIT VAN OCTROOIEN. Ger. 474,754, Mar. 16, 1927.

**Device for conveying glass plates to the annealing furnace.** NAAMLÖÖZE VENNOOTSCHAP MIJ. TOT BEHEER EN EXPLOIT VAN OCTROOIEN. Ger. 474,755, May 31, 1927.

**Plate glass.** COMPAGNIES RÉUNIES DES GLACES ET VERRES SPECIAUX DU NORD DE LA FRANCE. Brit. 299,034, Oct. 21, 1927. The entire contents of glass in a melting pot are poured into the receiver of a rolling app. and heated in the receiver, and the

glass strip formed in the rolling app. is thence passed to an annealing lecr provided with conveying rollers.

Glass transparent to ultra-violet rays. H. P. HOOD (to Corning Glass Works). Brit. 298,908, Oct. 15, 1927. Details are given for the production of glasses such as described in Brit. 263,410 (C. A. 22, 148), batch materials which are free from Fe and Ti being used. Details of purifying the batch materials are specified. Glasses which transmit ultra-violet rays lose their transmitting power gradually on continued exposure to ultra-violet rays or sunlight but by heating (suitably to about the annealing temp.) their transmitting power may be restored.

Composite sheets of glass and cellulose nitrate or cellulose acetate. J. J. ROWE. Brit. 298,888, June 22, 1927. A clear cellulose deriv. varnish which may contain cellulose nitrate or acetate is applied to the glass and allowed to dry and the glass is then united by heat and pressure to a sheet of celluloid or like material.

Porcelain and glass. DEUTSCHE GOLD- UND SILBER-SCHNEIDANSTALT VORM. ROESSLER. Fr. 649,666, Feb. 24, 1928. Combinations of porcelain and glass are made by fusing together glass, the coeff. of expansion of which does not pass about  $5.10^{-4}$  and the softening point of which is the same as that of the porcelain glazing, and a porcelain, the coeff. of expansion of which is as high as possible. Silicate or borate glasses such as those called "Pyrox" and "Supremax" are particularly suitable.

Inspection glass for ceramic and like kilns. JEAN HEINSTEIN. Ger. 474,414, Oct. 16, 1927.

Continuous tunnel kiln for burning ceramic wares. TAINÉ G. McDOUGAL (to A. C. Spark Plug Co.). U. S. 1,710,995, April 30. Structural features.

Ceramic furnaces. EDWARD G. SPENCER-CHURCHILL. Fr. 649,971, Feb. 27, 1928. Ceramic furnaces are arranged in a group around a common chimney and have means for passing the hot gases from one furnace to the next so that they may be used in a cycle.

Ceramics. HARRY ZIMMER. Ger. 472,743, April 24, 1927. Porcelain objects are made by pouring layers of varying granular texture into the mold.

Ceramics. "SFINX" SPOJENÉ SMALTOVNÝ A TOVÁRNÝ NA KOVOVÉ ZBOŽÍ, AKCIOVÁ SPOLEČNOST. Ger. 472,583, Oct. 2, 1926. Decorative effects are produced on ceramic and metal-coated ware by applying glazing material contg. water or salt soln. in the form of drops, in the rough glazing process, and then firing in the usual way.

Molds for pottery. WILLIAM J. MILLER. Fr. 648,899, Dec. 30, 1927.

Abrasives. SOC. ANON. DES MANUF. DES GLACES ET PRODUITS CHIM. DE ST.-GOBAIN, CHAUNY ET CIRÉY. Fr. 648,402, June 23, 1927. See Brit. 292,611 (C. A. 23, 1486).

Artificial sharpening stones. C. BORODAY. Belg. 354,120, Oct. 31, 1928. Two plastic masses are prepd. consisting, resp., of (1) abrasive powder, talc, S, glycerol, dye,  $MgCl_2$  and calcined  $MgO$ ; and (2) corundum, S, glycerol, dye,  $MgCl_2$  and calcined  $MgO$ . A layer of one of the compns. is placed in a mold, and a layer of the 2nd placed over the 1st so as to obtain a 2-face stone.

Refractory materials. SOC. ANON. DES MANUF. DES GLACES ET PRODUITS CHIM. DE ST.-GOBAIN, CHAUNY ET CIRÉY. Fr. 649,736, July 19, 1927. See Brit. 294,179 (C. A. 23, 2007).

Refractory masses. G. POLYSIUS EISENGIESSEREI. Ger. 470,422, Oct. 9, 1925. Addn. to 464,312. Ger. 464,312 describes the manuf. of refractory masses, intended particularly as furnace linings, by calcining a mixt. of a fusible cement with suitable addns. such as corundum. Such products are now improved by providing a dense surface on the fire side and a porous surface on the side away from the fire. This is done by using coarse granules of corundum for the side away from the fire and finer granules for the fire side. Cf. C. A. 22, 2449.

Porous refractory bricks. IVAR SETTERBERG. Ger. 474,021, July 1, 1927. See Brit. 281,254 (C. A. 22, 3505).

Refractory bodies. HERMANN SALMANG and FLORENZ GOETH. Ger. 474,415, May 28, 1927. Refractory bodies of improved properties are prepd. by heating the initial materials to softening temp. under strong pressure, *e. g.*, a refractory clay is heated in a C mold to  $1450^\circ$  under a pressure of 4 kg. per sq. cm.

Casting refractory materials. G. S. FULCHER (to Corning Glass Works). Brit. 298,983, Oct. 18, 1927. See U. S. 1,700,288 (C. A. 23, 1487).

## 20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

**Electric investigation of the setting and hardening of rapid-hardening cements.** YOSOMATSU SHIMIZU. *Science Repts. Tôhoku Imp. Univ.* 1st. ser. 17, No. 7, 1218-25 (1928).—See C. A. 23, 1237. E. C. M.

**The production of slag cements.** CLERET DE LANGAVANT. *Ciment* 34, 150-7 (1929).—General. F. O. A.

**Action of sulfur in slag cements.** JEAN CLERET DE LANGAVANT. *Rev. matériaux construction trav. publics* 1929, 41-4.—The action of S in the slag on the Fe compds. in the cement to form FeS, which is later oxidized to FeSO<sub>4</sub>, is probably without serious harmful effect. F. O. A.

**The manufacture of supercement.** N. C. KYRIACOU. *Rev. matériaux construction trav. publics* 1928, 417-20, 451-6; 1929, 16-20; cf. C. A. 22, 3276; 23, 496.—Machinery is described. A cement made in Chalkis, Greece, has the compn.: SiO<sub>2</sub> 20, Al<sub>2</sub>O<sub>3</sub> 3, Fe<sub>2</sub>O<sub>3</sub> 8, CaO 65%; it gives very high early strengths. F. O. ANDEREGG

**Resistance to deterioration.** MAURICE NOYER. *Rev. matériaux construction trav. publics* 1928, 461-4; 1929, 21-3.—A description of the action of phys., chem. and atm. agents upon the materials used in masonry and in reinforced concrete and their control by means of tests in the lab. and on the job. F. O. A.

**Waterproofing concrete extracts of marine algae.** G. BELAY. *Ciment* 34, 177-82 (1929).—It is claimed that concrete is made more impermeable and durable if a suitable amt. of ext. of marine algae is added to the gaging water. The hydration and workability are said to be improved. F. O. A.

**The determination of the specific gravity of trass.** A. STROPOR. *Inst. Ind. Chem. Bucharest. Tonind.-Zig.* 53, 618-20 (1929).—The sp. gr. of trass depends upon whether it has been heated and upon the liquid used. The sp. gr. of dried trass increases as kerosene is added to C<sub>2</sub>H<sub>5</sub>, while with raw trass the change is in the other direction. Standard specifications are needed. F. O. A.

**Commercial manufacture of Carborundum, Elektrokorund and Elektroschmelzement.** SCHNEIDLER. *Metallbörse* 18, 708 (1928).—Elektrokorund is cryst. Al<sub>2</sub>O<sub>3</sub>; Elektroschmelzement consists mainly of CaO and Al, instead of silicates like portland cement. E. M. SYMMES

**A new apparatus for burning gypsum.** L. MARTIN. *Tonind.-Zig.* 53, 655-6 (1929).—In the app. developed by Hermann Völker of Munich, the raw gypsum comes in contact with a coil filled with oil heated to the proper temp. F. O. A.

**History of plaster of Paris.** TATE. *Ciment* 34, 158-62 (1929). F. O. A.

**The production of dry hydraulic, hydrated lime.** WALTER MARSCHNER. *Tonind.-Zig.* 53, 669-70 (1929). F. O. A.

**Testing method for roofing felt.** P. W. CODWINE. *Paper Mill* 52, No. 8, 46, 48, 154, 156; *Paper Trade J.* 88, No. 9, 43-5 (1929).—A survey and discussion of the methods for the following detns., as applied to roofing felts: wt., thickness, strength test, tensile breaking strength, bursting strength, tearing strength, ash, fiber compn., satg. characteristics, kerosene test, oil penetration test and xylene test. A. P.-C.

**The Kyan method of impregnating coniferous wood.** WILLY KINBERG. *Tek. Tid., Uppl. C, Kemi* 58, 94-6 (1928).—K. has patented an improvement of the Kyan method. The new feature is a preliminary treatment of the wood with vapors of chem. solvents. While still hot, the wood is treated with the soln. of HgCl<sub>2</sub> at a temp. of 80°. The soln. of HgCl<sub>2</sub> penetrates the wood to a depth of 30-40 mm.; by the original Kyan method the depth of penetration does not usually exceed 5 mm. C. A. R.

**The fiber saturation point of wood as obtained from electric conductivity measurements.** ALFRED J. STAMM. *Ind. Eng. Chem., Anal. Ed.* 1, 94-7 (1929).—The elec. resistance of wood changes very rapidly with changes of its moisture content up to a certain value (cf. C. A. 22, 858); a linear relationship exists in this space between the log of the elec. cond. and the moisture content. This linear relationship is the same in all species studied (8 softwoods and 1 hardwood). In the region above the limiting value where the elec. cond. increases in a parabolic way with the increase of the moisture content, the values for different species are different. The point of tangency of the parabolic curve with the straight line may be considered as the fiber satn. point, that is, the limit of the water absorption by the fiber walls. This point differs slightly among the species studied, varying from 28.5 to 31.5% of H<sub>2</sub>O, in good agreement with results obtained by measurements of other phys. properties of the wood.

Resoaking does not influence the fiber satn. point, whereas extn. raises it in redwood.

**Laboratory methods of testing the toxicity of wood preservatives.** HENRY SCHMITZ. *Ind. Eng. Chem., Anal. Ed.* 1, 76-9(1929).—Methods of testing the toxicity of wood preservatives are reviewed. Both the impregnated-wood methods and the nutrient-agar methods show specific disadvantages. To prevent losses of preservatives due to the volatilization during the sterilization process, it is proposed to seal the preservative in a weighed glass bulb and to place it in the Erlenmeyer flask before the latter is sterilized. By breaking it afterward with a glass rod the desired preservative-agar mixt. can be prepd. J. WIERTELAK

**The structure of soft woods as revealed by dynamic physical methods.** ALFRED J. STAMM. *Colloid Symposium Monograph* 6, 83-108(1928).—Studies of electroendosmotic flow were used to det. the total effective capillary cross section of several soft woods. App. is described and the formulas used are given. From the rate-change of flow with changing thickness of transverse section, the max., min., and av. tracheid lengths were detd., as well as the effective continuous pit-communication cross section. By combining the data on electroendosmotic flow with those obtained from studies of hydrostatic flow, detns. were made of av. effective diam. for pit-membrane pores and lumens. The latter agree well with microscopic measurement, while the former are of the same order of magnitude as the pores in other natural and artificial membranes. Max. tracheid values from both methods agree well. The repellent effect of surface tension to permeability was overcome by pressure, from which the same two diams. were detd. Lumen values check with the microscope, but pit-membrane values for pore diams. were 4-8 times greater than those from other methods. Max. tracheid length values calcd. from surface tension data agree with those from other methods. Western red and Alaska cedars, Sitka spruce, Western yellow pine and Douglas fir (Rocky Mt. type) were all partially permeable to colloidal mercury and to India ink sols, but also acted as partial ultrafilters. JEROME ALEXANDER

**CHILDE, H. L.: Manufacture and Uses of Concrete Products and Cast Stone.** London: Concrete Publications, Ltd. 5s. net. Reviewed in *Engineering* 125, 361, *Rock Products* 31, 87(1928).

**Ornamental coatings on wood (U. S. pat. 1,711,330) 26.** Kiln for drying lumber (U. S. pat. 1,711,100) 1. Treating petroleum residues (with production of paving) (Austrian pat. 112,441) 22. Shaft kiln with annular combustion chamber for lime, cement, etc. (Ger. pat. 474,067) 18. Outlet lock for shaft kilns for lime, cement, etc. (Ger. pat. 474,022) 18.

**Portland cement.** I. G. FARBENIND. A.-G. Brit. 298,943, Oct. 17, 1927. Ca sulfide 5% or less is added during grinding of the cement, to improve its hydraulic properties.

**Fused cements.** SOC. D'ÉTUDES CHIMIQUES L'INDUSTRIE. Brit. 298,637, Oct. 13, 1927. Reducing impurities in fused cements prepd. from bauxite or from slags produced in the manuf. of P or  $H_3PO_4$  from mineral phosphates are removed by treating the melted mass with oxidizing agents, such as O,  $CO_2$ ,  $MnO_2$ , or Fe oxide.

**Forming hollow articles such as columns or pipe from cement compositions.** JOHN A. CARR. U. S. 1,710,919, April 30. A plastic compn. such as a cement mixt. is deposited in a vertical mold and the mold and contents are subjected to a repeated, partial and reciprocated rotation, which serves to produce a dense uniform product. An app. is described.

**Lightweight concrete.** ROY CROSS and WM. A. COLLINGS (to Silica Products Co.). U. S. 1,710,921, April 30. A product, which in the air-dried condition weighs 85-130 lbs. per cu. ft., is formed from a bath comprising hydraulic material such as portland cement together with cinder screenings and kieselguhr or other suitable mineral filler and a gelatinizing clay such as bentonite adapted to expand when brought into contact with moisture and to hold the aggregate in suspension in the aq. vehicle.

**Road treatment with sulfite cellulose lyes.** SOC. ANON. DES USINES DIOR. Fr. 650,107, Aug. 9, 1927. These lyes, concd. or not, or mixed with bitumen, tar, pitch, etc., are used for waterproofing roads.

**Bituminous composition for roads, etc.** F. MORTON. Brit. 298,812, Dec. 20, 1927. Pitch (suitably having a "twisting point" between 40° and 65°) is mixed with a pure bitumen (suitably 5-25% the quantity of the pitch) and with mineral aggregate

(forming 80–90% of the final mixt.) such as broken granite or slag and stone dust or sand. Cf. C. A. 23, 2568.

**Bitumen emulsions.** VICTOR WINTSCH, JR. Fr. 648,917, Feb. 4, 1928. Latex is used in making emulsions of bitumen or asphalt for roads, etc.

**Paving materials.** CYRIL E. RAMSDEN. Ger. 473,250, Aug. 13, 1925. A paving and surfacing material suitable for tennis courts comprises granular silicious material, e. g., flint, colored green by treatment with Cr compds. followed by firing. Binding mediums, e. g., rubber, latex, fatty oils and oxidized fatty oils, may be used in laying the material.

**Rubber-faced paving blocks.** M. HOLMES. Brit. 298,457, June 18, 1928. Structural features are described of blocks, which may be formed of metal coated with asphalt or the like to which the rubber facing is in turn attached.

**Building stone.** ARTHUR TETZNER. Ger. 473,822, June 25, 1927. Building stone is made from loam, sand and cement, the loam and sand being intimately mixed as a gravelly mass by milling and pulverizing.

**Artificial stone.** ROBERT SCHERER. Austrian 112,627, Nov. 15, 1928. Layers of paper or the like coated with a Sorel cement, e. g., a mixt. of MgO with MgCl<sub>2</sub>, are superposed, pressed and dried.

**Artificial marble.** LOUIS TOCCO. Fr. 649,931, Aug. 3, 1927. Objects are molded in Ca(OH)<sub>2</sub> alone or mixed with sand, etc., and coloring or other substances and heated in an oven contg. CO<sub>2</sub> under pressure to about 200°.

**Cinder block for building construction.** EMIL LUZZATTI and HARRY M. SCHLOSS. U. S. 1,711,027, April 30. A "ground material" comprising cinders of about 0.06–0.25 in. in size 75% and finely ground shell or lime 25% is used with about 1/3 its quantity of cement and with sufficient water to form a properly bonding mixt.

**Building sheets.** SIDNEY J. HIPPER. Australia 16,936, Nov. 21, 1928. Building sheets or slabs, which may be sawed and nailed like timber, are composed of plaster of Paris, coke breeze, cement, flax or fiber and water.

**Porous plaster composition.** C. GAMARRA. Brit. 298,607, Oct. 12, 1927. Calcined gypsum contg. carbonate is mixed with reagents which react with each other or with the carbonate assocd. with the gypsum to liberate CO<sub>2</sub> and to form insol. compds. such as CaCl<sub>2</sub> and tartaric acid.

**Roofing felt, paper or floor covering material.** C. A. E. LEECH and D. LEECH. Brit. 298,862, March 29, 1928. Fibrous reinforcing material such as cotton, hessian, or string is embedded in the material while in the soft pulpy state.

**Floor covering compositions.** D. L. IRWIN and R. E. TIPPINS. Brit. 299,178, Oct. 13, 1927. A felted fibrous material is coated with a compn. contg. a solid filler such as red slate flour and Fe oxide together with pitch, rosin and a dispersion of casein, which may comprise borax and ammonia; over this a top coating of a linoleum compn. may be applied.

**Composite tiles of wood and rubber.** H. P. STEVENS. Brit. 298,522, July 8, 1927. A layer of plywood is united by vulcanization with a powerful accelerator at a low temp. with a rubber compn. such as may be formed from rubber 75, tire reclaim 50, S 4, ZnO 20, clay 50, "mineral rubber" 10 and Zn diethyldithiocarbamate 0.5 part.

**Impregnation of woods.** E. DAL. Belg. 354,606, Oct. 31, 1928. The preserving agent is creosote to which is added one or more powerful toxic compds., particularly Pb resinates. A typical formula is: Pb(OAc)<sub>2</sub> 2.5, resin oil 2, bitumen 5, anthracene 5, tar 5, heavy benzene 20, heavy creosote oil 40.5, cresylic acid 20.

**Treating wood.** UNTERNEHMUNG FÜR HOLZIMPRÄGNIRUNG G. LOEWENFELD. Austrian 112,636, Nov. 15, 1928. The impregnation of wood is facilitated by first subjecting it while damp to a temp. sufficiently low to freeze the contained water, and thereafter drying it at an elevated temp.

## 21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

**Gasification of fuel with pure oxygen.** J. GWOSDZ. *Feuerungstech.* 16, 241–6 (1928).—A critical review of various proposals, calcns. and pieces of exptl. work.

ERNEST W. THIELE

**The treatment of coal.** C. H. LANDER. *Gas J.* 185, 344–5, 412–3, 608–9 (1929).—A series of lectures covering microscopic examn. of coal, the use of powdered fuel, the decompn. point of coal, high-temp. and low-temp. carbonization, the development of the

continuous vertical retort, heating of retorts, clean raw material and hydrogenation.

**F. S. G.**  
**Manufacture of anthracene in U. S. S. R.** P. I. SOKOLOV. *J. Chem. Ind. (Moscow)* 6, 22-4 (1929).—The coal region of Donetz has colossal potential anthracene resources. The Kuznetsk coal region in Siberia possesses potential anthracene resources which are not inferior to the Donetz region. Anthracene manufactured in the Kuznetsk region analyzes: anthracene 43-8%, carbazole 34-6%, moisture 5-11%, ash 0.3-0.5%, phenanthrene 12-14%; it contains no methylanthracene and gives anthraquinone and alizarin of good quality. Donetz anthracene differs from it by contg. more phenanthrene and less carbazole; it is not suitable for the manuf. of anthraquinone by oxidation with chromic mixt.

**BERNARD NELSON**  
 Remarks on the present status of the manufacture of coal products. *F. MÜLLER. Erdöl u. Teer* 5, 102-4, 118-9, 136-7 (1929).—A review. **F. S. GRANGER**

**Correlation between the adsorption capacity of coals and peats and their other characteristics.** B. P. PENTEGOV. Vladivostok Univ. *Publ. Far Eastern State Univ. Vladivostok* [7], No. 12, 3-28 (1929).—The extent of maturity of coal, *i. e.*, the degree of fossilization, or metamorphosis, is characterized by its colloidal state; the more it is advanced, the greater the decrease of unsatd. non-oriented C atoms, as well as the decrease of the colloidal phase, whereas the oriented C atoms, and consequently the cryst. phase, is enhanced. As adsorption is a property of colloids, the younger the coals the more hygroscopic moisture they contain. On this principle is based a *method of coal classification* according to the extent of their adsorptive capacity. The other existing methods of coal classification only permit crudely to distinguish typical coals from typical brown coals; they are not reliable and give indefinite results with coals of intermediate groups. Hence Stadnikov and Proskurnina (*C. A.* 20, 3342) proposed to distinguish coals according to the nos. of mg. of  $\text{Fe}_2\text{O}_3$  they can adsorb from 75 cc. of 0.1% aq.  $\text{FeCl}_3$  solns. P. altered this method by taking equal weights (1 g.) of coals, brown coals, peats, etc., at a definite state of pulverization (70-mesh sieve) and detg. their adsorptive capacity by contact with 50 cc. of 0.1% solns. of  $\text{FeCl}_3$ , methylene blue, and oxalic acid. In various Siberian coals the adsorption nos. change inversely with the degree of maturity of the coals taken. The influence of the extent of air exposure to which the coals were subjected must be taken in consideration, since weathering off considerably decreases the adsorption capacity. The oxalic acid adsorption no. is less affected than that of the 2 other reagents by the action of air on coal. The adsorptive nos. of the cokes are just as characteristic as those of the respective coals from which they were obtained. The ratio of the adsorptive no.  $A_1$  of the coal to that,  $A_2$ , of its coke, is usually less than 1 for coal, almost equal to 1 for anthracite, less than 1 for peat, and more than 1 (sometimes more than 2) for brown coals. Weathering off lowers the value  $A_1/A_2$ , as the effect of exposure is to lower the adsorption power of a coal much more than that of its coke. From the effect of the exposure on the ratio  $A_1/A_2$  it is easy to see that the latter is also connected with the occurrence of coals. In fact,  $A_1/A_2$  increases with the depth of the coal stratum. The gas content of coals is also a function of their adsorptive capacity. *Spontaneous combustion* of coals, which is sometimes blamed on their pyrite contents, in reality results from their great adsorption capacity: after adsorbing sulfates from aq. solns., and after reducing the sulfates into sulfides, they are naturally apt to become self-inflammable. As the *coking process* consists in the decompn. of coal with formation of the solid, liquid, and gaseous phases, and as this decompn. is followed by the adsorption and decompn. of the liquid and the gaseous phases by the solid phase, it is evident that the greater or less adsorptive capacity of the solid phase affects the character of the coke obtained. The *hydrogenation of various coals* by F. Fischer's method by means of  $\text{HCO}_2\text{Na}$  in presence of  $\text{H}_2\text{O}$  at  $400^\circ$  also depends on the adsorption no. of the coals; the greater the latter, the better the yield of ether-sol. hydrogenation products. **BERNARD NELSON**

The determination of the degree of decomposition of peat. (The determination of cellulose.) VASSILI I. KOMAREVSKII. *Z. angew. Chem.* 42, 336-8 (1929).—Air-dried samples of peat were ground in a hand mill and sieved; the ash and water contents were then detd. Ten-g. samples were extd. in a Soxhlet with  $\text{Et}_2\text{O}$  (27 hrs.),  $\text{EtOH}-\text{C}_6\text{H}_6$  (1:2) (24 hrs.), and with  $\text{Et}_2\text{O}$  (2 hrs.) to remove wax, resin and their bituminous decompn. products. Adhering solvent was removed in a vacuum desiccator. Treatment with 200 cc. of 1% soln.  $\text{NaOH}$  (12 hrs.), in a centrifuge flask, was followed by 20 mins' centrifuging at 2000 r. p. m.; the operation was repeated twice, and then alkali removed by washing with  $\text{H}_2\text{O}$ . Alternate treatment with  $\text{ClO}_2$  (1.5 and 10% soln.) and  $\text{Na}_2\text{SO}_3$  (2% soln.) was made to remove humic substances and lignin, leaving crude cellulose of about 4% ash content. The residue was washed with  $\text{H}_2\text{O}$ ,  $\text{EtOH}$  and  $\text{Et}_2\text{O}$ .

parisons with Cross and Bevan's method indicate that their results are higher for crude cellulose, and that when their cellulose is purified as above their results fall slightly below those found by the present author.

**Carbonization in vertical retorts.** Some working experiences. W. C. EBAUGH Neath Corp. Gas Wks., Wales. *Gas J.* 186, 32-4 (1929).—Advantages of downward heating, uniformity of blending, cleaning of fires, dust removal, life of retorts, scurrying, control of calorific value and fuel consumption, with reference to Woodall-Duckham retorts, are discussed.

**By-product coke plant at Hamilton.** C. I. HALDEMAN. *Blast Furnace & Steel Plant* 17, 688-90 (1929).

The new central coking plant at the Emil Mine, Essen-Altenessen. R. GAU. *Z. Vcr. deut. Ing.* 73, 437-40 (1929).—Old coking plants with 260 furnaces and 520,000 tons (coke) per yr. capacity have been replaced by 3 batteries of 39 furnaces each, having an output of 800,000 tons per yr.; provision is made for a fourth battery of 39 furnaces also. Each chamber has a capacity of 17.8 tons moist coal (12%  $H_2O$ ), is 12 m. long, 3.6 m. high and has a width (center) of 0.475 m. Time of heating is usually 20-21 hrs., but is sometimes reduced to 18-19 hrs. From the 117 furnaces about 1650 tons of coke, 75 tons of tar, 26 tons  $NH_3$  sulfide, and 16 tons  $C_6H_6$  are obtained daily. The dry coal mixt. used yields about 75.5% of dry coke. The construction and operation of the plant are outlined. Through complete mechanization the output per man is about 8 times as great as it was at the older plants, the heat economies are much greater, and the recovery of by-products through the Feld process is much better. W. C. E.

**Recovery of phenol from the wash water of coking plants.** PAUL HOENING. *Z. angew. Chem.* 42, 325-31 (1929).—Compelled to remove  $C_6H_5OH$  from wash water because it created a nuisance in the rivers into which it was drained, coking plants in the Ruhr district will soon be adding 5000-6000 tons of this material per year to the 11,000 tons now brought upon the (German) market. Pyridine will also be recovered in quantity. The wash water contains only 2-3 g./l., and the discharge into the rivers must not run more than 0.6-0.8 g./l. The Pott-Hilgenstock process is used, *vis.*, extn. of the wash waters with an immiscible solvent like  $C_6H_6$  or its homologs, sepn. of the aq. and  $C_6H_5OH$ -contg. layers by gravity, and recovery of the  $C_6H_5OH$  by distn. of this soln. or by treatment with alkali. Diagrammatic plans of the pilot plants used for this purpose, together with descriptions of processes and data of exptl. runs are presented. Treatment with alkali proves to be preferable to distn., both because of the cost of recovery and the quality of the material made. It is calcd. that 100 kg. of  $C_6H_5OH$  recovered by distn. cost 28.07 M., and by the alkali process 17.67 M. In the Ruhr district alone more than 30,000 tons of  $C_6H_5OH$  is available annually.

**Complete gasification.** Humphreys & Glasgow combination plant. ANON. *Gas J.* 185, 727-9 (1929).—The plant layout and working results and the economic advantages of complete gasification are outlined.

**Dehydration of gas efficiently accomplished at low cost.** G. A. BRAGG, Koppers Co. *Chem. Met. Eng.* 35, 731-3 (1928).—Cost ests. are presented for reducing the humidity of coal and water gas by (1) scrubbing with cold  $CaCl_2$  soln., (2) refrigerated water, and (3) compression above distributing pressure. Costs range from 5.8 to 10.4 mills per M.

**The future type of gas supply.** J. BUIJS. *Het Gas* 49, 215-9 (1929).—A discussion of the economical advantages of vertical inclined and horizontal chamber ovens for gas plants. A detailed table is given of the cost of production including by-products, coke, wages, etc., of 1000 cu. m. gas in 6 large gas plants, 2 of each type, in Holland. For coal the price is fl. 10 (guilders) per ton (gas coal) for vertical or inclined ovens; it is fl. 9 per ton for horizontal ovens (coking coal); the coal cost per 1000 cu. m. gas is fl. 20.94-26.96 fl., with a by-product yield of 19.50 to 28.82; the av. net gas price per 1000 cu. m. amounts to fl. 1.24 for vertical ovens (intermittent), fl. 2.51 for inclined ovens and fl. 0.91 for horizontal ovens. The coke price assumed of fl. 13.50 per ton for all 3 types of ovens would be considerably better (fl. 19) for horizontal ovens if special attention is paid to its production. All figures indicate the superiority of the horizontal oven type for plants of daily production more than 50,000 cu. m.; the central gas supply from coke-oven plants at the mines will in many cases be the most economical soln.

B. J. C. VAN DER HORVEN

**Manufacture and condensation of carbureted water gas.** TERENCE H. MADDEN. *Gas J.* 185, 748-9; *Gas World* 90, 290-2(1929).—The Humphreys and Glasgow plant and practice, at the Grangetown Wks. of the Cardiff Co., are discussed generally, with special reference to tar removal, describing particularly the Cascade tar-fog separator described in *C. A.* 22, 2455.

**Making carbureted water gas.** M. BARIL. *Gas World* 90, 251(1929).—It was found experimentally that cracking of gas oil starts at about 500°. The thermal efficiency passes through a max. at about 650°. The vol. of cracked gas increases continuously from 550° to 900°, while its heating value decreases. Benzene increases up to 900°, while toluene and xylene diminish. Naphthalene is at a max. at 750°. On the whole, the most effective temp. range is 650 to 700°. Differences in results in cracking oil alone and in presence of blue gas, as in practice, are attributed to certain light hydrocarbons escaping condensation, in consequence of diln. No reaction between water gas and the products of cracking was observed. Thermal efficiency is improved by bubbling the blue gas through the gas-oil tars.

**Generator for double-gas.** E. LANGTHALER. *Feuerungstech.* 16, 246-8(1928).—L. describes a water-gas generator for coal in which the gases pass around a retort in the generator and carbonize the fuel.

**Hydraulic mains. Theory and practice.** S. L. WRIGHT. Colne, Eng. *Gas J.* 186, 151-2(1929).—A general discussion.

**Observations on American gas engineering practice.** S. G. WATSON. W. C. Holmes & Co., Ltd., London. *Gas J.* 185, 860-2; 186, 29-32, 93-6(1929).—A general survey covering factors influencing methods of gas manuf. cooling and condensation, exhausters, ammonia recovery, removal of H<sub>2</sub>S, water, naphthalene, etc., and metering.

**Low-temperature tars.** MAILHE. *J. usines gaz* 53, 103-10(1929).—Tars of good quality were obtained by distg. specimens of lignite and bituminous coal with a little superheated steam at temps. below 460°. The phenols from lignite, distg. below 240°, on treatment with SnCl<sub>2</sub>, lost most of their S, were decolorized and acquired a pure phenolic odor. This reagent, however, had little effect on the neutral oil. By treatment of the bituminous coal tar with MeOH, EtOH or iso-PrOH, dild. to densities between 0.85 and 0.86, neutral oil was obtained almost free of phenols, but the phenols contained proportions of neutral oil ranging from 2% for MeOH, to 20% for iso-PrOH. The latter, however, extd. the phenols most completely from the neutral oil. The neutral oil was cracked in the liquid state with AlCl<sub>3</sub>, FeCl<sub>3</sub>, ZnCl<sub>2</sub> and SnCl<sub>2</sub> and in the vapor state with Cu or Ni. In the former case, H and, in the latter, olefins and paraffins predominated in the gases obtained, and the percentage of lower-boiling liquids increased considerably. The phenols, b. above 250°, distd. with ZnCl<sub>2</sub>, yielded 35% of liquid products, contg. considerable proportions of hydrocarbons b. 100-350°, cresols and xylenols, gas, in which H predominated, and a residue of C.

KLEIN, G.: *Handbuch für den deutschen Braunkohlenbergbau.* Teil 1. Berlin: VDI-Buchhandlung. 511 pp. Bound, M. 43.

NAPHTALI, MAX: *Die Kohle und ihre Wandlungen.* Berlin: Ullstein. 136 pp.

**Fuel.** DURNFORD & ELLIOTT (SHEFFIELD), LTD. Ger. 474,592, Aug. 18, 1923. App. for obtaining oil, gas and smokeless fuel from coal, shale, peat or wood comprises a barrel-shaped distg. chamber rotating about a radial axis. Openings are provided in the bearings for loading, and side outlets with valves for the escape of the volatile products of the distn.

**Fuel.** JULES J. DESCHAMPS. Ger. 472,812, May 25, 1923. The combustion of solid and liquid fuels is facilitated by introducing them into the firing chamber as small particles suspended in an air charge.

**Fuel. GES. FÜR MASCHINELLE DRUCKENTWÄSSERUNG M. B. H.** Ger. 474,558, Mar. 16, 1927. Peat is dried by grinding it to particles of the order of 0.3–0.2 mm. and mixing with peat powder which has been dried to hardness.

**Fuel. GES. FÜR MASCHINELLE DRUCKENTWÄSSERUNG M. B. H.** Ger. 474,860, Feb. 17, 1927. Mechanically pressed, dried and powd. peat is coked and mixed with peat powder.

**Fuel. I. G. FARBENIND. A.-G.** (Martin Müller-Cunradi, inventor). Ger. 472,855, Feb. 5, 1924. A fuel for lighting, heating and smelting comprises butylene or butane or a mixt. of these with each other or with other readily liquefied substances of which they form the principal part.

**Fuel. SOC. DE RECHERCHES ET DE PERFECTIONNEMENTS INDUSTRIELS.** Ger. 474,499, Oct. 12, 1926. A fuel resembling anthracite is prepd. by compressing and degasifying the compn. obtained by adding non-caking coal, especially anthracite, to the coal-oil mixt. obtained in the Trent process of purifying coal. (Cf. U. S. 1,420,164, (C. A. 16, 1928).)

**Gasifying bituminous fuels. ALBERT BREISIG.** Austrian 112,342, Oct. 15, 1928. Addn. to 107,421. The method of Austrian 107,421 (C. A. 22, 4778) is modified by extending the blasting period so as to increase the flow of heat to the accumulators. A large removable excess of coke is so obtained, and the CO content of the gases is reduced. Cf. C. A. 23, 1249.

**Filter for separating powdered fuel from air, etc. J. J. C. BRAND and B. LAING.** Brit. 299,080, July 19, 1927.

**Treating powdered fuel for internal-combustion engines. I. G. FARBENIND. A.-G.** (Josef Jannek and Gerhard Hofmann, inventors). Ger. 474,181, May 8, 1926. Brown-coal dust or like powd. fuel for Diesel or other internal-combustion engines is pretreated with HF, preferably in the dild. gaseous state, to remove SiO<sub>2</sub>.

**Distilling powdered fuel. TROCKNUNGS-, VERSCHWELUNGS-, UND VERGASUNGS G. M. B. H.** Fr. 649,479, Feb. 6, 1928. See Brit. 285,015 (C. A. 22, 4777).

**Destructive distillation. ALLGEMEINE VERGASUNGS-GES. M. B. H.** Ger. 474,357, Feb. 11, 1926. Fine coal or the like descends a shaft and is heated by hot inert gases both directly and indirectly. The shaft is traversed by hollow bars through which the heating gases pass, each alternate bar having openings in the bottom.

**Destructive distillation. FIRMA CARL STILL.** Ger. 474,356, Nov. 6, 1925. In distg. solid fuels in horizontal, externally heated ovens, the yield of by-products, particularly hydrocarbons, is improved by withdrawing all the distn. products through the surfaces of doors at the ends of the oven, the doors lying below the surface of the fuel.

**Destructive distillation of bituminous materials. KOHLENVEREDLUNG A.-G.** Ger. 474,339, Mar. 18, 1924. The finely granular or powd. materials are carried by a gas stream through a series of heating zones. Gas and solid may be sepd. on leaving each zone.

**Destructive distillation of coal. KURT BEUTHNER.** Ger. 473,844, Feb. 7, 1928. The lower closing door of the distg. app. can pivot about a frame after it is opened.

**Distillation retorts. ARTHUR V. ABBOTT.** Ger. 473,212, July 25, 1926. The distillation products from a rotary coal-distn. retort are cooled by a conical cooler arranged near the outlet of the retort.

**Oven for the low-temperature distillation of coal or lignite. H. HARDY.** Belg. 353,911, Oct. 31, 1928. Constructional features.

**Liquefaction of coal. MICHAEL MELAMID.** Fr. 649,474, Feb. 3, 1928. Coal is finely powd., mixed with a powd. catalyst or dissocn. agent and injected by means of H or a protection gas contg. H into the reaction vessels under pressure.

**Apparatus for separating materials such as pulverized coal and slate by flotation. WALTER L. REMICK.** U. S. 1,711,326, April 30. Structural features.

**Synthesis of hydrocarbons. ALFRED UHLMANN.** Fr. 650,029, Jan. 5, 1928. Hydrocarbons are obtained by passing a mixt. of substances contg. C and H, such as charcoal, graphite or coke and water made into a paste, through a high-frequency field. O and CO<sub>2</sub> formed are combined by adding metallic powders and CaO or MgO to the materials. H may be passed through the material being treated and the hydrocarbons obtained may be treated with a catalyst such as Ni. A suitable app. is described.

**Destructive hydrogenation. I. G. FARBENIND. A.-G.** Brit. 299,020, Aug. 7, 1926. Catalysts are used contg. the metalloids B, Si, P, As, Se or Te in free or combined state, preferably in conjunction with elements of the 2nd to 8th groups of the periodic system (particularly those of the 6th group); e. g., there may be used Si carbide, alderwood charcoal glowed at 800° and treated with H<sub>3</sub>PO<sub>4</sub> or Ca phosphate, Mo

phosphate, W phosphate or Fe phosphate;  $As_2O_3$  alone or preferably with Mo or W; silicides such as Fe silicide contg. 15% Si; active silica hydrosilicates; borides such as those of Ti or Fe; or molybdic acid contg. Na selenite. Brit. 299,021 specifies catalysts contg. halogens in either free or combined state, preferably in combination with elements of the 2nd to 8th groups and most suitably the 6th group of the periodic system, *e. g.*,  $CaF_2$ , Mo together with 10%  $AlCl_3$  or  $CdCl_2$ .

**Destructive hydrogenation of carbonaceous materials.** I. G. FARBERIND. A.-G. Brit. 298,584, June 9, 1927. Products of destructive hydrogenation of carbonaceous materials are polymerized (suitably after a preliminary treatment to increase their content of unsatd. compds.) to form hydrocarbons of high mol. wt. and especially to produce rubber-like substances. The preliminary treatment may include cracking, dehydrogenation, thermal or elec. treatment. Halogens may be introduced into the hydrocarbon mol. and halogen acids subsequently split off. A product of the destructive hydrogenation of oil is treated with  $SO_2$ ; the solid products which settle are heated or treated with alkalis and substances thus obtained can be polymerized with metallic Na into rubber-like substances. A coal hydrogenation product, dehydrogenized by passing over Cr oxide at  $500^\circ$  may be treated with HCl and distd. to yield  $AmCl$ , which may be treated with  $BaCl_2$  at  $400^\circ$  to form trimethylethylene, which is further treated with Cl, *in vacuo*, to form chloroamylene, and HCl is split off with production of isoprene, which is then polymerized with  $SnCl_4$ . A coal hydrogenation product may be cracked at redness in the presence of quartz or Pt to form butadiene, which may be polymerized with Na. Cf. C. A. 23, 2276.

**Reduction furnaces.** PAUL L. J. MIGUET. Fr. 648,813, June 25, 1927. The smoke products and dust from reduction furnaces are incorporated with coal-dust to be used for making coke for the reduction process.

**Recovery of motor fuel from crude oil, coal, etc.** ERNEST SCHULTZ and ERNEST L. SCHULTZ. Australian 9,692, Oct. 4, 1927. A high percentage of light oil is recovered from org. materials such as crude oil, shale, coal, etc., by vaporizing the raw material in a still, passing the vapors to a converter contg.  $CaO$  and  $ZnCl_2$  or  $ZnO$ , which are agitated by paddles and cause the gases to react under pressure that gradually increases; so that after the gases have been condensed an odorless high-grade oil is produced.

**Eliminating corrosive properties of benzene.** THEODORE R. TRAINOR (one-half to Joseph A. Kelly). U. S. 1,711,367, April 30. A lime soln. is added to the benzene and the mixt. formed is forcibly circulated in a closed system, a  $NaHCO_3$  soln. is added and the mixt. is further circulated. An app. is described.

**Montan wax.** I. G. FARBERIND. A.-G. Brit. 299,133, Aug. 20, 1927. Montan wax is purified by treatment with an elec. current in an aq. medium, *e. g.*, a soln. contg.  $H_2SO_4$  and Cr sulfate, or compds. of Mn, V or Ce, with or without org. acids and org. solvents. Various details of the treatment are described.

**Drying gases.** W. C. HOLMES & Co., LTD. Fr. 648,739, Nov. 21, 1927. Coal gas is dried at about atm. temp. by contact with liquid absorbents and then by contact with cooled absorbents preferably liquid, the absorbents being regenerated either continuously or periodically. Cf. C. A. 23, 2513.

**Purification of gases.** SOC. INTERNATIONALE DES PROCÉDÉS PRUDHOMME-HOUDRY. Fr. 650,101, Aug. 8, 1927. In the manuf. of liquid fuels the hot distn. gases are purified by metals or oxides, *e. g.*, an oxide of Ni, in 2 series of purifiers alternately placed out of circuit for regeneration and by a pair of check purifiers following the main app. and put in and out of circuit at much longer intervals and contg. metals such as Cu oxides which form sulfides stable at the operative temp. of about  $250^\circ$ .

**Combustible gases.** I. G. FARBERIND. A.-G. Fr. 649,301, Dec. 3, 1927. Combustible gases are produced from moist granular fuel, such as crude friable lignite, by drying the latter in the lower part of the furnace or outside this, preferably by means of the warm gases themselves and mixing the charge of fuel by an agitator, which may be cooled.

**Generator gas.** C. OTTO & Co. G. M. B. H. Ger. 474,569, May 26, 1928. Generator gas is cooled and purified by passing it through an oppositely flowing stream of such substance as sand, or ceramic or metallic powder.

**Water gas and hydrogen.** IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 649,780, Feb. 9, 1928. See Can. 281,814 (C. A. 22, 4235).

**Purifying furnace gases.** DAN RADULESCU. Fr. 648,773, Jan. 7, 1928. App. for purifying furnace gases comprises a conduit in which a no. of radial agitators rotate at high speed, dividing the conduit into chambers. Supersatd. steam and water or other liquid are injected through nozzles.

**Recovery of ammonia from gases.** ALLGEMEINE VERGASUNGS G. M. B. H. Ger. 473,986, July 9, 1926.  $\text{NH}_3$ -contg. gases formed in the burning of N-contg. fuels are extd. by adding to the blast of air, vapor at such a high temp. that the final temp. of the mixt. is at least  $200^\circ$ ; the  $\text{NH}_3$  content is absorbed directly from the waste gases.

**Gas producer.** FRANZ ENDRES. Ger. 473,486, Mar. 6, 1927. A vertical retort for the manuf. of coal gas is adapted for the simultaneous manuf. of oil gas by arranging an oil gasification chamber between the heat regenerators and the outlet pipe for the coal gas.

**Gas producer suitable for motor vehicles.** M. DELVAUX. Belg. 354,149, Oct. 31, 1928. Device for removing dust from gas, particularly producer gas. Belg. 354,150, Washer for producer gas for motor vehicles. Belg. 354,151. Constructional.

**Inverted gas producers.** PAUL HEUMEZ and EDMOND HUBERT. Fr. 649,927, Aug. 3, 1927. Means are provided for preventing tars and other liquids from entering the gas stream.

**Suction gas producer with annular boiler.** MOTORENFABRIK DEUTZ A.-G. Ger. 473,405, Dec. 23, 1924.

**Water-jacketed gas-producer construction.** MOTORENFABRIK DEUTZ A.-G. Brit. 298,649, Oct. 13, 1927.

**Cooler for viscous liquids.** GABRIEL SZIGETH and JOSEF BECKKÓY. Ger. 473,793, May 1, 1926. A cooling app. for such liquids as coal tar has a vertical cooling element with upstanding plates with horizontal troughs in which the tar flows.

**Purifying oils and tars from coal distillation, etc.** F. HOFMANN and C. WULFF. Brit. 298,484, Oct. 6, 1927. Coal distn. products are refined by treatment with a soln. of HCl in an org. solvent such as benzine,  $\text{C}_6\text{H}_6$ , "light oil," MeOH, EtOH or  $\text{CCl}_4$ ; the process may be applied to low-temp. tar, tar oils, oils obtained by the destructive hydrogenation of coal, etc., benzene and lubricating oils obtained as described in Brit. 299,086 (cf. C. A. 22, 3079). After the HCl treatment the oil is washed with water and caustic alkali soln. and then distd.

**Purifying oils containing tar acid.** SOLOMON CAPLAN (to Combustion Utilities Corp.). U. S. 1,710,764, April 30. In order to remove color-producing impurities from oils such as tar or shale oils, the oils are extd. with a soln. of a "buffer" agent such as a 1% aq.  $\text{NH}_3$  soln. and the ext. is sepd. from the residual oil. Cf. C. A. 22, 2457.

**Tar distillation.** THE BARRETT Co. Fr. 649,528, Feb. 17, 1928. The gases from tar distn. by contact with part of the hot gases from a coal distn. battery are mixed with the remaining gases which have been cooled to remove heavy tar constituents, and the mixt. obtained is cooled to recover condensable constituents.

**Tar distillation.** THE BARRETT Co. Fr. 649,533, Feb. 18, 1928. See Brit. 286,278 (C. A. 23, 266).

**Apparatus for the distillation of tar.** THE BARRETT Co. Fr. 648,796, Feb. 2, 1928.

**Decolorizing waste water from crude tar-extracting plant.** FRITZ SEDENSCHNUR. Ger. 472,519, May 27, 1925. Addn. to Ger. 401,467. The water is decolorized by the  $\text{H}_2\text{SiO}_3$ - and Fe-contg. clinker from generators or furnaces.

**Sulfonated tar.** ORIN D. CUNNINGHAM (to Peter C. Reilly). U. S. 1,711,448, April 30. In treating coal tar for the production of a material suitable as a base to be employed as a filler or pigment or for decolorizing material the tar is mixed with more than its own wt. of cold strong  $\text{H}_2\text{SO}_4$  and the mixt. is heated (suitably at a temp. of about  $100$ – $70^\circ$ ) to effect sulfonation. Claim is made to a completely sulfonated tar as a new product.

**Sulfonated pitch.** ORIN D. CUNNINGHAM (to Peter C. Reilly). U. S. 1,711,449, April 30. Coal-tar pitch in the solid state is mixed with strong  $\text{H}_2\text{SO}_4$  and agitated, and the mixt. is heated to about  $160$ – $70^\circ$  and then cooled and run into water, the mass removed from the water and free acid removed (suitably by washing with water). A sulfonated pitch is obtained which has decolorizing properties and is suitable for use in treating solns. of glucose or other substances.

**Coking.** KOHLENSCHIEDUNGS-G. M. B. H. Ger. 473,709, June 11, 1921. A rotary drum app. for the destructive distn. of coal, peat and lignite, has a tube entering well into the drum to lead away the tar-oil vapors.

**Dry cooling of coke.** KOHLENSCHIEDUNGS-G. M. B. H. Ger. 472,803, Oct. 7, 1923. The glowing coke is mixed with cooling material which absorbs the heat and is then sepd. from the coke.

**Calcing coke.** ALUMINUM Co. OF AMERICA. Ger. 474,359, Jan. 15, 1927. See U. S. 1,671,673 (C. A. 22, 2657) and Brit. 269,849 (C. A. 22, 1286).

**Coke oven.** EVENCE COPPÉE & Cie. Ger. 472,679, Mar. 17, 1928. Addn. to Ger. 455,419. Details of construction.

**Coke oven.** C. OTTO & Co. G. M. B. H. Ger. 473,782, April 4, 1926. Details of arrangement.

**Coke-oven construction.** H. KOPPERS A.-G. (to Koppers Coke Oven Co., Ltd.) Brit. 298,945, Oct. 17, 1927. Coke ovens with passages in their foundations have the ferroconcrete flooring divided into slabs with expansion joints between them and these slabs are supported by iron shoes on pillars and struts from which they may be sepd. by heat-insulating material.

**Regenerative coke oven with vertical heat blast.** GUTEHOFFNUNGSHÜTTE OBERHAUSEN A.-G. Ger. 473,959, Oct. 21, 1925.

**Plant for using the maximum heat from refined coke.** COLLIN & Co. and JOSEF SCHÄFER. Ger. 472,510, May 13, 1925. The coke is dry-cooled by gases which absorb the heat and are afterwards used in the combustion of the coke.

**Utilizing waste heat from coke ovens for other carbonization processes.** NAAM-LOOZE VENNOOTSCHAP SILICA EN OVENBOUW MIJ and W. HIBY. Brit. 298,547, June 30, 1927. Heat contained in the hot coke discharged from coke ovens or like app. is used (suitably for low-temp. carbonizations) for the carbonization of materials such as coal, lignite, peat, or wood, by bringing the materials into direct contact and afterward sepg. by screening or otherwise (or the mixt. may be used as a composite fuel without sepn.). The process may be used to obtain semi-coke dust, 15-25% of which may be mixed with a coking coal to improve the quality of coke or which may be used for making briquets. An app. is described.

**Apparatus for mixing coke with wet coal.** ILLINGWORTH CARBONIZATION CO., LTD., and S. R. ILLINGWORTH. Brit. 298,658, June 15, 1927.

## 22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

**Petroleum refineries in the United States, January 1, 1929.** G. R. HOPKINS AND E. W. COCHRANE. U. S. Bur. Mines. *Bur. Mines Circ.* 6116, 21 pp. (1929). E. H.

**A method of distinguishing American from Russian petroleum.** THEODORA P. RAIKOVA. *Z. anal. Chem.* 77, 42-6 (1929).—American kerosene reacts with  $I_2$  in the presence of  $HNO_3$  almost instantaneously, whereas the Russian product reacts very slowly. The following qual. test is proposed. Take 2 cc. of 0.2%  $I$  in  $CHCl_3$ , 2 cc. of 20% aq.  $NaNO_2$  soln. and 2 cc. of the kerosene. Shake well and add 9  $N$   $H_2SO_4$  until the  $I_2$  color of the mixt. disappears or, if that does not take place, until further addition of acid causes no further evolution of nitrous fumes. With American kerosene, the  $I$  color will disappear after the addition of a few drops of acid but it will persist for hrs. in the Russian product. Expts. to det. which fraction of the American kerosene contains a substance that reacts with the  $I_2$  led to the surprising discovery that every fraction of the distillate reacted.

W. T. H.

**Some experiments on vacuum distillation.** C. R. BURCH. *Proc. Roy. Soc. (London)* A123, 271-84 (1929).—Products of petroleum of very high mol. wt. can be distd. without decompn. by the method of evaporative distn. used by Brönsted and Hevesy to sep. isotopes of Hg. A condensing surface is placed a short distance above the evapg. liquid so that the vapor mol. makes no collision during its passage to this surface. The still is shown by a diagram. Dissolved gases are removed by reducing the pressure in stages and by heating, to prevent splashing the condensing surface by bursting gas bubbles. Ordinary distn. is compared with evaporative distn. from a theoretical point of view. A lubricating oil from viscous fuel oil distd. between 300° and 360° at 25 mm. pressure, a cylinder-oil fraction steam-distd. at 345°, a heavy machine-oil fraction produced at 335°, petroleum jelly, pump oil and common paraffin wax were distd. without decompn. Petroleum derivs. of extremely low vapor pressure are prepd. which can be used instead of Hg in condensation pumps in high-vacuum systems ( $10^{-6}$  mm.) with ground joints.

**The practical significance of the various crystalline forms of paraffins in the production of paraffin wax.** E. PYHÄLÄ. *Metallbörse* 18, 2134-5, 2248-9 (1929); cf. C. A. 23, 2282.—The Scotch method of dry-sweating crude paraffin wax is successful only if the crystals have the needle form.

G. CALINGAERT

**The nature and properties of fuel oil.** J. S. SCHOFIELD. *Blast Furnace & Steel Plant* 17, 721-3 (1929).

E. H.

**Natural emulsions in crude oils from Boryslaw-Tustanowic.** I. TADRUSZ KUC-

ZYNSKI. *Przemysl Chem.* 11, 188-97(1927); cf. *C. A.* 23, 1255.—In natural crude-oil emulsions, the sign of the charge on the water droplets depends only on the reaction of the water. If the reaction is acid, the charge is positive; if alk., neg. A. C. Z.

**Thermal transference in transformer oils.** ANON. *J. Inst. Elec. Eng.* (London) 67, 527-37(1929).—An investigation was made of the cooling power of transformer oils when used without forced flow and an attempt to correlate the cooling power with the phys. properties of the oil. Attention was given to the temp. rise of the oil and to that of the windings. Classification according to temp. rise of the oil does not necessarily rank the oils in the same order as classification according to temp. of the windings. The combination of variables,  $ac/v$ , is important;  $a$  is the coeff. of expansion,  $c$ , the heat capacity of unit vol. and  $v$ , the kinematic viscosity. The temp. rise of the windings differs from that of the oil, because it is influenced by the thermal cond. of the oil, an influence greater, probably, than the influence of the combination of properties,  $ac/v$ . Conclusion: To produce the best cooling effect, an oil should have high sp. heat, coeff. of expansion, and thermal cond. and low viscosity. Four oils were tested. The app. and the exptl. methods are described and curves and tables are given. W. H. BOYNTON

**Charcoal production methods in the United States.** K. N. CEDERQUIST. *Tek. Tid., Uppl. C (Kemi)* 58, 45-8(1928).—A illustrated review presenting a detailed report on a study travel made in 1927. C. A. ROBAK

**Industrial extraction of acetic acid from dilute solutions.** S. P. NASAKIN. *J. Chem. Ind.* (Moscow) 5, 1149-57, 1369-76(1928).—Acetic acid obtained in the distn. of wood is best extd. by org. solvents that are insol. in  $H_2O$  and boil considerably lower or higher than  $AcOH$ . Ether is not suitable on account of large loss, fire danger, etc. N. proposes as a new solvent, a fraction from crude wood alc. and coal tar. It consists of 80-85% of esters of lower fatty acids and low-boiling alcs., the remainder being ketones. Its  $d_{20}^4$  is 0.905-0.920, b. 50-70°, soly. in dil.  $AcOH$  11-15%,  $AcOH$  extn. coeff. 0.52-0.57%, heat of evapn. 100 cal. Excellent results were obtained with this solvent in lab. tests; expts. are now being made on a factory scale. Numerous drawings of app., diagrams, tables and calcs. are included. BERNARD NELSON

**Petroleum.** PAUL DVORKOVITZ. Fr. 648,705, Feb. 13, 1928. Petroleum is extd. from bituminous material by a preliminary distn. to remove part of the org. material followed by an extn. with a liquid or vapor solvent which will dissolve the remaining org. material. Thus, bituminous coal contg. 30% org. material is heated to 500°, and 20-40% gas tar or petroleum is then added to dissolve out the remaining org. material.

**Treating petroleum residue.** JULIUS MODERN, FRITZ NEUBER and FRIEDRICH ZIFFER. Austrian 112,441, Oct. 15, 1928. The extn. of lubricating oils from petroleum residues by means of solvents is improved by adding powd. stone to the residues. This addn. facilitates the extn. and also gives a final residue suitable for use as paving material.

**Subdividing paraffin or similar materials.** HAROLD GROSSMAN. U. S. 1,711,482, April 30. The material is melted and formed into a hot emulsion with an aq. liquid contg. about 2% of Na oleate, HCl is added to the emulsion and the emulsified material is pptd. in the form of fine particles by mixing the emulsion with water.

**Separating paraffins from liquid hydrocarbons.** N. O. BACKLUND (to Aktiebolaget Separator-Nobel). Swed. 64,383, Jan. 4, 1928. Asphalts which impede the crystn. are first eliminated by centrifugalizing; then the paraffins are sepd. By this procedure the paraffins can be more completely removed from highly viscous oils and the output of high-grade lubricating oils is increased. Cf. C. A. 23, 1136.

**Apparatus for the destructive distillation of bituminous materials.** ELEKTROWERKE A.-G. Ger. 472,657, Feb. 13, 1924. Details of arrangement.

**Catalytic oxidation of hydrocarbons.** I. G. FARBENIND. A.-G. Brit. 298,704, July 22, 1927. Oxidation of paraffin or similar hydrocarbon materials with O-contg. gases such as air is effected in the presence of inorg. catalysts such as metals, metallic oxides or salts, including salts of org. acids, and may be accelerated by the conjoint use of org. nitrogenous bases such as  $(CH_3)_3N$ , aniline, pyridine, quinoline, toluidine, butylamine, amylamine and hexylamine, which may be used with substances such as Mn soap, Ce oxide or Ce stearate. The products consist mainly of mixts. of aliphatic carboxylic acids, alcs. and esters. Cf. C. A. 23, 1364.

**Apparatus for pressure cracking of liquid hydrocarbons.** SAMUEL J. M. AULD, ALBERT E. DUNSTAN and PERCY H. HERRING (to Anglo-Persian Oil Co., Ltd.). U. S. 1,711,219, April 30. An app. is described comprising a preheater, a plurality of sep. and relatively short "thermalizing tubes" into which the liquid passes from the preheater, a "reactor" surmounting the thermalizing tubes into which the liquid passes from the latter, and a setting in which this app. is mounted. The thermalizing tubes are placed within a flue of the setting and may be subjected to a regulated heating and valves are provided in a wall of the setting which serve for regulating the flow of heating

**Cracking hydrocarbons.** STANDARD OIL DEVELOPMENT CO. Fr. 649,348, Feb. 21, 1928. A current of petroleum oil is heated to cracking temp. in a single passage through a heating zone, the heated oil passing to a digestion zone in which part, at least, of the oil vaporizes and is partly condensed. The condensate is mixed with the oil passing from the heating to the digestion zone, the amt. of condensate being sufficient to regulate the temp. in the digestion zone. An app. is described.

**Cracking hydrocarbon oils.** S. M. NORWOOD (to Electro Metallurgical Co.). Brit. 298,556, Oct. 11, 1927. Cracking is effected in an app. made of, or lined with an alloy contg. Cr 15-40, Ni 2-15, Si 0.7-3.0, Mn 0.7-3.0% and the remainder mainly Fe, with not more than 1% C.

**Cracking hydrocarbon oils.** EDWARD W. ISOM (to Sinclair Refining Co.). U. S. 1,711,351, April 20. Oil is heated in the vapor phase to a high cracking temp. and, before condensation of the desired lighter oil of lower b. p., the vapors from the cracking operation are subjected to a fractionation in which there is introduced into direct contact with the vapors, as a cooling and condensing agent, an oil of boiling range corresponding to that of the desired lighter oil of lower b. p. but substantially free from unsatd. components unstable at the temps. prevailing in the fractionating operation. An arrangement of app. is described. Cf. C. A. 23, 2566.

**Apparatus for cracking oils, etc.** PETROLEUM PROCESS CO. Fr. 648,832, June 28, 1927. The oil is caused to descend in an ascending current of gaseous heating agent.

**Distillation of heavy oils.** LEO STEINSCHNEIDER. Austrian 112,348, Oct. 15, 1928. See Brit. 264,476 (C. A. 22, 163).

**Extracting oils from sands.** STANDARD OIL DEVELOPMENT CO. Fr. 649,571, Feb. 22, 1928. Oils are extd. from sands contg. them by displacement by means of electrolytes such as  $Na_2CO_3$ ; an effective concn. is maintained during its passage through the sand by the introduction of concd. soln. at the sides. A suitable app. is described.

**Oil-gas-producing apparatus.** AUGUST SCHILLING, RICHARD SACHSE, DIMITRI LIAMIN and THEOPHIL CALLAERT. U. S. 1,710,900, April 30. The gas-generating chamber is provided with a checkered hearth from which a wall of refractory material rises concentrically, dividing the interior into concentric chambers; near its base the wall is provided with apertures affording communication between the chambers, and a combustible mixt. of oil, air and steam is discharged axially in a downward direction into the inner chamber and toward the checkered hearth. A jet stream of oil and steam is delivered against the outer surface of the refractory wall above the apertures, and gases produced are withdrawn through the checkered hearth. Various structural details are described.

**Hydrocarbon oils.** I. G. FARBERIND. A.-G. Brit. 299,086, July 21, 1927. Oils of high viscosity and flash point suitable for use in the production of lubricating oils are obtained by passing gases rich in lower olefins such as  $C_3H_6$ ,  $C_4H_8$ ,  $C_5H_{10}$ , and  $C_6H_{12}$  (which may be obtained by cracking tar or mineral oils or as a by-product from other industrial processes) into hydrocarbon mixts. which are liquid at ordinary temps., in the presence of catalysts of the Friedel-Crafts type such as  $AlCl_3$ ,  $ZnCl_2$ , or  $FeCl_3$ , the action of which may be improved by the further addn. of  $HgCl_2$  or uranyl chloride. Temps. up to  $200^\circ$  are suitable. Various details and modifications are described.

**Mineral oils.** ADOLPHE A. F. M. SEIGLE. Ger. 472,734, Dec. 20, 1922. A plant for distg. and sepg. mineral oils and similar hydrocarbons is described.

**Lubricants.** GEORG SCHICHT. Austrian 112,631, Nov. 15, 1928. Products useful as lubricants are obtained by heating drying oils in the presence of mineral oils or like hydrocarbons to above  $200^\circ$  until a satd. but still sol. product is obtained. The drying oils may be partly polymerized or oxidized before treatment.

**Bituminous emulsions.** CHEMISCHE FABRIK BUCKAU. Brit. 298,842, Jan. 26, 1928. Bituminous substances are emulsified by use of "boron acids in alk. soln." (such as a soln. formed from  $H_3BO_3$  and caustic alkali) in a quantity of 2% or less of the finished emulsion.

**Furnace for carbonizing wood and recovering by-products.** ÉMILE TRIHAN. Fr. 648,756, Dec. 22, 1927.

## 23—CELLULOSE AND PAPER

CARLETON E. CURRAN

The estimation of alpha-cellulose. CARL G. SCHWALBE. Forstl. Hochschule, Eberswalde, bei Berlin. *Pulp Paper Mag. Can.* 26, 1863-4(1928); 27, 11-3, 41-2(1929); *Paper Trade J.* 88, No. 3, 61-5(1929).—See C. A. 23, 699. A. PAPINEAU-COUTURE

Determination of  $\alpha$ - and of  $\beta$ -cellulose. RAGNAR BERGGVIST. *Svensk Pappers-Tid.* 31, 814-8(1928); cf. C. A. 22, 1678.—From a critical study of the Jentgen method for detg.  $\alpha$ -,  $\beta$ -, and  $\gamma$ -cellulose compared with a parallel detn. of a control sample of known compn. B. concludes that with certain precautions the Jentgen method gives results which do not need the usual corrections. B. suggests the following precautions: The analysis should be conducted in a thermostat at  $20^\circ$ , or a correction of 0.1% to the  $\alpha$ -cellulose value should be added for each degree under  $20^\circ$  and subtracted for each degree above  $20^\circ$ ; an equal but reverse correction should be applied to the  $\beta$ -cellulose value; the temp. of the wash water should be kept at  $20^\circ$ . Washing and filtering must be done as rapidly as possible after diln., and a Büchner funnel is recommended. Dilution with water between the mercerizing and filtering should always be done with the const. quantity 300 cc. Grinding of material should be done with light blows and 5 mins. pounding should suffice. Careful work along the above lines should give an  $\alpha$ -cellulose content value with an error not greater than  $\pm 1\%$ . WILHELM SÖGERBLOM

Cellulose from cornstalks. H. A. WEBBER. Iowa State College, Ames, Iowa. *Ind. Eng. Chem.* 21, 270-5; *Paper Mill* 52, No. 1, 4, 6, 8; No. 2, 24-5(1929).—A review of the structure and chem. compn. of the corn plant, with a brief summary of the work carried out at Iowa State College on the economic possibility of producing sufficient cellulose of satisfactory quality from cornstalks. The NaOH cooks give best results when everything is considered, although pulps made with halogens require less bleach. In general, the bleach consumption of the NaOH cooks amounts to 20% of the wt. of the dry pulp and there is a loss of about 10% of the pulp during the bleaching process, or about 3-3.5% of the original wt. of stalk, giving an over-all yield of good paper-grade pulp amounting to 30-32% of the original wt. of the stalks, with an  $\alpha$ -cellulose content of 70-75%. The soda, kraft and halogen processes make pulps suitable for magazines, books and writing paper; the lime-soda and sulfite processes give a weaker paper, suitable perhaps for toilet paper and similar grades; while the lime pulp seems suitable for boxboard and similar grades where an unbleached pulp can be used. Cornstalks are more easily reduced to pulp than are woods, but they are more bulky, and give lower yields of cellulose which requires slightly more bleach. The fibrous outer shell used alone makes the strongest paper; the pith used alone gives a translucent parchment-like paper; while paper varying between these two extremes is obtained when the entire stalk is used. The pulp made from the fiber requires less bleach than that from the pith, although the fiber is more colored in the raw state. The leaves and husks produce the weakest paper. When the entire stalk is used, a good paper can be produced if the cook is relatively short (1.5-2 hrs.) and the beating is not too severe, as in this case the entire

pith is not reduced to a colloidal condition, but some of it is drawn out into fibrous forms which interweave with the more resistant fibers. A. PAPINEAU-COUTURE

**Chemical examination of the tissue of the cornstalk.** C. J. PETERSON AND R. M. HIXON. *Ind. Eng. Chem., Anal. Ed.* 1, No. 2, 65-7 (1929).—Examn. of cornstalk for chem. constituents showed it to contain primarily lignin, pentosans and cellulose in the approx. amts. of 30, 27 and 36%, resp. Alk. hydrolysis caused the soln. of approx. 46% of the stalk, of which lignin and hemicelluloses constituted approx. 27 and 17% (based on stalk), resp. Acid hydrolysis dissolved approx. 41% of the stalk, of which lignin and hemicelluloses constituted approx. 14 and 26% (based on stalk), resp. Pectin or pectic acid could not be definitely identified. Three structural tissues, shell, pith and vascular bundles, each having characteristic phys. properties, were sepd. from the stalk and by chem. analysis found to be practically identical with the entire stalk. E. R. SCHAFER

**The x-ray diagram of cellulose.** R. O. HERZOG AND W. JANCKE. *Z. physik. Chem., Abt. A*, 139, 235-62 (1928).—Examg. various natural and hydrated celluloses H. and J. detd. that the cellulose crystallites have their principal axes in the fiber axis, or with a spiral fiber, tangential to the spiral. The slopes of the spirals agree, within the exptl. error as indicated by double refraction, with striations or cleavage of the crystals disclosed through microscopical data. The diagrams of all natural celluloses are the same while those of the products resemble that of hydrated cellulose. The differences are explained by the existence of 2 modifications of cellulose in which possibly the natural cellulose crystallizes in the monoclinic system and the hydrated cellulose in the rhombic system. Natural as well as mercerized fibers show fiber diagrams with the same periodicity in the fiber direction. On doubling the *a*-axis of natural cellulose, assuming  $(C_6)_8$  as an elementary body, all points fitted into a quadratic form. The same was true of the hydrated cellulose when the *b*-axis was doubled. According to Weissenberg the micro-building unit is at most half the wt. of the elementary body. The formulas for natural and hydrated cellulose are the same when both horizontal axes are doubled. Here the elementary body contains 16  $(C_6)$ -groups. It is thought that the micro-building units, the largest stoichiometrical groups, are parallel to the fiber axis, and linked to one another according to a diagonal screw-axis and so form a chain building-unit. The chem. problem is whether this linkage occurs through a principal valence (chain theory of valence) or a secondary valence (van der Waals' force theory). Some of the theories of this linkage are given. Cellobiose anhydride gives a diagram similar to the cellulose hydrates; also those of acetyl- and methylcellulose show no difference when compared with acetyl- and methylbiocellulose anhydride. The authors believe that the proof for the cellulose formula is essentially whether one and the same chain building-unit is present as an individual group and how the mutual ratio of these building units in the anhydride differ from that in the cellulose, and that research on other phys. properties is required to solve the problem. F. A. SIMMONDS

**The oxidation of cellulose under the influence of light.** II. V. V. SHARVIN AND A. PAKSHVER. *Z. angew. Chem.* 41, 1159-61 (1928).—When cotton fabric that has been bleached, ether-extd., washed and dried is sealed in a glass tube in an atm. of dry  $CO_2$  and placed in the sunlight, there is at first a simultaneous formation of oxycellulose,  $CO_2$  and  $H_2O$ . The amt. of  $CO_2$  formed bears a definite relation to the amt. of oxycellulose formed but, as yet, this cannot be expressed by a const. stoichiometrical proportion. Upon continued exposure to the light, there is a gradual decrease to no  $CO_2$  formation while the oxycellulose oxidizes further. Besides  $CO_2$  and  $H_2O$ , compds. are formed that have an odor resembling furfural, but do not give furfural reactions. There is a loss of wt. and strength in the fabric. When the  $O_2$  is replaced by  $N_2O$ ,  $CO$ ,  $NH_3$  or  $H_2$ , there is no oxycellulose or  $CO_2$  formed. If, however, cotton dyed with an organic dye is placed in the sunlight in an atm. of O-contg. gases ( $NO$ ,  $N_2O$ , etc.),  $CO_2$  is formed as a product of the oxidation of the dye. C. E. HRUBESKY

**The reaction of cellulose with phenylhydrazine.** C. J. STAUD AND H. LEB. GRAY. *Ind. Eng. Chem., Anal. Ed.* 1, 80-1 (1929).—A comparison is made between the Cu no. and the phenylhydrazine no. as methods for evaluating the amt. of reducing substances in a cellulose. There is a general trend of agreement between the methods but the phenylhydrazine no. appears to give the better index. F. A. SIMMONDS

**Studies on cellulose and its derivatives.** J. J. TRILLAT. *Rev. gén. colloïdes* 6, 177-92 (1928); cf. *C. A.* 23, 971.—X-ray spectrography was used to study different transformations of cellulose and the phenomena of acetylation. Cellulose, oxycellulose and hydrocellulose give identical diagrams except that different orientations are observed. Hydro- and alkali-cellulose yield different results. The cellulose form is changed into the hydrocellulose form each time that it undergoes swelling (acetylation followed by sapon., viscose silk, etc.). The study of acetylation indicated that the

structure of the acetylic compds. varied with the proportion of fixed AcOH. Also cryst. and amorphous phases were detected. It is possible to calc. the approx. dimensions of the elementary groupings comprising the solid colloidal gel. A good description of the app. is given. The radiations employed were the K  $\alpha$ -rays of Cu and Cr.

F. A. SIMMONDS

**Action of light on celluloid stained with malachite green.** RAYLEIGH. *Nature* 122, 645-6(1928).—Celluloid stained with malachite green acts as a light filter according to the relative time of exposure to sunlight. When new, it passes wave lengths of 4750-5700 A. U. and 6900-7500 A. U.; upon prolonged exposure, wave lengths of 6250-7500 A. U., while the intermediate stage passes those of 6830-7500 A. U. By making up various films dyed with malachite green R. finds that the phenomenon is due to some definite reaction between nitrocellulose and the dye.

F. A. SIMMONDS

**Cellulose formate. II. Formation of cellulose formate.** Y. UYEDA AND K. KATO. *Cellulose Ind.* (Tokyo) 4, 203-205(1928); cf. C. A. 22, 4792.—Cellulose formate is prepd. from regenerated cellulose, 100% formic acid, and H<sub>2</sub>SO<sub>4</sub>. The formic acid content of the ester increases with the reaction period to a max. and subsequently decreases. Similar variations occur with increasing proportions of H<sub>2</sub>SO<sub>4</sub>. In both cases the max. figures are slightly below the theoretical for the triformate.

B. C. A.

**Allylcellulose.** ICHIRO SAKURADA. Kyoto Imp. Univ. *J. Soc. Chem. Ind.* (Japan) 31, 638-42; Supplemental Binding 31, 157B(1928).—By treating tissue paper with 40-50 vol. % NaOH soln. and allyl bromide, the higher cellulose-allyl ethers (tri- and di-ether of C<sub>6</sub> unit) were directly obtained. The halogen absorption power of the resulting ether was quite concordant with the result of elementary analysis, and it has been ascertained that the double bond remains quite intact in the above etherification treatment. The tetrabromide of cellulose-diallyl ether was isolated in almost pure state. The higher allyl ether is partly sol. in alc., C<sub>6</sub>H<sub>6</sub> and CCl<sub>4</sub> but its soly. is not so great as would be expected.

Y. TOMODA

**The hemicellulose of spruce wood and its condition during sulfite digestion.** ERIK HAGGLUND. *Svensk Pappers-Tid.* 31, 572-6(1928).—H. compares critically the methods used by Schulze, Klingstedt, König and Becker, Thomsen, Heuser and Schmidt for sepg. and detg. hemicellulose. The detn. of sugar is rendered unreliable because of incomplete pptn. by  $\alpha$ -naphthylamine sulfate, and of passage of part of the lignosulfonic acid with the sugar through the dialysis membrane. The method used by H. for purifying the sugar soln. and detg. the substances present therein is described in detail. The easily hydrolyzed part of spruce hemicellulose contains pentoses 17, mannose 42.7, galactose 4.2, galactonic acid 3.2, fructose 4.0, glucose 28.9%. Not all the hemicellulose goes into soln. during the sulfite digestion. Of the approx. 50% yield of strong sulfite pulp from the wood only about 80% is pure cellulose; the remainder is lignin and the more difficultly hydrolyzed hemicellulose. Errors in prevailing methods for examg. the difficultly hydrolyzed part of spruce hemicellulose are pointed out and suggestions made for obviating these errors. Sulfite cellulose contains lignin 4.4, ether-sol. part 1.0, ash 0.4, carbohydrates 94.2%. The compn. of spruce wood, based on the improved hemicellulose methods, is cellulose 41.5, hemicellulose 24.3, lignin 28.0, AcOH, etc., 2.3, resin, ash, protein and undetd. 3.9%. The hemicellulose is made up as follows: (1) easily hydrolyzed part: mannose 2.9, xylose 2.2, fructose 1.2, sum 6.3%; (2) difficultly hydrolyzed part: mannose 7.7, glucose 5.2, galactose, 0.7, fructose 0.7, xylose 3.1, galactonic acid 0.6, sum 18.0%; total hemicellulose 24.3%. The actual cellulose content in spruce wood is therefore smaller than usually thought. During digesting of strong sulfite pulp the hemicellulose divides itself so that three-quarters go into soln. and one-quarter remains in the pulp. The relation of the above investigation to mercerizing is discussed. H. concludes that the lignin is chemically combined with the carbohydrates in the wood rather than being mechanically mixed therewith. W. SEGERBLOM

**Cellulose-xanthogenamides.** TADASHI NAKASHIMA. Kyoto Imp. Univ. *J. Soc. Chem. Ind.* (Japan) 31, 629-33; Supplemental Binding 31, 155B(1928).—Cellulose-xanthogenamides were obtained by the interaction of the Na salt of cellulose-xanthogenacetic acid and NH<sub>3</sub> or amines. The analyses of the products are given. Y. TOMODA

**Relation between swelling, salt formation and microstructure in the cellulose fiber.** C. TROGUS. Kaiser-Wilhelm Inst. Chemie. *Papier-Fabr.* 27, 55-60(1929).—A discussion correlating x-ray, microscopic and chem. studies on normal and mercerized cellulose and artificial fibers. Illustrations and numerous references are included.

R. H. DOUGHTY

**Manufacture and properties of regenerated cellulose films.** WM. L. HYDEN. *Ind. Eng. Chem.* 21, 405-10(1929).—The history and manuf. of cellophane are described and the reactions occurring in prepn. of alkali-cellulose, aging, xanthation and ripening

are discussed. Cellophane possesses certain phys. properties such as strength, permeability, optical, dielectric and physiol. properties which adapt the material to a no. of varied uses.

E. R. SCHAFER

**Acetylcellulose film and its fiber.** I. Relation between the quality of acetylcellulose and its film strength. G. KITA AND G. KANNO. Kyoto Imp. Univ. *J. Sec. Chem. Ind. (Japan)* 31, 730-2; Supplemental Binding 31, 176-7B(1928).—The acetylcellulose obtained by acetylation at 25° gave a weaker film than those obtained by acetylation at lower temps. It is not always true that the acetylcellulose of higher viscosity gives a weaker film. II. Relation between the conditions of film preparation and the quality of the resulting film. G. KITA AND G. KANNO. *Ibid* 733-8; Supplemental Binding 31, 177-8B(1928).—In prepn. of acetylcellulose film, the optimum pressure during the solvent evapn. is about 70 cm. of Hg, and the optimum concn. of acetylcellulose (in acetone soln.) is about 12%. The influence of diluents such as H<sub>2</sub>O and C<sub>6</sub>H<sub>6</sub> in the acetone soln. upon film quality has been examd. III. Spinning of acetylcellulose fiber. G. KITA, T. UEMATSU AND S. MASUDA. *Ibid* 739-45; Supplemental Binding 31, 178-9B(1928).—Exptl. results of dry spinning of acetylcellulose are described.

Y. TOMODA

**Characterization of spruce wood for groundwood and for cellulose.** E. MORK. *Papir-Journalen* 16, 40-4, 54-8, 64-9, 79-83, 88-91, 101-4, 111-4(1928).—The author's purpose is to attempt to show anatomical differences in the structure of the wood in different parts of the tree and in annual rings of various widths in order to account for the greater dry weight and consequently higher yields of wood with narrow annual rings. From a study of the % of summerwood, the fiber length and the fiber thickness on 5 specimens of spruce it was found that (1) other conditions being equal, wood with narrow annual rings has a higher percentage of summerwood and contains longer fibers than wood with broad rings, except that in the case of rings of less than 1.0 mm. width deviations from this rule may be found; (2) there is no regularity in the relation between width of annual rings and cell wall thickness and there is no indication that broad rings have larger cell spaces. Since summerwood yields the same amount of pulp as springwood on a weight basis (according to Kinman) it is evident that wood with narrow annual rings and having as high as twice the percentage of summerwood as wood with broad annual rings will yield more pulp per cord.

C. E. PETERSON

**New investigations in wood and cellulose chemistry.** ERIK HAGGLUND. Univ. of Åbo, Finland. *Tek. Tid., Uppl. C (Kemi)* 58, 25-8(1928).—By the regeneration of black (sulfate) liquor by means of the high-pressure decompn. method a substance which resembles pitch is obtained in amts. of about 25% of the wood weight. It has been proved that this substance can be almost completely converted into oils of different b. ps. by means of high-pressure hydrogenation in the presence of catalysts. The output of bleached alk. pulp from coniferous woods will usually be low, at best about 40%, because the usual bleaching methods are not applicable to pulp produced with a higher yield. Expts. have shown that it is possible to bleach distinct kraft pulps obtained with a yield of 50% and more to complete whiteness under maintenance of a high mech. strength with a total consumption of 15% Cl and an output of 45-7% of bleached pulp. The chemistry of the sulfite cellulose boiling processes has been studied, particular interest being taken in the question of the sulfonation of lignin isolated by means of highly concd. HCl. It is a well-known fact that this lignin is not readily dissolved by sulfite liquor. The expts. have not verified the statement of Kirschnner that the reaction of soln. is accelerated by the presence of cellulose. By examg. the lignosulfonic acid obtained in soln. it was found to be quite different from that obtained by direct decompn. of spruce wood, particularly as regards the S content which in the former is slowly increasing to about 50% above the usual value. The low soly. of HCl-lignin is explained by assuming that it is present in a highly assocd. form. The stability conditions of the sulfite in the boiling liquid have been studied and it was found that sugars, too, can considerably accelerate the decompn. of the sulfite. Two liquids, contg. 1% Na<sub>2</sub>O and 4% SO<sub>2</sub>, one with, the other without, an addn. of 2 g. sugar per 100 cc. were heated to 135°. After 4-5 hrs., after the max. temp. had been reached, a rapid decompn. of the sulfite was observed in the liquid contg. sugar while in the sugar-free liquid no appreciable decompn. could be noticed. Extensive investigations of the method of digesting wood with aq. SO<sub>2</sub> alone at low temps. gave only unfavorable results. Even at the low boiling temp. of 90° it was observed that the solid lignosulfonic acid present in the wood is undergoing a resinification and dark-coloring. The method is not likely to have any practical importance. The so-called Keebra method of boiling red fir wood (*Pinus sylvestris*) has been examd. according to the patent description. Heart-wood of red fir was boiled for 4 hrs. with a soln. of Na<sub>2</sub>SO<sub>3</sub>, 40% of the wood

weight, at 8.5 atm. and the residue was boiled again for 4 hrs at the same pressure with a liquid contg. 25%  $\text{Na}_2\text{SO}_3$  and 3%  $\text{NaOH}$ . The weight of the wood was reduced to about 55% of the original but the residue still contained 19.2% lignin and consisted in solid chips, no usable pulp being obtained.

C. A. ROBAK

**Pine-wood lignin.** ERIK HÄGGLUND AND HELMUT URBAN. Inst. für Holzchemie, Academie Abo. *Biochem. Z.* 207, 1-7(1929).—Lignin prepd. by brief action of concd.  $\text{HCl}$  on pine wood freed from resins still contains considerable amts. of carbohydrates that can be removed without injury to the material by boiling for 1-2 days with 4-5% mineral acid. Ligninsulfonates yield on distn. by the Tollens method substances which form condensation products with barbituric acid. Am or Pr lignin prepd. either from wood or from  $\text{HCl}$ -lignin or from  $\text{AcOH}$ -lignin yields practically no  $\text{HCHO}$  in the Tollens distn. No  $\text{HCHO}$  is split off in the prepn. of lignin by  $\text{AmOH}$  and no  $\text{AcOH}$  by piperonylic acid. In the reaction with  $\text{AmOH}$  the  $\text{HCHO}$  is converted into diamyl methylal.

S. MOROGLIS

**Viscose. V. Quality of caustic soda, manufactured in Japan, from the point of view of the viscose industry.** M. NUMA. *Cellulose Ind.* (Tokyo) 4, 82-94(1928); cf. C. A. 21, 3458; 22, 2055.—The dissolving power of  $\text{NaOH}$  for the modified cellulose contained in pulp is diminished by the presence of  $\text{Na}_2\text{CO}_3$ . Small quantities of both  $\text{Na}_2\text{SO}_4$  and  $\text{NaCl}$  behave catalytically in assisting soln., but in large quantities their action is deleterious; the presence of sulfate, even in small quantity, renders the viscose film brittle. More than half the total quantity of  $\beta$ -cellulose in the original pulp is retained by the alkali cellulose after removal of the excess  $\text{NaOH}$ . The most satisfactory film is given by use of a  $\text{NaOH}$  soln. contg. the min. amts. of carbonate and sulfate and no insol. impurities such as alumina, Fe, silicates, etc.  $\text{NaCl}$  present to the extent of 3-5% has a beneficial effect on the film. Specifications for the compn. of  $\text{NaOH}$  to be used in the production of viscose are laid down. VIII. Effect of dialysis in relation to viscosity. T. MUKOYAMA. *Ibid* 109-12.—Viscose soln. (cellulose 4.03%, alkali 3.74%) which had ripened for 24 hrs. was subjected to dialysis, water or varying concns. (up to 6%) of caustic soda being used in the dialyzer. With water alone the viscose rapidly gelatinized, but with increasing concns. of caustic soda the viscosity of the viscose soln. fell progressively. X. G. KITA, R. TOMIHISA, K. SAKURADA AND H. KONO. *Ibid* 3, 27-31(1927); cf. C. A. 21, 2383.—The influence of the temp. in the prepn. and maturing of the alkali-cellulose was studied. The viscose from alkali-cellulose treated at  $25^\circ$  is easily spread on a glass plate, but the film becomes detached in the setting bath, whereas the viscose from alkali-cellulose prepd. at  $0^\circ$  is not easily spread. The tenacity and especially the extension of the film are adversely affected by storage of the alkali-cellulose at  $25^\circ$ , whereas they are not affected by storage at  $0^\circ$  and in both cases they increase similarly to a certain extent during the ripening of the viscose. With alkali-cellulose treated at  $8-10^\circ$  the viscose ripened at  $0^\circ$  is not easily spread, and requires some time in the setting bath, giving a white translucent film, whereas viscose ripened at  $20^\circ$  is readily coagulated, giving a semi-transparent film. Ripening at  $20^\circ$  induces spontaneous coagulation of the viscose after 5 days. When the viscose is ripened at  $0^\circ$  the tenacity and extension do not as a rule increase with the time of ripening. Alkali-cellulose aged for 5 days gives the highest results. Ripening the viscose at  $20^\circ$  gives films equal in tenacity and extension to those from viscose ripened at  $0^\circ$ . Alkali-cellulose prepd with 13% caustic soda lye gives inferior films to that prepd. with 25% or 30% lye; the viscose does not spread easily; the films are less transparent; and the tenacity and extension are poor. XI. G. KITA, R. TOMIHISA, K. SAKURADA, Y. NAKAMURA AND H. KONO. *Ibid* 117-25.—Viscose contg. 6% of cellulose was spun into a coagulating bath contg. 17.5% of  $(\text{NH}_4)_2\text{SO}_4$ , 8% of  $\text{H}_2\text{SO}_4$  and 7.5% of glucose, the influence of the time of aging of the alkali-cellulose and ripening of the viscose and the alk. of the viscose being studied. The viscose from alkali-cellulose aged only for a short time spins more easily under a high pressure, whereas that from more seasoned alkali-cellulose spins under a lower pressure. The viscose spins more easily as its ripening advances. The ease of spinning is measured by the speed; a speed of 57 m./min. is not easily obtainable when the alkali-cellulose has been aged for too short or too long a time, but is readily obtained with viscose from moderately aged alkali-cellulose. With the same viscose, differences in tenacity and elongation of the thread may be produced by differences in spinning speed and pressure owing to variations in the coagulation conditions, i. e., the velocity of the action of the bath on filaments of different thickness. The tenacity and elongation increase with the times of aging of the alkali-cellulose and ripening of the viscose up to a certain point, beyond which they remain constant or decrease slightly. It would not be right, however, to conclude that the increase in tenacity and elongation is dependent on the decrease in viscosity of the viscose which takes

place at the same time. XII. G. KITA, R. TOMIHISA, K. NAKAHASHI AND J. ONOHARA. *Ibid* 265-73.—In the progressive stages of ripening, the capacity of the viscose to give a continuous thread varies with the temp. of the coagulating bath between 30° and 60° in the sense that the ability to spin at the lower temps. covers a much smaller range of ripeness than at the higher temps. With under-ripe viscose this is due to difficulty of coagulation, whereas with over-ripe viscose, with rapid coagulation the threads become too fine to withstand the tension. A high temp. lowers the viscosity and facilitates the extrusion, but at the same time it increases the rate of coagulation so that the filaments may be finer. The tenacity of threads from the same viscose is generally greater the finer the filament, but the extensibility varies in the contrary direction. The properties of the thread change with the degree of ripening, for which there is an optimum point. In an  $(\text{NH}_4)_2\text{SO}_4$ -glucose bath, with  $\text{H}_2\text{SO}_4$  ranging from 4 to 12%, an under-ripe viscose first becomes capable of spinning with the higher concn. of acid, and with the higher concns. an over-ripe viscose first ceases to give a thread. The threads spun from under-ripe viscose in strongly acid baths are lusterless and voluminous. A similar relation exists with high concns. of  $(\text{NH}_4)_2\text{SO}_4$  as with high concns. of  $\text{H}_2\text{SO}_4$ , except that the threads spun from under-ripe viscose with strongly saline baths are lustrous; they have also good tenacity. With weaker concns. of  $(\text{NH}_4)_2\text{SO}_4$  the quality of the threads depends more intimately on the attainment of the optimum degree of ripening. XIII and XIV. G. KITA, K. NAKAHASHI, R. TOMIHISA AND J. ONOHARA. *Ibid* 4, 25-30, 31-4 (1928).—By the addn. of glucose, viscose may be spun after a longer ripening than when  $(\text{NH}_4)_2\text{SO}_4$  is used in the bath, while slightly increasing the quantity of glucose shortens the necessary time of ripening. Over-ripe viscose cannot be spun from a bath contg. a large quantity of glucose, the action of the latter being affected by the degree of ripening. For viscose spun from such a bath the tensile strength of the fibers is increased but the extensibility is diminished. In a bath contg. 8% of  $\text{H}_2\text{SO}_4$  a less ripe viscose may be spun than in one contg. much  $\text{Na}_2\text{SO}_4$ , while if 12% of  $\text{H}_2\text{SO}_4$  is used the opposite is the case.  $\text{Na}_2\text{SO}_4$  has no effect on the tensile strength and extensibility of the fibers. No special influence is exerted by  $\text{MgSO}_4$  of 6% concn., while with under-ripe viscose, in the initial stages of spinning, a 12% soln. increases the tensile strength. Fibers from a bath contg.  $\text{ZnSO}_4$  are at first colored yellow, but afterward decolorized. When 1-3% of the salt is present a less ripe viscose may be spun than when no  $\text{ZnSO}_4$  is added, but for a 5% soln. the opposite holds, *i. e.*, a less ripe viscose is more difficult to spin than when the salt is absent. The influence of  $\text{ZnSO}_4$  on the properties of the fibers depends on the properties of the viscose, but with a moderately ripened viscose fibers of increased extensibility and tensile strength may be obtained. XVI. Spinning. 6. Maturing of alkali-cellulose and its effect on spinning and on the properties of the threads. R. TOMIHISA. *Ibid* 113-6. — Alkali-cellulose which had matured at 12°, 20° and 25° for varying periods up to 3 days was xanthated and the resulting viscose solns., after ripening for varying periods, were spun into a bath contg.  $\text{H}_2\text{SO}_4$  10, dextrose 7.5, crystalline  $\text{MgSO}_4$  25.54, crystalline  $\text{ZnSO}_4$  5.34 and water 52.62 pts. at 45°. A study of the phys. properties of the filaments thus obtained indicates that (a) the longer the period of maturing of the alkali-cellulose, particularly at the higher temps., the longer must the viscose soln. be allowed to ripen to make it spinnable and the thicker are the filaments; (b) at the lower temps. the time of maturing of the alkali-cellulose has no great influence on the max. strength of the thread, but at higher temps. the more highly matured alkali-celluloses give a markedly weaker thread; (c) for the production of the strongest threads the alkali-cellulose should be matured for a moderate time at a medium temp.; (d) a less ripe viscose is required for the production of threads of max. stretch than is necessary for threads of max. strength; and (e) of two spinning speeds (23 and 46 m./min.) the higher gave the stronger threads. XVIII. Spinning. 8. G. KITA, R. TOMIHISA AND J. ONOHARA. *Ibid* 235-7.—Results are given showing that by maturing alkali-cellulose in H instead of air the viscose prepd. shows a higher viscosity, is more easily spun, and is capable, after suitable ripening, of giving stronger threads (2 g. per denier). Attempts to produce viscose threads of equal strength by shortening the time of maturing in air to 6 hrs at 25° were not successful. 9. G. KITA, J. ONOHARA AND K. MASUI. *Ibid* 237-41 — The time of maturing of the alkali-cellulose for the production of the strongest viscose threads depends on the duration of the steeping operation. Thus, with a steeping time of 3, 7, 14 days (at 7-11° in each case), the optimum maturing time of the alkali-cellulose at 25° was, resp., 3, 12 and 4 hrs. Under these conditions it is possible to prep. viscose threads of as high strength as is shown by viscose prepd. from alkali-cellulose matured in an atm. of H. B. C. A.

Turbidity and gelatinization of viscose caused by addition of chemicals. T. MUKOYAMA. *Cellulose Ind.* (Tokyo) 4, 170-7 (1928).—A viscose soln. (4.1% of cellulose

and 3.4% of alkali) was treated with various salt solns. and changes in turbidity and rate of gelatinization were examd. The  $\text{NH}_4^+$  ion tends to accelerate turbidity formation and gelatinization proportionally to the concn. used.  $\text{NaCl}$ ,  $\text{Na}_2\text{SO}_4$ , and glycerol are much slower in their action, and their effect is less sensitive to change in concn. Sulfate and sulfite ions restrain the gelatinizing effect of salt, especially when the Na salts are used.

B. C. A.

**New materials for the manufacture of artificial silk.** ANON. *Bull. Imp. Inst.* 27, 1-9(1929).—Results are given of an investigation into the suitability of *bagasse*, *sulfite pulp from Tasmanian stringy-bark* and *Phormium tenax* fiber as sources of cellulose for rayon. Bagasse from Trinidad in the form of fibrous chips and crushed cane in pieces of irregular size up to 5 in. in length contained  $\text{H}_2\text{O}$  10.8, ash 1.2 and cellulose 51.2 (57.4% on the dry basis). The fiber length was 0.6–5.0 mm. (av. 1.95) and the fiber diam. was 0.0152–0.0508 mm. (av. 0.0264). Cooking 3 hrs. at  $140^\circ$  with 20%  $\text{NaOH}$  at a concn. of 3% yield 48% of unbleached pulp, which furnished a pale grayish brown paper of excellent strength, contg. a no. of noticeable fibrous specks, probably derived from the nodes of the cane. With a light bleaching treatment, the yield was reduced to 40% (on the original material) of pulp which furnished a very pale cream-colored paper of similar character and strength to the unbleached paper; the small specks were only partially affected by the bleaching treatment. The paper in both cases exhibited the "rattly" character of paper produced from fibrous material contg. pithy matter. By mech. sepn. of the pith from the fibrous material, it would no doubt be possible to produce paper of very good quality. Cooking as above after removal of 33% of pithy material by mech. treatment yielded approx. 29% (43.5% on the mechanically treated material) of pulp contg. 0.22% ash and 78.75%  $\alpha$ -cellulose. Pulp of satisfactory quality for rayon manuf. was obtained by first freeing the air-dried bagasse as far as possible from pith by rubbing and sieving and then treating the material to a preliminary process of fractional digestion as follows: (a) Boil with water with continuous agitation, then filter through a coarse sieve; repeat the operation; this removes starches, sugars, sol. gums and other water-sol. matter, together with some more finely divided pith. (b) Boil with 1%  $\text{NaOH}$ ; the pith matter attached to the fibers swelled and could be fairly readily sepd. by agitation; repeat this operation and remove resins, fats, waxes, etc., together with pectose. (c) Wash further in water and finally free the material from almost the whole of the remainder of the pith by a light beating in the hollander. Cooking under the previously stated conditions yielded 68% of dry bleached pulp on the dry prep'd. material (approx. 26% on the dry original bagasse) which gave the following results on analysis:  $\text{H}_2\text{O}$  7.7, ash 0.14,  $\alpha$ -cellulose 86.1,  $\beta$ -cellulose 12.6,  $\gamma$ -cellulose 1.3%, Cu no. (by Braid's method) 0.56, phloroglucinol absorption 1.19%, soda absorption value 215,  $\text{Me}_2\text{CO}$  ext. 0.26%. Bleached sulfite pulp prep'd. in Australia from Tasmanian stringy-bark had the following compn. on the dry basis: ash 0.32%,  $\alpha$ -cellulose 88.6,  $\text{Me}_2\text{CO}$  ext. 0.44%, Cu no. (by Braid's method) 1.9, which indicates it would be suitable for rayon manuf. *Phormium tenax* fiber from New Zealand cooked under the previously stated conditions gave a 70.5% yield of dry bleached pulp (on dry fiber) which gave: ash 0.09,  $\alpha$ -cellulose 89.8,  $\beta$ -cellulose 7.0,  $\gamma$ -cellulose 3.1,  $\text{Me}_2\text{CO}$  ext. 0.12%, Cu no. 0.824. The compn. of the pulp compares very favorably with that of bleached sulfite wood pulp commonly used for rayon manuf.; but it seems doubtful whether it could compete with wood pulp, because of the value of *Phormium* tow for other purposes.

A. PAPINEAU-COUTURE

**Determination of the viscosity of pulp for rayon manufacture.** ERIK ÖMAN. *Tech. Hochschule, Stockholm. Papier-Fabr.* 26, 770-8(1928).—Pulp for this purpose is tested by prepg. viscose experimentally and detg. its viscosity. The viscosity of any sol depends upon the degree of dispersion of the colloidal particles which it contains. Hence the prepn. of the viscose for testing must be carried out in a standard manner such that all factors, other than the nature of the pulp tested, which might influence the degree of dispersion of the cellulose, are avoided or maintained const. Otherwise concordant results cannot be obtained. After careful tests the following method has been adopted, and is recommended: The sample of (sheet) pulp is cut in 0.5 cm. squares. An air-dry sample equal to 0.900 g. oven-dry is treated with 10–20 cc. of 18%  $\text{NaOH}$  in a 25-cc. weighing bottle, and allowed to stand 2 hrs. in a thermostat at  $20^\circ$ . It is then sucked as dry as possible on a glass filter and pressed between linen cloths backed with filter paper, with a total pressure of 2000 kg. The cake is broken up and spread on the bottom of a 350-cc. bottle, in which is put an evapg. dish contg.  $\text{CS}_2$ . Bottle and dish should sit perfectly level, and the amt. of  $\text{CS}_2$  present should be such that some remains unevapd. after the treatment. The stoppered bottle with its contents are kept at  $20^\circ$  for 6 hrs., when the dish is removed and 100 cc. of 4%  $\text{NaOH}$  soln. contg. 0.40 cc. of  $\text{CS}_2$  is added

to the pulp. After standing for 17 hrs. the bottle is strongly shaken and allowed to stand 28 hrs. more. This latter time can probably be much reduced. The viscosity is detd. at  $20^\circ = 0.05$ , in an Ostwald pressure viscometer of the influx type; the use of an efflux viscometer may introduce a large mech. error due to adherence in the upper capillary and bulb. It was found experimentally that drying the pulp at  $130^\circ$  decreases the viscosity, while soaking increases it. Rapid cutting in the beater gives a considerable increase in viscosity. The pressing is important; if 7 g. of mercerizing soln. were left in the pulp the viscosity obtained was 6, whereas if all but 2 g. were pressed out the viscosity rose to 12. It is also necessary that the soln. be evenly distributed through the pulp. This effect of NaOH is ascribed to a rather mech. protective action on the fibers. Treatment with  $\text{CS}_2$  gas gives more uniform results than the use of liquid. If the bottle used is too large or the amt. of  $\text{CS}_2$  too small, low values are obtained. The directions given should be followed closely.

R. H. DOUGHTY

Proposed method for the quantitative determination of pitch in wood pulp. ROGER C. GRIFFIN. Arthur D. Little, Inc. *Paper Trade J.* 88, No. 9, 45; *Paper Mill* 52, No. 8, 38(1929).—A detailed description of the method which is being worked upon with a view to developing an official method to be adopted by the Tech. Assoc. of the Pulp and Paper Industry.

A. PAPINEAU-COUTURE

The Keebra process. LINN BRADLEY AND EDWARD P. MCKEEFFE. Bradley-McKeeffe Corp., New York. *Paper Trade J.* 88, No. 8, 131-3(1929).—A brief general discussion of the process (in which wood is pulped with a liquor contg.  $\text{Na}_2\text{SO}_3$  as the main chem. constituent) and its various modifications (addn. of one or more of the following chemicals:  $\text{NaHSO}_3$ ,  $\text{Na}_2\text{S}$ ,  $\text{NaOH}$ ,  $\text{Na}_2\text{S}_2\text{O}_8$ ,  $\text{Na}_2\text{CO}_3$ ,  $\text{NaHCO}_3$ ,  $\text{Na}_2\text{SO}_4$ ,  $\text{NaCl}$ ).

A. PAPINEAU-COUTURE

Observations on spruce "bull wood" and on sulfate and sulfite pulp made therefrom. S. ULFSPARRE. *Svensk Pappers-Tid.* 31, 642-4(1928).—"Bull wood" differs from ordinary wood in having a darker and brownish color and in being harder. The annual rings are relatively wide with light colored spring growth and reddish summer growth. Sp. gr. is 0.72. Analysis shows that spruce bull wood has a higher lignin content than ordinary spruce wood with consequent greater soly. in alkali and a lower resin content; it contains 52.30% C and 6.01% H against 50.05% C and 6.08% H for ordinary spruce. The cellulose content of bull wood is only 41%. In the sulfate pulping trials 155 g. of chips contg. 6-8% moisture were put in a rotating, electrically heated, Fe autoclave of about 1 l. capacity. To this was added 775 cc. of liquor contg. 175 cc. of NaOH soln. equiv. to 84.6 g.  $\text{Na}_2\text{O}$  per l.,  $\text{Na}_2\text{CO}_3$  2 g. per l.,  $\text{Na}_2\text{S}$  33.0 g. per l. and 600 cc. distd. water. The NaOH was purified by alc., and the  $\text{Na}_2\text{S}$  was c. p. as com. white liquor attacked the digester and gave a colored pulp. The digesting was continued for 30 mins. at  $20-100^\circ$ , 90 mins. at  $100-170^\circ$ , and 105 mins. at  $170^\circ$ . The digester was given half a turn every 7.5 mins. The resulting pulp was washed free from alkali and then dried. The quality of the yield from the bull wood was poorer than that from the ordinary spruce or pine wood. The sulfite test was conducted partly in a rotating electrically heated steel digester of 55 l. capacity, and partly in a Pb-lined 1 l. autoclave similar to that used in the sulfate digestion. Other treatment was about the same as in the sulfate process. The steel digester yielded bull wood pulp of darker color, of poorer yield, of less strength and of greater ash content than pulp from ordinary spruce wood. The pulp from the Pb-lined autoclave showed similar results. Tables give detailed numerical data. Pulp made from wood contg. 10% bull wood had a characteristic grayish brown color.

W. SEGERBLOM

Utilization of wood waste and "waste" woods through the semi-chemical pulping process. C. E. CURRAN. Forest Products Lab., Madison, Wis. *Paper Trade J.* 88, No. 5, 66-8(1929).—Expts. are described in the application of the semi-chem. process (impregnating the chips under pressure with a soln. of  $\text{Na}_2\text{SO}_3$  and  $\text{NaHCO}_3$ , removing the excess liquor, and cooking only with the reagents absorbed, the softened chips being then reduced to pulp by appropriate refining). Semi-chem. pulps from these sources are suitable for incorporation in various types of paper boards, including insulating boards, replacing more expensive pulps and thus offering an outlet for raw materials that at present are largely economic wastes.

A. PAPINEAU-COUTURE

Determination of the chlorine consumption number (of pulp). M. KLEINSTUCK. *Wochbl. Papierfabr.* 59, 666-9(1928).—Directions for the prepn. of a standard NaOCl soln. for this purpose are given.

R. H. DOUGHTY

Physical standards for pulp. H. A. ROTHCHILD. Kimberly-Clark Corp. *Paper Mill* 52, No. 8, 118, 120(1929); *Paper Trade J.* 88, No. 11, 52-3(1929).—The large variety of testing methods and varied preferences of different operators make the general adoption of a definite standard method almost impossible. It is therefore suggested

that pulps be evaluated by comparing with a standard sample which is subjected to the same testing procedure as the pulps which are to be evaluated. A. P.-C.

The proposed standard method of pulp evaluation. H. AINSWORTH HARRISON. *World's Paper Trade Rev.* 91, 1016, 1022-6, 1194-1206, 1282-96(1929); *Paper Maker & Brit. Paper Trade J.* 77, 368-74(1929).—A description of the method for detg. the initial, or unbeaten, strength of pulp proposed for adoption as international standard by the Technical Section of the Paper Makers' Assoc. of Gt. Britain, followed by a discussion by the members present at the meeting. A. PAPINEAU-COUTURE

Factors in the sizing of paper pulp. RENÉ ESCOURROU. *Chimie et industrie* 20, 1039-42(1928).—A brief discussion of the effects of the chief factors involved in sizing: water,  $p_H$  value, rosin, stock and impurities. A. PAPINEAU-COUTURE

Further research and experiment in pulp drying. R. D. KEOH. *Pulp Paper Mag. Can.* 27, 273-6(1929).—A discussion of the merits of the Fidalgo Drying System, which consists in sheeting the pulp on a Kamyrt wet machine, shredding the moist sheet, drying the shredded pulp and baling it for shipment. A. PAPINEAU-COUTURE

A semi-automatic sheet machine for pulp strength testing. HELLM. SCHWALBE. *Paper Trade J.* 88, No. 5, 63-5(1929).—In order to obtain the thorough mixing required for the production of a uniform and satisfactory test sheet, a stirring chamber is mounted directly over the wire on which the sheet is formed and is provided with an electrically driven agitator. In order to transfer the stock from the round stirring chamber on to the rectangular wire, the 2 are connected by a suitably shaped connecting chamber inside which are vanes which in the upper part are parallel to the short side of the wire and in the lower part are parallel to the long side. While the pulp is being stirred in the stirring chamber, the connecting chamber is filled with water; and when stirring is completed (5 mins.), the slide between the mixing chamber and connecting chamber and the drain valve are opened simultaneously. At the end of 5 mins. the underframe of the sheet machine is lowered, the sheet mold is taken out and the sheet is couched off with only the wt. of the sheet mold, no hand pressure being applied. Results of tests made on sheets prepd. with this machine are given, showing that the sheets are much more uniform than with other sheet machines, the deviation of individual tests from the mean very seldom exceeding 5%. A. PAPINEAU-COUTURE

Testing the strength of pulp. GOSTA HALL. *Svensk Pappers-Tid.* 32, 151-8(1929).—A résumé of methods used in America and a report on standardizing the methods used in Sweden. WILHELM SEGERBLOM

Strength testing of chemical pulp. Comparison of beating tests with the Abbé pebble mill and a new metal ball mill. GOSTA HALL, Korsnas Wood Pulp Mills, Gefle, Sweden; AND WILLIAM S. WOODSON, JR., Albemarle Paper Mfg. Co., Richmond, Va. *Paper Trade J.* 88, No. 4, 51-5(1929).—Results are given of comparative beating tests on strong unbleached sulfate and bleached sulfite pulps with the Abbé pebble mill and the new Abbé metal ball mill. In order to be able to replace the pebble mill directly with the ball mill without requiring any change in the drive of the app., the new mill was adjusted to 60 r. p. m.; but this speed proved unfavorably slow, because in order to get a sufficiently quick beating action it was necessary to use very large metal balls (25 1-in. and 10 1.25-in. balls) which caused excessive shortening of the fibers in the beating. The temp.,  $p_H$  and freeness of the stock were detd. at the beginning and end of each run, and the test sheets were tested with the Gurley densimeter, Schopper folding and tensile strength testers and Elmendorf tearing tester. The action in the pebble mill is characterized as primarily a tearing-up of the fibers, while that of the ball mill is a crushing and shortening of the fibers. Ball-mill beating therefore gives a paper of higher d. than pebble-mill beating, although higher degrees of beating (as measured in the Williams freeness tester) are reached with the pebble mill at all beating intervals; the same pulp beaten in the ball mill gives constantly a paper of higher d. With continued beating the ball-mill beaten pulp is throughout superior to the pebble-mill beaten pulp as regards both bursting strength and breaking length, in the case of both sulfate and sulfite pulps, showing that the d. follows the changes in strength more closely than the degree of beating. The tensile and bursting strength curves accompany each other closely, and these 2 strength properties can be considered parallel functions of the beaten conditions; and it is shown that if a paper of high bursting and tensile strength is wanted the beating should aim at a combination of crushing and moderate shortening of the fibers, the small fiber fragments which form an unavoidable by-product in any beating probably contributing to a high tensile and bursting strength by closing the paper structure and cementing the fibers together. The losses of fiber fragments on the sheet mold often affect the max. in bursting and tensile strength which the beating curves show, so that it is necessary to standardize both the fineness of the wire cloth and the suction

applied in order to get concordant results. The folding-strength curves of the sulfate pulp show that pebble-mill beating gives a more pliable paper than ball-mill beating; but the bleached sulfite did not show the same results because, due to the rubbing between the pebbles, the fibers are curled and kneaded together into lumps and knots which lower the strength. Judging from the tearing-strength curves the heavy balls of the bronze mill caused a pronounced shortening of the fibers; but this was not revealed in the photomicrographs. No final conclusions as to beating action of the metal ball mill can be drawn from these preliminary tests, because too large balls were used. Further expts. in Sweden have shown that excessive shortening of the fiber can be avoided and the beating action modified by using smaller balls (e. g.,  $\frac{3}{8}$  in. diam.) and running at higher speeds. The increase in ash was 0.1% in the ball mill and 0.4% in the pebble mill, which could have no influence on the results of the strength tests. An av. of 7° F. rise in temp. was measured in a 4-hr. ball-mill run with sulfate pulp as against 5° F. in the corresponding pebble-mill run. The  $p_H$  value changed from 7.6 to 7.8 in the pebble mill and from 7.6 to 8.0 in the ball mill during the same 4-hr. run with unbleached sulfate, the difference being attributed to more thorough "squeezing" of the fibers in the ball mill, whereby a larger portion of the alkali absorbed by the pulp is brought into soln. From a general comparison between the variations of individual strength properties, the bursting strength appears to be the most consistent exponent of the strength, the bursting test giving the most concordant results, while the folding endurance shows the largest deviations between duplicate detns.

A. P.-C.

**Utilizing groundwood rejections.** W. E. BROWN. Pejepscot Paper Co., Brunswick, Me. *Paper Mill* 52, No. 8, 142-6; *Paper Trade J.* 88, No. 11, 63-4; *Pulp Paper Mag. Can.* 27, 353-5(1929).—A brief discussion pointing out certain paths of investigation for elimination and greater utilization of groundwood rejections. Tailings utilization eliminates a source of stream pollution, conserves raw materials and tends to extra profits for the mill. The first step in the utilization of tailings is to study the mill operation in detail and keep all forms of rejections down to a min. Studies should be made into more efficient methods of handling rejections, both for use in the mill and for shipment to distant points. Further investigation is necessary to find addnl. uses to which tailings may be put. Various types of groundwood tailings refiners are available, and these are briefly described.

A. PAPINEAU-COUTURE

**Invisible shrinkage (in pulp and paper mills).** A. W. PESCH. Falls Mfg. Co. *Paper Mill* 52, No. 8, 42, 158, 168; *Paper Trade J.* 88, No. 12, 61-2(1929).—"Shrinkage" (or more accurately "waste") through loss of fiber in white water should be detd. directly as accurately as possible, and not merely estd. by assuming a certain yield of pulp per "cord" or per cook and considering that the difference between the fiber production estd. in this manner and the amt. of fiber in the finished paper is lost in the white water. Any appreciable difference between the estd. and directly detd. white water loss should be carefully investigated to ascertain the cause of the discrepancy. The estd. loss is frequently much too high because the assumed yields are too high.

A. PAPINEAU-COUTURE

**Measurement of white-water flow with V-notch weirs and white-water analysis.** H. L. JOACHIM. Container Corp. of America, Philadelphia, Pa. *Paper Trade J.* 88, No. 1, 61-3(1929).—A brief discussion of the construction and use of V-notch weirs for measuring white-water flow in pulp and paper mills, and of the methods and value of white-water analysis, the detns. of greatest value to paper mills being total solids, total suspended material, total sol. material, sol. org. material, sol. mineral material, suspended org. material and suspended mineral material.

A. PAPINEAU-COUTURE

**Slime control (in pulp and paper mills) with chlorine and compounds of chlorine.** C. M. BAKER. Am. Paper and Pulp Assoc., Madison, Wis. *Paper Trade J.* 88, No. 2, 50-2(1929).—Concrete examples are given of the manner in which slime troubles were eliminated in 12 mills mfg. various grades of paper and board by judicious use of Cl. A review is given of the literature dealing with slime in pulp and paper mills. Conclusion: Chlorination is practical, effective and apparently inexpensive for a given operation, but owing to differences in the conditions in different mills, each mill is a sep. problem and should be studied individually.

A. PAPINEAU-COUTURE

**Artificial plastics in pulp and paper.** CHARLES W. RYVISE. *Paper Mill* 52, No. 8, 148-52; *Paper Trade J.* 88, No. 12, 62-4(1929); *Plastics* 5, No. 5, 261-2, 269-71(1929).—A brief review of the uses of artificial plastics in the paper industry, particularly for sizing.

A. PAPINEAU-COUTURE

**Research in pulp and paper work.** B. A. MELBY. *Paper Industry* 10, 1940-3(1929).—Report of the research committee of the Technical Society of the Norwegian Paper industry, describing the work done during 1923-28.

**Pulp and paper research in Canada.** E. P. CAMERON. Forest Products Labs. of Canada, Montreal. *World's Paper Trade Rev.* 91, 582-8(1929). A. P.-C.

**Sulfite pulp manufacture from sawmill waste.** ANON. *Wochbl. Papierfabr.* 59, 1395-6(1928).—Experience showed that such wood (slabs and edgings) was entirely unsuited for the manuf. of high-grade pulp, even though it was sorted by hand to remove all bark. R. H. DOUGHTY

**Bleaching sulfite pulp.** L. Rys. Eichmann & Co., Sandhübel, Schliesen, Czechoslovakia. *Paper Trade J.* 88, No. 1, 65-72(1929).—See C. A. 22, 3526. A. P.-C.

**Alkali-soluble components of sulfite pulp and artificial silk.** W. WELTZIEN. *Russä* 4, 367-73(1929).—See C. A. 22, 4802. A. PAPINEAU-COUTURE

**Washing and treatment of sulfite pulp.** ERIK ÖMAN. *Papier-Fabr.* 26, Fest-u. Auslands-Heft, 92-6(1928).—The pH of water used for washing was controlled between 5.3 (the normal value) and 8.1, by the continuous addn. of milk of lime soln. of 2° Bé., in a series of mill-scale expts. A pulp which had been given an alk. wash gave a better sized paper, and one which was somewhat softer and better in color than that washed on the acid side. The latter was, however, much more suitable for conversion to grease-proof paper. R. H. DOUGHTY

**The distribution of steam and warm water in sulfate pulp plants.** JONAS BOJJA. *Svensk Pappers-Tid.* 32, 49-52(1929).—Four uses for warm water and 9 sources of warm water in sulfate pulp plants are enumerated. The calcn. of the distribution of heat in these sources and uses is described. Similar data are given for the steam requirements. W. SÖGERBLÖM

**Chemistry of sulfite pulping. X. Determination of the degree of pulping.** ERIK HÄGGLUND. *Papier-Fabr.* 26, Fest-u. Auslands-Heft, 88-92(1928); cf. C. A. 23, 701 and following abstr.—The true measure of the degree of pulping (conversion) of an unbleachable sulfite pulp is the lignin content. It is shown that when the Sieber or Enso Cl no., or the Tingle Br. no. of several pulps are plotted against the lignin content, a straight line relation is obtained, over the range 2-7% lignin. The Roschier KMnO<sub>4</sub> no. gives a linear relation between 4 and 7% lignin, while the Björkmann KMnO<sub>4</sub> no. gives a curved line relation through the range studied. This behavior indicates that the ease with which a lignin is oxidized depends upon the degree of sulfonation, and also that the reaction of bleaching with hypochlorites is more than a simple oxidation effect. Under const. pulping conditions there is a definite relation between strength and lignin content of pulps. In those studied, a pronounced strength max. was found at about 5% lignin content. R. H. DOUGHTY

**Studies on the chemistry of sulfite pulping.** ERIK HÄGGLUND. *Papier-Fabr.* 27, 49-54(1929); cf. preceding abstr.—An address, reviewing and summarizing the published work of H. and his associates on this subject. R. H. DOUGHTY

**(Sulfite) pulping with hot water as a heating agent.** LEO FRIEDLÄNDER. *Papier-Fabr.* 26, 789-91(1928).—Indirect heating with H<sub>2</sub>O at 6-8 atm. under forced circulation is compared with direct and indirect heating with steam. The use of water should give the advantages of both the Mitscherlich and quick-cook sulfite processes, while avoiding many of their disadvantages. R. H. DOUGHTY

**Straw and the monosulfite process.** RAYMOND FOURNIER. *Papeterie* 51, 14-8 (1929).—A brief description and discussion of the Braun process (cooking with Na<sub>2</sub>SO<sub>3</sub>, NaOH and Na salts of weak acids such as Na borate or preferably silicate). F. considers that, although the process gives a fine pulp, it is questionable whether it is any more economical than, or possesses other advantages over, the de Vains and other halogen processes. A. PAPINEAU-COUTURE

**Paper pulp and cellulose from the eucalypts by the sulfite process.** L. R. BENJAMIN AND J. L. SOMERVILLE. *Australia Council Sci. and Ind. Res. Bull.* No. 37, 5-67 (1928); cf. C. A. 22, 3776.—The production of pulp from several species of *Eucalyptus* suitable for newsprint was studied on a lab. scale. The best pulp was produced by cooking for 5½-6 hrs. at 140° with liquor contg. 1.6% of combined and 3% of free SO<sub>2</sub>, using 1000 Imperial gallons of liquor per 2000 lbs. of oven-dry chips. *E. regnans* and *obliqua* were most satisfactory for yield and strength of newsprint. The latter, properly cooked, yields a pulp, when bleached, of 88.6% α-cellulose and 0.24% ash content suitable for viscose. *E. delegantensis* (gum top) was less satisfactory for newsprint but suitable for other purposes. The shorter cooking period compared with spruce, fir, etc., is attributed to the lower lignin contents of the eucalyptus and to the greater accessibility of the lignin to the liquor since the ultimate cells are shorter, finer and thinner-walled. Details of tests with *Pinus insignis* and *Acacia dealbata* (silver wattle) and photomicrographs of the various pulped fibers are given. F. A. SIMMONDS

**Sulfite digester operation.** F. HAYWARD JOHNSON, JR. Cherry River Paper Co.

*Paper Mill* 52, No. 8, 170-4(1929); *Paper Trade J.* 88, No. 11, 57-9(1929).—A discussion of the cooking schedule followed at the Richwood mill of the Cherry River Paper Co., explaining the reasons of the various steps. A. PAPINEAU-COUTURE

Conical covers of digesters. F. VON ZEIPPEL. *Svensk Pappers-Tid.* 31, 820-2 (1928); cf. *C. A.* 20, 3813; 22, 1849, 2083, 4809, 4810.—Four diagrams and 9 formulas are given for conical covers. W. SEGERBLOM

Sixty years' operating advancement in the sulfite industry. T. L. DUNBAR. Canadian Stebbins Engineering and Manufacturing Co. *Pulp Paper Mag. Can.* 27, 317-9(1929); *Paper Trade J.* 88, No. 9, 46-8(1929).—A brief outline of the progress and development of the sulfite pulp industry since its inception by Tilghman, with a short discussion of 3 recent improvements in sulfite equipment: digester fillers, liquor circulating systems and hot liquor and gas recovery. A. PAPINEAU-COUTURE

The chemical reactions during pulping by the alkali method. H. E. WAHLBERG. *Svensk Pappers-Tid.* 32, 44-9(1929).—A résumé of the equations which have been proposed by various investigators to show the reactions involving cellulose, lignin and hemicellulose in the alkali pulping process. Several graphs and illustrations of mol. structure accompany the article. W. SEGERBLOM

Control of the progress of the cooking processes in the pulping industries. ERIK HÄGGLUND. *Svensk Pappers-Tid.* 32, 84-8(1929).—The properties of both the cooking liquor and of the pulp must be controlled. Various methods in general use for the taking of samples and for their examn. are described briefly. Conclusion: The Bjorkman modification of the Roschier method gives the best results. W. SEGERBLOM

The dependence of hardness of sizing on the degree of beating. JOHANNES BERGER. *Paper Maker & Brit. Paper Trade J.* 76, Annual No. 59-61(1928).—The hardness of sizing of a no. of papers of different degrees of beating was compared with a no. of groundwood-free printing papers of different degrees of sizing. The floating method was used in every case to det. the degree of sizing, and each sample was subjected to 4 tests, using, resp., (1) 0.1% NaOH and dry phenolphthalein indicator, (2) 1%  $\text{NH}_4\text{CNS}$  and  $\text{FeCl}_3$  indicator, (3) tannic acid soln. with powd.  $\text{FeCl}_3$  indicator and (4) a soln. of ink. The quarter- and half-sized papers are surpassed in hardness of sizing by papers of a lower degree of beating. Resistance to penetration by ink increases with increase in beating, especially between the degrees of beating of 50-70 (Schopper-Riegler), where the slump character of the mucilage begins to be manifested. As the degree of beating increases from 10 to 94, the capacity for resisting penetration by the testing liquid increases approx. 365, 98, 90 and 10,000 times, resp., by the different methods used; while the completely sized printing paper was 27, 33, 18 and 1500 times more resistant than the unsized paper, when tested by the 4 methods, resp. The method using NaOH initially gives more favorable results than with ink, but with a more lengthy contact with the testing liquid the values become inferior, because of the detrimental action of the NaOH on the sizing of the paper, the alkali apparently having a solvent action on both rosin and cellulose-mucilage sizing. Methods (2) and (3) differ considerably in the results compared with the method using ink, and it is considered that the use of either ink or NaOH with phenolphthalein as indicator affords the best means of gaining an insight into the extent of sizing. A. PAPINEAU-COUTURE

Pulping of annual grasses, etc., by the chlorine process. J. L. SOMERVILLE AND L. R. BENJAMIN. *J. Council Sci. Ind. Research* 1, 217-26(1928).—A comparison is made of the soda, de Vains and Cataldi processes as applied to the pulping of annual grasses. In the de Vains process the best cooking and chlorination conditions were: NaOH equiv. as a % of the oven-dry pulp, 0.192; initial concn. of  $\text{Cl}_2$ , 5 g. p. l.; consistence of pulp during chlorination, 4.1; cooking time, 2.5 hrs.; yield of bleached pulp, 51.4% of oven-dry cane; cellulose content, 73.3%; Cu. no. 0.67. The alk. treatment of the chlorinated pulp consisted of washing and heating with about 0.06 g.-equiv. of NaOH or  $\text{Na}_2\text{CO}_3$ . The consumption of alkali was nearly 0.03 g.-equiv. of NaOH per 100 g. of oven-dry cane. The use of black liquor for this alk. treatment resulted in an increase of 50% in the  $\text{Cl}_2$  consumption during the bleaching. The pulp thus produced is very white, contains 71%  $\alpha$ -cellulose, and a very low Cu. no. The paper made from the unbeaten pulp has properties of rattle, hardness, translucency, lack of absorbency, close texture and a bursting strength of 82 points per lb. per ream due to great fiber length. Screening the pulp on a 60-in. sieve reduced the yield but gave a softer and more pliable paper. Bond paper made from the pulp had a bursting strength of 110 points per pound per ream ( $25 \times 40-500$ ), excellent color, good formation, but is hard and insufficiently pliable. In view of these tests the authors are doubtful that de Vains straw pulp will be extensively used in newsprint. F. A. SIMMONDS

Relation of pulp-stone grit to quality of fiber. LANGDON S. SIMMONS AND BERNARD

**BORNSTEIN.** The Norton Co., Worcester, Mass. *Paper Mill* 52, No. 8, 100-4; *Paper Trade J.* 88, No. 10, 50-2(1929).—A discussion of the influence of the size of grit of natural sandstone and of Norton artificial pulp stones together with the type of burring on the quality of the fibers produced. **A. PAPINEAU-COUTURE**

**Pulp-stone grit in mechanical pulp.** EDWIN A. RILEY. Pejepscot Paper Co., Brunswick, Me. *Paper Trade J.* 88, No. 8, 171(1929).—A brief discussion of the degree of contamination of groundwood by grit from the stones, and of its elimination from pulp required for semi-fine papers. **A. PAPINEAU-COUTURE**

**Mill research.** VANCE P. EDWARDS. Northwestern Pulp & Paper Co., Astoria, Ore. *Pulp Paper Mag. Can.* 27, 69-70(1929).—The possibilities of mill research are strikingly exemplified by listing the results actually accomplished in a particular sulfite mill by keeping a continuous record of operating conditions and carefully studying the results. The strength of the finished pulp was shown to vary as the  $H_2O$  content of the chips, which varied according to the relative soundness of the wood, the older wood being the drier. Increasing chip length of both hemlock and spruce from  $\frac{1}{2}$  to 1 in. reduced sawdust loss and correspondingly increased digester yield, the approx. saving being \$0.23 a ton.  $SO_2$  consumption varied inversely as the  $SO_2$  concn. of the burner gases. By studying the relationship between the degree of pulping (as measured in the lab.) and yield, cost and bleachability of the pulp, standard cooking conditions were worked out which reduced the cost of pulp \$1.85 per ton and increased the mill output over 1 ton per day. Adoption of arbitrary standards of pulp quality in connection with digester control brought the pulp rating from an av. of 70% to 95% in less than 1 yr., and digester steam consumption was reduced about 40%, reducing steam cost per ton and increasing the boiler plant efficiency. **A. PAPINEAU-COUTURE**

**Alternating current motors in the paper industry.** ERNST BLAU. *Papier-Fabr.* 26, 791-3(1928).—General. **R. H. DOUGHTY**

**Air in steam, and a new apparatus for removing air from drier cylinders.** v. LASSBERG. *Papier-Fabr.* 27, 33-9(1929).—Data are given illustrating the fact that boiler water may contain considerable dissolved gas, and that the accumulation of this gas in the driers is detrimental to proper operation. A new app. (Lütschen-Entlüfter) for venting steam lines and driers is described. **R. H. DOUGHTY**

**Removal of condensate from rapidly revolving drying cylinders by means of centrifugal force.** E. ÖMAN, N. SUNDSTEDT AND E. ÖSTNÄS. Royal Technical High School, Stockholm. *Svensk Pappers-Tid.* 31, 710-2, 746-8(1928).—The interior of the drying cylinder is supplied with longitudinal grooves sloping toward a circular chamber on the outlet side, from which the condensate is removed through the trunnion by means of a scoop. The theory of action is shown by several diagrams. Approx. the same temp. of the drying cylinder's surface resulted whether the water was removed as rapidly as possible or whether the inner surface of the cylinder was covered with a film of water. **W. SEGERBLOM**

**Recent developments in the use of chain-grate stokers.** PRADEL. *Papier-Fabr.* 27, 8-13(1929).—P. considers this type of boiler firing as superior to the use of powd. coal. Notes on proper plant construction and operation are given. **R. H. DOUGHTY**

**Multi-motor drive for a fine-paper machine.** HEINRICH KUHN. *Papier-Fabr.* 27, 17-22(1929).—A general discussion. Curves are given showing the relations between speed and voltage, paper weight and power consumption, also the power consumption of the sep. parts for several weights of paper, as detd. on a typical machine. **R. H. D.**

**Bibliography of paper making for 1928.** CLARENCE J. WEST. Natl. Research Council, Washington, D. C. *Paper Trade J.* 88, No. 8, 173-231(1929). **A. P.-C.**

**The importance of aluminum sulfate in paper manufacture.** HELM. ROSCHNER. *Papier-Fabr.* 26, 757-61(1928).—See C. A. 22, 3776. **R. H. DOUGHTY**

**Bamboo (for papermaking).** W. RAITT. *Proc. Tech. Sect. Papermakers' Assoc.* 8, 89-98(1927).—Claims that bamboo is a practically inexhaustible source of paper pulp are advanced. The earlier difficulties of prepg. bleached bamboo pulp have been overcome and the waste due to nodes has been eliminated by crushing. By adopting fractional digestion in conjunction with the sulfate-soda process it is possible using 16% of soda for 5 hrs. at 24 lbs. per sq. in. to obtain a 45% yield of pulp requiring only 8% of bleaching powder (yield of bleached pulp 42%). It is estd. that unbleached bamboo pulp could be delivered at British ports for about \$56 per ton. **F. A. SIMMONDS**

**Colloids in paper making.** J. CHARVET. *Papeterie de Rives. Papier* 32, 41-52(1929).—A brief discussion of the properties of colloids used in paper making, particularly gelatin and also fillers. **A. PAPINEAU-COUTURE**

**Pine wood for paper making.** J. A. FOURMYER. *Bull. Inst. pin.* No. 57, 82-4(Feb.,

1929).—A brief discussion of the advantages of the production of groundwood and newsprint in the Landes from maritime pine.

A. PAPINEAU-COUTURE

(The paper-making qualities of) *Pinus hamiltoni* (Corte's Pino maritimo). IGNACIO ECHEVERRIA and SIMÉON DE PEDRO. *Bull. inst. pin.* No. 57, 55-7 (Feb., 1929).—This is a variety of *P. maritimus*. The av. of 4 analyses gave:  $H_2O$  59.60,  $EtOH-Et_2O$  ext. 0.688 (1.699 on dry basis), cellulose 21.55 (53.36% on dry basis). Cooking 2 kg. of wood for 14 hrs. at a pressure of 4 kg. per sq. cm. with 400 g. NaOH and 200 g.  $Na_2S$  in 8 l. of water gave a 23% yield of hard pulp, which was difficult to bleach. The fiber length was 3 mm. and diam. 0.045 mm.

A. PAPINEAU-COUTURE

Paper-making qualities of mangrove wood. L. VIDAL and M. ARIBERT. *École Française de Papeterie, Grenoble. Agronomie Coloniale* 17, 203 (1928); *Bull. Imp. Inst.* 26, 493 (1928).—Three species of mangrove from Madagascar were studied, the pulping tests being carried out with 25% NaOH (on the wt. of the wood) at a concn. of 18° Bé. for 8 hrs. under a pressure of 5 kg. *Rhizophora mucronata* ("Honkolahy") had a d. of 0.94, cellulose 48.2% and  $EtOH-Et_2O$  ext. of 4.5%, and gave 47% of pulp which was very difficult to bleach (yielding 42% of bleached pulp). *Bruguiera gymnorhiza* ("Tsilolona") had a d. of 0.95, cellulose 46.0% and  $EtOH-Et_2O$  ext. 2.9%, and yielded 46% of pulp which was extremely difficult to bleach (yielding 39% of bleached pulp). *Ceriops boiviniana* ("Honkovavy") had a d. of 1.03, cellulose 45.0% and  $EtOH-Et_2O$  ext. 4.9%, and yielded 47.5% of pulp which was even more difficult to bleach than the preceding ones. Satisfactory pulping of these woods would demand such severe treatment that the cost would be prohibitive, and the papers which they furnish are very weak. The manu. of bleached pulp would be impracticable; but it might be possible to produce a coarse unbleached pulp suitable for wrapping paper.

A. PAPINEAU-COUTURE

Improvements in coated paper manufacture. FRANK W. EGAN. John Waldron Corp. New Brunswick, N. J. *Paper Mill* 52, No. 8, 128-34; *Paper Trade J.* 88, No. 10, 53-6 (1929).—A brief outline of the improvements which have been made in paper coating method and equipment during the last 30 yrs or so.

A. PAPINEAU-COUTURE

Mill water supplies and waste (in the paper industry). C. M. BAKER. American Paper and Pulp Assoc. *Paper Mill* 52, No. 8, 40, 44, 176, 178; *Paper Trade J.* 88, No. 12, 64-6 (1929).—From a discussion of the relation between white water utilization and quality and quantity of the mill water supply, B. concludes: (1) The recirculation and utilization of white water directly affects water supply developments and purification in that it materially reduces the amt. of fresh water required, thus resulting in a substantial saving in pumping costs, capital investment and the cost of treatment. (2) The first step in any water supply development or improvement should involve a careful study or survey in white water utilization in order to reduce the quantity of water necessary to a min. (3) Reduction in water consumption correspondingly reduces the vol. of wastes that it is necessary to discharge into water courses, thus improving stream conditions, and should this improvement be inadequate, the cost of treatment of the residual wastes would be proportionately less.

A. P.-C.

Stuff preparation. J. J. O'CONNOR. Mead Pulp and Paper Co. *Paper Mill* 52, No. 8, 108, 110 (1929).—A brief discussion of the importance of devising tests which will give a practical valuation of the raw material, as such and in the course of prepn., for any particular grade of paper.

A. PAPINEAU-COUTURE

The Delthirna sizing process. P. DELCROIX. Papeteries Navarre. *Papier* 32, 73-83 (1929); cf. *C. A.* 22, 1853.—An account of the results obtained in the actual application in mill operations of the process, which consists essentially in treating lump rosin with a dil. NaOH soln. (about 15 g. per l.) at not less than 15°. The equipment of the exptl., semi-com. unit at the French School of Paper Making, Grenoble, and of the com. unit at the Papeteries du Pont-de-Claix are described. The process gives automatically a size soln. of practically const. compn. without requiring any attention other than filling the rosin towers, and superior sizing is obtained with an approx. 20% lower rosin consumption.

A. PAPINEAU-COUTURE

Rosin sizing by the Delthirna process. E. ÖMAN. *Pulp Paper Mag. Can.* 27, 282, 304-6 (1929); *Svensk Pappers-Tid.* 31, 637-41 (1928).—A discussion of the results obtained in the application of the process (covered by Swedish patent 63,230), which possesses the following advantages: it is automatic and continuous; the soln. has a const. compn.; the app. does not require any attention other than to be charged with rosin once a day; the size soln. is highly concd. (40 g. per l.); troubles from clogged pipes, dirty floors, etc., are eliminated. The mechanism of rosin sizing is discussed to explain the superiority of the Delthirna process over the ordinary process.

A. P.-C.

The effect of heat on rosin sizing in the drying of the wet paper sheet. E. ÖMAN. *Svensk Pappers-Tid.* 31, 536-9, 570-2 (1928); cf. *C. A.* 23, 976.—Samples of pulp were

sized according to a standard procedure and the wet hand sheets were heated between two iron plates in a temp.-controlled oven for predetd. periods and then air-dried. The degree of sizing was detd. by the "ink streak" method. The effects of the following variables were detd.: temp., time of heating, moisture in the sheet and the hydrogen-ion concn. ( $p_H$ ) of the sized pulp. The critical temp. was found to be 73–75° and the critical moisture content about 50%. Higher values had a harmful effect on the degree of sizing unless the heating time was very short, less than one minute. With shorter heating time the sizing is better in all cases.  $p_H$  had no effect on sheets air-dried only, but  $p_H = 5.0$  was found to be best for sheets with 75% moisture heated to 85° for either 15 or 30 secs. Alk. conditions ( $p_H = 8.0$ ) gave extremely poor results.

W. SEGERBLOM

**Further experimental facts connected with rosin sizing.** S. R. H. EDGE. *Paper Makers' Monthly J.* 67, 50–3(1929); cf. *C. A.* 22, 1684.—When the  $p_H$  value was controlled by adding successive amts. of 5% alum soln. after adding the rosin, max. sizing was obtained at a  $p_H$  value of 5.0; when 75 cc. of alum soln. was added after the rosin, and the  $p_H$  value was then adjusted with 5% NaOH or 3%  $H_2SO_4$ , max. sizing was obtained at a  $p_H$  value of about 4.0. There is much more rapid falling off in the sizing with excess acid than with excess alum. In the lab. the easiest way to get the highest comparative sizing figures is to add the rosin, then bring the stock to a  $p_H$  of 5.0 with acid and then add alum 5 or 10 cc. at a time and make a series of sheets. Addn. of an excess of rosin over that required to obtain the full sizing effect acts like loading and reduces the sizing. With lab.-made sheets, 85 appears to be the max. possible comparative sizing figure; in mill-made paper, with rosin content up to 4% and different beating and calendering conditions, only 2 cases were discovered higher than 85 (93 and 86), which seems to indicate that this figure may have a real significance. For mill-made waterleaf rag papers, the max. appears to be 20, and the av. 10–5. Pulp as received, after treating with  $H_2SO_4$ , and after treating with alum, did not show any difference in comparative sizing. The theory of Thiriet and Delcroix (*C. A.* 20, 286, 2071) requires that other salts, which buffer a soln. at the  $p_H$  values from which alum readily gives sized sheets, should also be sizing agents, and also that the retention of rosin should be greater within the sizing range of  $p_H$  values. Using a mixt. of NaOAc and AcOH to buffer the soln. and adding AcOH slowly to vary the  $p_H$  value right through the usual sizing range failed to produce a single sized sheet; the rosin contents of the series of sheets made at different  $p_H$  values were invariably the same within the errors of detn., whether the sheets were sized or not. The theory thus fails completely. According to the literature, the range of  $p_H$  values produced by adding alkali to Th sulfate soln. is very close to that given by alum, the buffering action being slightly on the acid side of that given by alum. Sizing expts. with Th sulfate gave a max. comparative sizing of 42.5 (instead of 85 as with alum), and from 4 to 5 times as much Th sulfate as alum was required to give the max. Cr, Fe and Na sulfates were tried at various  $p_H$  values, but entirely without success. The results are considered to justify the conclusion that, under the conditions of the expts., there is a peculiar efficiency about alum as a sizing agent not possessed by any other metal, and not due to its buffer action alone, its valency alone, or its very weak basicity. It seems to be a property of the metal rather than of the salt, since the chloride dissolved in water or the acetate dissolved in AcOH is just as effective as the sulfate.

A. PAPINEAU-COUTURE

**The effect upon rosin sizing of heating the moist paper sheet.** ERIK ÖMAN. *Tech. Hochschule, Stockholm. Papier-Fabr.* 26, 705–7(1928).—See *C. A.* 23, 976.

R. H. DOUGHTY

**Proposed method for the analysis of rosin size (for paper making).** E. FRANK WHITTINGTON. Sutherland Paper Co., Kalamazoo, Mich. *Paper Trade J.* 88, No. 8, 231. *Paper Mill* 52, No. 8, 136(1929).—The method eliminates the necessity of using Pt ware for the alkali detn., and is based on the fact that the amt. of acid necessary to liberate the combined rosin is directly proportional to the amt. of alkali combined with the rosin. Det. total solids by heating to const. wt. at 230° F., weighing at the end of 30 mins. and then at 10-min. intervals. To det. free rosin, dissolve 2 g. in neutral alc. and titrate with 0.1 N alc. KOH, using phenolphthalein indicator. To det. total rosin, work up the residue from the total solids detn. into a paste with boiling water, and gradually add water to a total of about 100 cc., add 40 cc. 0.1 N  $H_2SO_4$ , ext. with  $Et_2O$  with the usual precautions as regards washing, etc., evap. the  $Et_2O$  and weigh the residue of rosin. To det. total alkali, titrate the excess  $H_2SO_4$  in the soln. and washings from which the total rosin was extd.

A. PAPINEAU-COUTURE

A new  
discussion of the merits

J. DUCHAILLUT. *Papier* 32, 95–103(1929).—A  
Schilde drying system, in which the sheets of board are

passed through a drying chamber or tunnel where they are supported flat on a suitable endless flat porous conveyor, instead of being hung up by clips. Heating coils extend throughout the whole length of the tunnel, both above and below the boards. The ventilation system is designed to ensure even and uniform impingement of air perpendicularly to the surface of the board, both from above and below, and the air is used repeatedly by reheating it to increase its drying power. **Corrosion in paper mills.** I. R. MCCALL. Detroit Graphite Co., Milwaukee, Wis. *Paper Trade J.* 88, No. 8, 157-67(1929).—A brief survey of the various points where corrosion can occur and of the means of preventing it, bringing out particularly the efficiency of properly selected and properly applied paint. A. PAPINEAU-COUTURE

**A natural system for the analysis and classification of paper.** A. S. HAMMOND. Western Waxed Paper Co., North Portland, Ore. *Paper Trade J.* 88, No. 7, 55-8(1929).—The system proposed consists in detg. the "bulk index" (the caliper of the paper for a given base wt.), the porosity (by measuring the amt. of paraffin oil which the paper will absorb) and the apparent d. of the fiber substance (obtained by dividing the wt. of the paper by the vol. of the fibers, which is found by subtracting the vol. of the voids from the vol. of the paper). It is based on the following laws: (1) In the gelatinization (which is taken to include all "hydration" effects produced by mech. and (or) chem. reactions) of paper fibers the percentage of apparent voids in the sheet progressively decreases, and this decrease is at a const. ratio to the relative bulk index of the finished sheet, this ratio being designated as the "H-factor." (2) In ideal calendaring (calendering in which the fibers are neither crushed nor gelatinized) of paper the percentage of apparent voids remains const. The bulk index of cellophane is about 0.45, which is taken as the lowest possible one for a sheet of cellulose; and relative bulk index is defined as the bulk index of the paper under consideration less the bulk index of cellophane. The H-factor varies according to the characteristics of the fibers used in the furnish, but is a const. for any given kind of fiber. In applying the method to the comparison of papers, the samples tested must have the same base wt. or a correction must be made to allow for the variation of voids and of bulk index with base wt. The method of making the detns. is described and the applications of the test are discussed. A. P.-C.

**Kraft paper.** R. DULOU. *Bull. inst. pin.* No. 57, 84-8(Feb., 1929).—A description of its manuf. A. PAPINEAU-COUTURE

**Fire-resistant papers.** WALTER OBST. *Wochbl. Papierfabr.* 59, 1270-2(1928).—Methods of prepn. are mentioned. R. H. DOUGHTY

**Wood paper from the eighteenth century.** TORSTEN ALTHIN. *Svensk Pappers-Tid.* 32, 14-17(1929).—A. describes early attempts in Sweden to make paper and mentions the work of H. Stakel in Helsingland in 1751 and refers to samples of his paper from sawdust and other materials. He refers especially to books of samples of old paper in the Royal Library of Sweden, gives six cuts of watermarks and illustrations, and adds a list of reference books on early paper making. W. SEGERBLOM

**Paper tests.** ROGER C. GRIFFIN. Arthur D. Little, Inc. *Paper Mill* 52, No. 7, 10, 12, 34(1929).—An address briefly outlining the chief tests which are applied to paper. A. PAPINEAU-COUTURE

**Study of the Weller brittleness test for paper.** R. L. PEEK, JR., AND J. M. FINCH. Bell Telephone Labs., New York. *Paper Trade J.* 88, No. 6, 56-62(1929).—In this test a sample of paper 0.25-1 in. wide and about 6 in. long is bent over the edge of a steel plate ground to form the half-circumference of a circle of about 0.005 in. radius, the plate forming the bar of a stirrup which is held in one jaw of a tensile testing machine, the 2 free ends of the sample being clamped together in the other jaw. The sample thus held is stretched by operating the testing machine in the usual way, and the load at which fracture occurs is noted. The difference between the load required to fracture a sample of the same dimensions in the ordinary tensile test and half the load required for fracture in the Weller test is supposed to be a measure of the brittleness of the paper; Bachman (*C. A.* 19, 1628) expresses this difference as a % of the load required for fracture in the tensile test and designates the result as % brittleness. In order that the best use may be made of the test in predicting the behavior in service of the material tested, P. and F. have made a theoretical and mathematical analysis of the test and for this purpose have assumed for the paper an ideal structure having properties which have been shown to be similar to those of paper. An equation is developed which theoretically relates the properties of the idealized paper to the conditions of the test. The expl. results conform sufficiently to those theoretically predicted to indicate that the treatment relates the quantities measured by the test to the factors upon which they are principally dependent and thus makes possible an interpretation of the relationships involved, approx. correct in essentials, although many minor factors are concededly

neglected. The complexity of the structure of paper suggests that any more accurate treatment would be exceedingly difficult, while the variability of the material is so great as to make it futile to attempt too precise a detn. of any of its properties. A. P.-C.

**Lithographic paper problems.** ROBERT F. REED. Lithographic Technical Foundation, Inc., Univ. of Cincinnati, Cincinnati, Ohio. *Paper Trade J.* 88, No. 10, 57-60; *Paper Mill* 52, No. 8, 76-88(1929).—The difficulties encountered in the lithographing of paper are discussed under the 4 headings: register troubles, greasing or scumming, difficulties related to the securing of satisfactory printing, problems in the application of adhesives. The difficulties are discussed from the point of view of the causes to which they may be traced, the known means by which they may be controlled, and the unknown factors involved. A program of research on the problems related to paper for lithographic purposes is suggested. A. PAPINEAU-COUTURE

**Notes on the coloring of paper.\*** J. NIEDERHAUSER. Établissements Kuhlmann. *Papier* 32, 85-7(1929).—A brief discussion of the merits of various dyes of French manuf. for the coloring of paper, particularly of the Diazol Lumière, Solanthrene and Luminol colors of the Établissements Kuhlmann. A. PAPINEAU-COUTURE

**The coloring of paper.** G. MARTIN. *Papeterie Special* No., 17-21(1928).—A brief review of the properties of the various classes of coloring matters used for coloring papers, and of the process of coloring paper. A. PAPINEAU-COUTURE

**The coloring of paper.** M. GOTTLÖBER. *Papier-Fabr.* 26, 577-81, 630-3, 679-81, 710-12, 783-7, 799-801(1928); 27, 3-8(1929); cf. C. A. 21, 1709.—A simple treatise on practical paper coloring. The Ostwald color theory (cf. C. A. 14, 492) is explained in detail, and its use as an aid in practical color work is discussed. The behavior of numerous common dyes in the beater, and the best methods for obtaining desired effects, are described. R. H. DOUGHTY

**The deterioration of paper.** W. F. HOFFMAN. Northwest Paper Co. *Paper Mill* 52, No. 8, 66, 68; *Paper Trade J.* 88, No. 12, 59-60(1929).—Attention is called to several factors in the manuf. of paper in which the alum content and the acidity of the furnish or the finished paper play a part. The optimum alum content of the furnish or the acidity as represented by the  $pH$  value cannot, in many cases, be based on any one factor, but must be based on all of the factors which enter into the manuf. of that particular paper, including: deterioration of the paper on aging, sizing, coloring, retention of filler, phys. properties of the finished paper, difficulties in operating the paper machines and effects of varying acidities on the paper mill equipment. A. P.-C.

**Fastness to light of colored paper.** WM. D. APPEL AND TH. C. BENTZEN. Whiting-Plover Paper Co., Stevens Point, Wis. *Paper Trade J.* 88, No. 9, 42(1929).—The relative fastness to light of colored papers can be detd. either by exposing them to sunlight or to C arc light, the Atlas Fade-ometer being probably as satisfactory as any instrument so far devised for the purpose, particularly the latest type which is provided with a fan to prevent excessive heating of the sample. For the quant. measurement of fading, the simplified method described previously (Appel, C. A. 22, 1043) can be used. A. PAPINEAU-COUTURE

**Retention of filler in paper.** G. K. SPENCE. New York and Pennsylvania Co. *Paper Mill* 52, No. 8, 50-4; *Paper Trade J.* 88, No. 12, 58-9(1929).—Detailed instructions are given as to the procedure which should be followed so as to obtain reliable results in making filler retention tests. The retention can also be obtained with much less trouble and with a satisfactory degree of accuracy from the following data: moisture, fiber and clay contents of the finished sheet; of the sheet passing from the wire to the first press (dry basis); of the stock in the water leaving the first press (dry basis); of the stock in the white water from the wire (dry basis); of the stock in the head box (dry basis); of the stock in the machine chest (dry basis); combined water content of the clay used and natural ash in the fiber mix. The method of calcn. is explained in detail by means of an example. A. PAPINEAU-COUTURE

**Action of liquids on paper.** JAMES STRACHAN. *Paper Mill* 52, No. 3, 24-6; No. 4, 24-6(1929).—A discussion of the penetrability of paper by liquids, more particularly from the standpoint of the penetration of writing ink and of printing inks into tub-sized and into engine-sized papers. A. PAPINEAU-COUTURE

**Report on permeability of paper to liquids.** ALLEN ABRAMS. Marathon Paper Mills Co., Rothschild, Wis. *Paper Mill* 52, No. 8, 112-6, 120; *Paper Trade J.* 88, No. 9, 40-2; *Pulp Paper Mag. Can.* 27, 423-5(1929).—A collaborative comparison of the curl test and of the dry indicator test, for measuring the degree of internal sizing. indicated that, on thin paper, either test may be used with reasonably concordant results; but the curl test made with the Carson curl sizing tester seems to give the most uniform data. Two methods for measuring greaseproofness along the lines of those

suggested by Smith (C. A. 22, 1853) gave results which varied widely on the same paper and by the same method.

**Decreasing two-sidedness of paper.** IVAR EKHOLM. National Aniline Co. *Pulp Paper Mag. Can.* 27, 283-4(1929).—A discussion of the causes of two-sidedness in paper, during the formation of the sheet at the wet end of the paper machine, during the drying process and on the calender, together with indications of how to eliminate or minimize it.

**Influence of pressing on the strength (of paper sheets).** ANON. *Papier-Fabr.* 26, 754-7(1928).—An unbleached Mitscherlich pulp was beaten to freenesses of 25, 50 and 75° Schopper, hand-dipped sheets were made, pressed between felts at pressures ranging from 0 to 130 atm. in steps of 10 atm. (method not stated), dried on an electrically heated cylinder and tested for breaking length. The strength increased about 15% between 0 and 60 atm., falling off again to about 10% below the original value at 130 atm. There is a marked break between 60 and 70 atm. pressure. The data are given in detail.

**Some lesser-known paper-making fibers.** J. STEWART REMINGTON. *Ind. Chemist* 5, 115-8(1929).—Lalang grass (*Imperata Cylindrica* Cyr), 47.41% cellulose, cooked with 15% NaOH for 10 hrs. at 135° gave a pulp yield of 48.21%. The pulp is suitable for printing purposes. Salt marsh grass (*Spartina juncea*), 36.16% cellulose, cooked with 12% NaOH for 10 hrs. at 60 lbs. pressure, gave a pulp yield of 37%. An alk. bleach gave the best results. The pulp is suitable for good wrapping paper; when mixed with 50% sulfite pulp and loaded, a good writing paper results. Fresh water cord grass (*Spartina cynosuroides*), 53.47% cellulose, cooked with 10% NaOH for 8 hrs. at 130°, gave a pulp that bleached easily in an acid bleach. The pulp is easily beaten, and makes a high-grade printing paper. Loaded pulp yields magazine stock. Combined with groundwood the pulp gives a good printing paper. The inner bark of *Adonsonia digitata*, 56.96% cellulose, cooked with 5% NaOH for 6 hrs. at 90 lbs. pressure, gave a pulp yield of 53%. The pulp is easily bleached. The pulp produces paper of excellent strength, good softness, rattle and feel. It mixes well with sulfite pulp. Delta grass was suitable for only low-grade papers where strength is unimportant.

**Quality of purified wood fibers.** ROYAL H. RASCH. Research Assoc., Bureau of Standards, Washington, D. C., for the Brown Co., Berlin, N. H. *Paper Trade J.* 88, No. 8, 233-63(1929).—The qualities of purified wood fibers and com. papers prepd. from these fibers have been investigated from the standpoint of chem. purity, color, durability and permanence and compared with other typical papers and paper-making fibers. In order to simulate as closely as possible the deteriorating effects of natural aging, and thus det. the probable relative permanence of various types of paper and paper-making fibers, accelerated aging treatments involving the exposure of samples to an elevated temp. were made and the extents of phys. and chem. degradation compared. It is not known how accurately such tests can reproduce the effects of natural aging; it seems reasonable, however, to suppose that materials possessing a high degree of stability toward the heat test would be correspondingly more permanently durable than those which manifest greater changes in chem. and phys. properties. The data obtained thus far point to the following general conclusions: (1) Accurate evaluation of the quality of papers or of the suitability of a pulp or half-stock for conversion into a given type of paper must be based on observations as to their performance under specified tests. Fiber compn. cannot be taken as a criterion of the excellence of a paper. The all-rag papers and wood-fiber papers which have been studied cover similar wide ranges of durability and permanence. (2) While it is desirable that the  $\alpha$ -cellulose content of a paper-making fiber intended for permanent uses should be as high as possible, conclusions based on this detn. alone may be in error because the non- $\alpha$ -cellulose constituents of different types of fibers vary, wt. for wt., in the extent to which they influence the permanence quality of these fibers. Modified celluloses are known to be active in causing rapid deterioration of cellulose; pentosans, on the other hand, appear to be relatively inert in this respect. (3) The decrease in the  $\alpha$ -cellulose content of a cellulose material caused by artificial aging is considered an indication of relative permanence. Purified wood pulps resemble the best grades of rag half-stock in suffering but slight changes in  $\alpha$ -cellulose after an exposure to a temp. of 100° for 72 hrs. In this respect purified wood fibers are considerably superior to poorer grades of rag fibers, such as old No. 1 white rag half-stocks. (4) Changes in the  $\alpha$ -cellulose content of papers brought about by artificial aging are accompanied by fairly proportionate changes in phys. properties, such as folding endurance and tearing resistance. It is therefore probable that the paper-making wood pulp and rag half-stocks which drop appreciably in  $\alpha$ -cellulose on heating would be unsuited for conversion into permanent

types of papers. (5) Purified wood fibers have excellent color characteristics, comparing favorably with half-stocks prepd. from the best grades of new white rags. Since they are relatively very resistant to the effects of artificial aging, it is indicated that they would show similar good resistance to the yellowing effect of natural aging. (6) Ordinary grades of sulfite pulps must be considered unsuited for conversion into highly permanent types of papers. Although such papers may have a degree of durability sufficient for most purposes, the character of the impurities present in the fibers is such as to cause relatively rapid deterioration and a consequent decrease in the initial strength qualities. (7) The better grades of soda pulps and the papers prepd. from them appear to be considerably more permanent than the ordinary sulfite pulps and papers. It is probable that high-grade soda pulp may be safely used in certain printing book papers where high-strength qualities are not essential, but where a fair degree of permanence is required. (8) A high degree of hydration appears to be detrimental to the permanence of a paper. (9) Mineral fillers may be safely added to furnishes for permanent papers, and probably aid to some extent in preventing deterioration. (10) High strength imparted by glue sizing is rapidly lost when the paper is heated. It is probable, however, that the surface coating of glue protects the individual fibers from deterioration somewhat by retarding oxidation, and thus increases the permanence of the paper. (11) The manner in which the purified wood fibers, and papers prepd. from them, reacted to the various tests which were applied, indicated that they were well adapted for use in high-quality bond and permanent-record papers, which have hitherto been made exclusively from furnishes of high-grade rag half-stock.

A. PAPINEAU-COUTURE

**Vulcanized fiber board.** JOSEPH ROSSMANN. U. S. Patent Office, Washington, D. C. *Paper Trade J.* 88, No. 5, 69-71(1929).—A brief description of the process of manuf. of vulcanized fiber board, together with abstracts giving a survey of the U. S. pats. for making vulcanized fiber board consisting of a no. of layers united together.

A. PAPINEAU-COUTURE

The color reaction of lignin (PODBREZNIK) 11D. Progress in the treatment of paper-mill wastes (HODGE) 14. Composition of sugar obtained by complete hydrolysis of pine wood (HÄGGLUND) 28. Hot-wall effect as a cause of corrosion (BENEDICKS) 9. Hadromal, lignin and coniferylaldehyde; preparation and identification of the last (PAULY, FEUERSTEIN) 10. Extraction and concentration of AcOH from dilute aqueous solutions (GUINOT) 10. Influence of sugars on the stability of bisulfite solutions (HÄGGLUND, *et al.*) 10. Progress in the chemistry of lignin (FUCHS) 10. Treating oil-soaked hemp waste (for production of fiberboard) (U. S. pat. 1,710,914) 25. Metallic paper (Ger. pat. 472,714) 18. Dispersion agents (from sulfite cellulose pitch) (Fr. pat. 648,728) 18. Road treatment with sulfite cellulose lyes (Fr. pat. 650,107) 20.

**Manufacture of Pulp and Paper.** Vol. IV. New 2nd ed. Prepared under direction of Joint Executive Comm. on Vocational Education, Representing the Pulp and Paper Industry of the U. S. and Canada. New York: McGraw-Hill Book Co., Inc. 598 pp. \$6.

**Cellulose.** I. G. FARBENIND. A.-G. Fr. 648,706, Feb. 15, 1928. Cellulose free from lignin is obtained by treating cellulose material suitably divided with the exact amt of a soln. of an alk. earth hypochlorite, contg. 2% active Cl, necessary to produce complete oxidation of the lignin, the process being carried out at a temp. not above 45° without external heating.

**Films of cellulose.** OTTO SINDL. Fr. 648,425, Feb. 4, 1928. In the production of films of cellulose, the soln. of cellulose comes in contact on one face with a surface in movement of the coagulating liquid so that coagulation takes place on this face before the other.

**Treating films, filaments and the like formed from cellulose solutions.** WOLFF & Co. and R. WEINGAND. Brit. 298,609, Oct. 12, 1927. Products such as those obtained from cuprammonium cellulose, viscose and like solns. are freed from hemicellulose, wood gum and like substances by treatment with alkali soln. and, to prevent after-formation of hemicellulose due to the alkali, may be treated with salt solns. or alc. before washing. Washing with water may be assisted by electroendosmosis with or without use of diaphragms and after washing the films may be neutralized with dil. acid and are suitable as supports for light-sensitive layers. Filaments thus treated have improved dyeing properties.

**Films, filaments, etc., from cellulose solutions or derivatives.** WOLFF & Co. and R. WEINGAND. Brit. 298,605, Oct. 12, 1927. The water-absorbent properties of

products formed from cellulose solns., such as cuprammonium cellulose and viscose or from cellulose ethers, are decreased by treating the film or other product with an org. liquid such as HOAc or formic acid and then applying a coating of a cellulose ester soln. such as collodion or cellulose acetate soln. The preliminary treatment insures the continuity of the coating. Alternatively, a water-immiscible softening agent may be incorporated in the film or other product by dissolving the softening agent in the org. liquid. Examples are given of the treatment of cellulose hydrate "foil," "viscose silk" and plates of regenerated cellulose.

**Cellulose and furfural from straw and similar materials.** VICKERS, LTD., and O. D. LUCAS. Brit. 298,800, Nov. 29, 1927. Material such as flax straw or wheat straw is first digested with water (suitably at 180° and under a pressure of 135 lbs. per sq. in. for 1-2 hrs.), and the resulting aq. soln. which contains furfural is drawn off and the furfural recovered from it by distn. The residue of cellulosic material may be used for making paper or other products.

**Elimination of the lignified portion of flax by chemical means in the manufacture of cellulose.** L. DE PESTELE and A. DUJARDIN. Belg. 353,112, Oct. 31, 1928. The material is cleaned, cut, heated to 100° in a weak alk. soln., pressed, subjected to intimate contact with Cl gas, washed with cold water, heated to boiling in a soln. of antichlor, made alk. and washed with boiling water.

**Acetylcellulose soluble in chloroform.** WOLFGANG GRUBER (to Alexander Wacker Ges. für elektrochemische Industrie). U. S. 1,711,314, April 30; Fr. 649,623, Feb. 23, 1928. Cellulosic material such as cotton, wood pulp or paper is treated with an acetylizing agent contg. ZnCl<sub>2</sub> (and which may also contain HOAc and Ac<sub>2</sub>O) at a relatively high temp. (suitably about 55-60°) until the cellulosic fibers have lost their structure, and the treatment is then continued at a lower temp. (suitably about 40°).

**Recovery of acetic acid in the preparation of acetylcellulose.** ALEXANDER WACKER GES. FÜR ELEKTROCHEM. IND. G. M. B. H. (Wolfgang Gruber, inventor). Ger. 473,833 Jan. 10, 1926. In the prepn. of acetylcellulose sol. in acetone, the AcOH is recovered by treating the AcOH liquor with mixts. of hydrocarbons or their chlorinated derivs. which ppt. the acetylcellulose and dissolve the AcOH, and which are non-miscible with concd. AcOH or glacial AcOH. The AcOH is removed by the addn. of the latter. The AcOH may also be removed from the hydrocarbon by fractional distn. Examples of hydrocarbons and concns. of AcOH with which they are non-miscible are given.

**Cellulose esters.** I. G. FARBENIND. A.-G. Fr. 649,576, Feb. 22, 1928. Esters of cellulose with higher homologs of AcOH are prepd. by causing cellulose to react with the anhydride of a halogen acetic acid in the presence of higher homologs of AcOH and a catalyst and hydrolyzing the esters obtained if necessary. In an example cellulose is added to a soln. of monochloroacetic anhydride and monochloroacetic acid in propionic acid. The mixt. is heated to 50-55° till a sample is sol. in C<sub>6</sub>H<sub>6</sub>. The ester of butyric acid made in the same way but hydrolyzed has the same qualities of soly.

**Cellulose esters.** HENRY DREYFUS. U. S. 1,711,110, April 30. In order to render cellulosic material, such as chem. wood pulp, more uniformly esterifiable to produce aliphatic acid esters such as cellulose acetate, the material is treated with a soln. of an alk. compd., such as dil. NaOH soln., previous to treatment with a lower aliphatic acid such as HOAc. U. S. 1,711,111 specifies pretreating the cellulosic material with a gas carrying vapors of a lower aliphatic acid such as HOAc and then esterifying the material in the presence of less than 3% the wt. of the cellulose of a condensing agent, such as H<sub>2</sub>SO<sub>4</sub>, and in the presence of HOAc in a quantity less than 6 times the wt. of the cellulose.

**Cellulose acetate.** J. W. BULMER. Brit. 298,819, Jan. 2, 1928. After-hydrolysis of cellulose acetate is effected in 2 stages, in the first of which there is added to the acetylation mixt. sufficient water to produce a mild hydrolysis of the cellulose acetate, which is then pptd., while in the second stage the pptd. material is treated with dil. acid for further hydrolysis.

**Coating surfaces with nitrocellulose and cellulose acetate compositions.** W. H. MOSS (to British Celanese, Ltd.). Brit. 298,608, Oct. 12, 1927. Metal, glass, wood or other surfaces are coated with a compn. contg. nitrocellulose and then with a compn. contg. cellulose acetate or other org. ester or ether of cellulose. Various details are given.

**Sodium cellulose waste.** VITTORIO CASABURI and ENRICO SIMONCINI. Ger. 472,680, Feb. 12, 1925. Condensation products, which have a tanning action, and their metallic salts are produced from the waste of Na cellulose by treating it with aromatic sulfo acids, hydroxysulfo acids, or aminohydroxysulfo acids. Aldehyde may be present. The products so obtained may then be treated with hydroxides of metals, such as Cr or Al, if required as salts. Thus, 25 kg.  $\beta$ -naphthol and 35 kg. H<sub>2</sub>SO<sub>4</sub> are

heated to 100–110° until a water-sol. compd. is produced. The soln. is diluted with 40 l. water and added to 150–160 kg. Na cellulose waste. The mass is stirred at 80–90° and 6 kg. of 40% of  $\text{CH}_3\text{O}$  added. The product contains 24–25% tanning material. Other examples mention 1-amino-8-hydroxynaphthalene-3,6-disulfonic acid, cresol and  $\text{H}_2\text{SO}_4$ , and naphthalene and  $\text{H}_2\text{SO}_4$ , as the aromatic acids to be used. The addn. of  $\text{Al}(\text{OH})_3$  or  $\text{Cr}(\text{OH})_3$  converts the tanning material into salts more suitable for certain kinds of tanning processes.

**Charging cellulose digesters.** P. A. FRÉSK. Swed. 64,364, Dec. 28, 1927. The charge is introduced into the digester by means of and together with a current of air, gas or steam. A rotary spreading device secures an even distribution of the materials in the vessel. Cf. C. A. 22, 3300.

**Mouth pieces for cigaret holders.** I. G. FARBENIND. A.-G. (Emil Schnabel, inventor). Ger. 473,701, Dec. 17, 1926. Cellulose derivs., such as acetylcellulose, are mixed with at least the same quantity of tobacco powder.

**Artificial silk from viscose.** K. LEUCHS. Brit. 298,688, June 18, 1927. Spun threads from viscose are supported on a foraminated Al carrier through which are successively passed liquids for desulfurizing and other treatments.  $\text{Na}_2\text{SO}_3$  is the preferred desulfurizing agent but various others are mentioned and details of the app. are given.

**Artificial silk.** ACÉTA G. M. B. H. Ger. 474,043, Mar. 4, 1927. The vertical cells used in the downward dry spinning of artificial silk are divided into 2 sections by a horizontal partition having a small aperture through which the filaments pass. The ascending currents of warm air in the 2 sections are drawn off independently through adjustable connections to a suction pipe, the chief portion being withdrawn at the upper part of the lower section. Perforations may be made in the walls sepg. adjacent cells, either in the upper section only or in both sections. The 2 sections may be heated to different temps.

**Artificial silk.** ACÉTA G. M. B. H. Fr. 649,334, Feb. 20, 1928. In dry spinning artificial silk downward against an ascending current of air, a spinning chamber is employed which is divided by an adjustable constriction into 2 compartments which both communicate at their upper ends in an adjustable and independent manner with the aspiration tube.

**Artificial silk.** BERGMANN ELEKTRICITÄTS-WERKE A.-G. Fr. 648,457, Feb. 6, 1928. An elec. centrifuge for spinning is described.

**Artificial silk.** MELITTA KLEIN. Fr. 648,379, July 6, 1927. The section of the orifices for the threads may be varied at will.

**Artificial silk.** MELITTA KLEIN. Fr. 648,397, June 22, 1927. Cellulose esters or ethers are spun downward in a closed chamber, fresh air entering at the top around the spinning nozzles. The chamber may be divided into 2 compartments sepd. by a diaphragm.

**Artificial silk.** Fr. KÜTTNER A.-G. Ger. 474,789, Mar. 15, 1927. The silk is spun into flat hanks which are pressed and washed.

**Artificial silk.** L. LILIENFELD. Brit. 298,548, May 6, 1927. "Viscose silk" having a high dry tenacity is formed by conducting a thread-like stream of viscose into a bath contg. instead of strong inorg. acids as used in the processes described in Brit. 274,521 and Brit. 274,690 (C. A. 22, 2273) an agent capable of coagulating viscose and an agent (which may be the same as the coagulating agent) capable of dissolving, swelling or plasticizing the coagulated thread. Various examples are given.

**Artificial silk.** ALPHONSE VERGÉ. Fr. 648,403, June 23, 1927. Stretching of artificial silk fibers is prevented by surrounding them with a rigid or elastic sheath, obtained by dipping the fibers in a bath contg. either (1) casein,  $\text{NH}_3$ , carob flour,  $\text{CH}_3\text{O}$  and water, (2) casein,  $\text{NH}_3$ , sebacic acid,  $\text{CH}_3\text{O}$  and water, (3) linseed oil, sebacic acid,  $\text{PhNH}_2$  or other amine and  $\text{C}_6\text{H}_6$  or tetrachlorethane or (4) solns. of rubber or artificial resins.

**Artificial silk from cuprammonia cellulose solutions.** LONZAWERKE ELEKTRO-CHEMISCH FABRIKEN GES. Brit. 299,022, Oct. 19, 1927. Artificial threads produced by the cupra-ammonia process are reduced in diam. by subjection to a drawing process while in a plastic condition obtained by washing with water or with a soln. of a suitable salt such as  $\text{MgSO}_4$  while the threads still contain Cu, as after coagulation in an alk. bath. Various mech. details of the drawing operation are described.

**Artificial threads from ammoniacal-copper cellulose solutions.** J. P. BEMBERG A.-G. Brit. 299,038, Oct. 20, 1927. The stretch-spinning method is so conducted that the threads leave the spinning funnel in a plastic condition and are subjected to a second considerable stretching after leaving the funnel. An arrangement of app. is described.

**Artificial fibers.** I. G. FARBENIND. A.-G. (Totila Madlung, inventor). Ger.

473,749, Sept. 16, 1927. The spinning head for artificial fibers is provided with an inflated rubber structure on which the fiber is wound as it is spun.

**Spinning artificial silk.** OSCAR KOHORN & Co. and ALFRED PERL. Fr. 649,087, Feb. 15, 1928. Means for cleaning the spinning nozzles are provided. Cf. C. A. 23, 982.

**Spinning artificial silk.** RAYMOND A. J. THÉNOZ and HENRY L. BARTHELÉMY. Fr. 649,126, July 6, 1927. Means are provided either in the interior or around the spinning head for circulating a liquid or gas at constant temp. to maintain a constant temp. in the collodion coming from the spinning nozzles. Cf. C. A. 23, 514.

**Preventing fraying of edges of cellulose derivative fabrics.** H. PLATT (to British Celanese, Ltd.). Brit. 299,042, Oct. 20, 1927. Edges, such as those of perforations for buttonholes or ornamental effects, in fabrics formed of cellulose derivs., are sealed to prevent raveling or fraying, by fusing, dissolving or softening the material at the edges and then permitting it to solidify.

**Multiple filament spinning nozzle for artificial silk.** HENRI COLCOMB. Swiss 130,382, Nov. 25, 1927.

**Rotary nozzle spinning for artificial silk.** THE NEURA ART-SILK Co., LTD. Ger. 473,935, Feb. 6, 1927.

**Wood-pulp material.** JOSEPH H. WALLACE (to Pine Waste Products, Inc.). U. S. 1,710,752, April 30. Pulp mill chips are prepd. from coniferous wood and contain a substantial proportion of the original resinous content of the wood distributed throughout the wood substantially uniformly (suitably by use of a solvent evenly to distribute the residual resin).

**Paper pulp.** PAPETERIES NAVARRE. Fr. 648,385, June 21, 1927. A paper pulp of superior quality is prepd. from colonial plants such as the *Cyperus papyrus* by submitting them to 2 distinct treatments, the 1st being confined to a mech. grinding with washing of the products with water, the 2nd being a light extn. with steam under atm. of slightly raised pressure with a small consumption of chem. agents, such as soda.

**Beater for paper pulp.** J. R. HAPPER. Brit. 299,150, Sept. 8, 1927. Structural features.

**Paper-making apparatus.** F. O. L. CHORLTON. Brit. 298,853, March 13, 1928. Structural features.

**Paper-making apparatus.** A. KOLITSCH. Brit. 298,653, Oct. 13, 1927. Variation in "vacuum" in the suction devices due to variation in the thickness of the paper being made serves automatically to regulate the supply of pulp stock to the flow box and to the wire cloth.

**Paper- and board-making apparatus.** ST. ANNE'S BOARD MILL Co., LTD., and R. B. HEYS. Brit. 298,671, July 14, 1927. Structural features.

**Apparatus for seasoning paper by treatment with electrically heated air.** GEORGE E. MAXNER. U. S. 1,710,706, April 30. An elec. heater is mounted within the air discharge nozzle.

**Drying plant for paper and fibrous materials.** WILLIAM B. FULTON. Ger. 474,829, July 11, 1926. The plant has groups of drying cylinders.

**Drying cylinder for paper and textiles.** EWALD LÜTSCHEN. Ger. 472,713, Mar. 15, 1927.

**Drying apparatus for pasteboard sheets.** "REFORM" FÜR HEIZ- U. TROCKENANLAG M. B. H. (Max Sauer, inventor). Ger. 474,905, Dec. 29, 1925. Details of arrangement.

**Means for dewatering paper and cardboard sheets.** FRIEDRICH DETTELBACH. Ger. 474,106, Oct. 1, 1925, and 474,107, May 2, 1926, addn. to 474,106. The means comprise a suction couch roll, a sec. couch roll, a perforated conveying band and, in 474,107, an auxiliary band.

**Device for testing the water-absorbing power of paper.** EUGEN STOTZ. Ger. 473,618, Mar. 5, 1927.

**Centrifugal machine for purifying paper-making materials.** HERMANUS THOMASSEN. Ger. 472,517, May 28, 1924. Addn. to Ger. 469,318 (C. A. 23, 1270). Details of construction.

**Apparatus for making coreless rolls of paper, etc.** CARL NEBRICH. Ger. 472,844, Dec. 25, 1927. Addn. to 469,675 (C. A. 23, 1270).

**Apparatus for preparing paper glazed on one side.** F. H. BANNING & SEYBOLD MASCHINENBAU-G. M. B. H. Ger. 472,842, July 2, 1926.

**Fireproofing paper, textiles, etc.** WESTFÄLISCH-ANHALTISCHE SPRENGSTOFF-A.-G. CHEM. FABRIK. Ger. 474,186, Mar. 1, 1925. The material is impregnated with a soln. of  $ZnNH_4$  chloride, a 30% soln. being suitable.

## -EXPLOSIVES AND EXPLOSIONS

C. E. MUNROE

**Striations in explosive flames.** G. B. MAXWELL AND R. V. WHEELER. *Nature* 122, 995(1928).—M. and W. observe, as have Egerton and Gates (*C. A.* 21, 2555), bands on photographs taken of flames propagated in cylinders. These bands indicate a vibratory nature of the combustion and may be due to a set of stationary waves compounded from sound waves reflected from opposite walls of the cylinder. G. G.

**Chemical composition for matches.** R. L. DATTA AND T. BASU. Dept. Industries, Bengal. *Bull.* 23, 4 pp.(1928).—Unsuccessful attempts were made to form a damp-proof compn. for matches by rendering the glue in it insol. by treatment with  $\text{CH}_3\text{O}$  or tannin before the remaining components were added. Compns. contg.  $\text{K}_2\text{Cr}_2\text{O}_7$  gradually became damp-proof as a result of the oxidation of the glue by this ingredient. B. C. A.

**Explosion limits of technical gas mixtures.** K. BUNTE AND A. STEDING. *Gas J.* 184, 728(1928).—Translation of an article reported in *C. A.* 23, 983. F. S. G.

**Explosion regions of some gas and vapor mixtures in which carbon monoxide is the only or the principal inflammable gas.** J. H. A. P. LANGEN VAN DER VALK. *Rec. trav. chim.* 48, 201-19(1929).—Explosion limits were detd. in a glass buret, ignition being by jump spark. Elaborate precautions were taken to insure purity of gases and cleanliness of app. (A) Explosion limits of CO and air mixts. were narrowed by the addn. of increasing amts. of trichloroethylene, perchloroethylene, tetrachloroethane, and pentachloroethane. The explosion limits of dichloroethylene are 3.25% and 15% (vol.) at 14° and 760 mm. The explosion limits of CO and air mixts. are widened by addn. of dichloroethene; therefore this compd. may be dangerous in some industrial applications. (B) In the presence of 3%  $\text{CCl}_4$  no explosion occurs with mixts. of CO and air from 20 to 45% CO. Thus, somewhat more than 1%  $\text{CCl}_4$  will prevent explosions of CO and air. Four %  $\text{CHCl}_3$  prevented explosions of CO and air mixts. between 5 and 40% CO; 3%  $\text{CHCl}_3$ , between 25.5 and 38.5% CO; 2%  $\text{CHCl}_3$ , between 22.5 and 45.5% CO. Methylene dichloride lowers both explosion limits of CO and air mixts., no explosion being possible above 20% methylene dichloride. The explosion limits of  $\text{MeCl}$  are 16.3 to 24.4% with air. The compd. narrows the explosion limits of CO and air mixts. to 2.35% to 28.95% CO with 22%  $\text{MeCl}$ . (C) Mixts. of CO,  $\text{CH}_4$ , air, and a fourth "extinguishing" substance such as  $\text{CCl}_4$  were investigated. (D) Tests were made on the influence of excess  $\text{O}_2$  and  $\text{N}_2$ , leading toward the detn. of a closed explosion region. The results of parts C and D can be given only by data in the original paper. C. Z. ROSECRANS

Reactions carried out under high pressure (BERL) 2. Preparation of a solution containing  $\text{H}_3\text{PO}_4$  direct from bone ash for the impregnation of match sticks to render them non-glowing (DATTA, BASU) 18.

**Smokeless propellant explosives.** F. I. DUPONT, E. DUPONT and U. S. F. POWDER CO. *Brit.* 298,543, April 7, 1927. A substantially dry finely divided mixt. of oxidizing substance such as  $\text{KNO}_3$  or  $\text{K}_2\text{Cr}_2\text{O}_7$  and an oxidizable substance such as charcoal is intimately mixed with nitrocellulose before or during gelatinization or before the gelatinized nitrocellulose has become hardened, with or without nitroglycerin and other ingredients. From 0.5 to 25% of the added oxidizing and oxidizable substances may be used and these may be supplied in the form of black powder if desired.

**Explosives comprising 2,4,6-trinitro-1,3,5-triazidobenzene.** O. TUREK. *Brit.* 298,629, Oct. 13, 1927. This compd. is used either alone or with other substances as an explosive charge in blasting cartridges, percussion caps, detonators, detonating fuses and projectiles. A layer of Pb azide may be pressed on the charge.

**2,4,6-Trinitro-1,3,5-triazidobenzene as an explosive.** O. TUREK. *Brit.* 298,981, Oct. 18, 1927. This compd. is formed by treating 2,4,6-trichloro-1,3,5-trinitrobenzene with an alkali azide in a solvent such as alc., acetone or water. It is an active explosive and when melted is converted into hexanitrosobenzene.

**Trinitrotoluene.** AKTIENGESSELLSCHAFT LIGNOSE. *Fr.* 649,345, Feb. 21, 1928. See *Brit.* 294,625 (*C. A.* 23, 2036).

**Nitroglycerin.** ARNOLD SCHMID. *Fr.* 649,452, Jan. 31, 1928. For the sepn. of nitroglycerin and residual acid, the operation is carried out in thin layers, the liquid being either stagnant or in slow movement in the layers. *Fr.* 649,453 describes an app. for washing nitroglycerin and like esters.

**Nitroglycerin.** ARNOLD SCHMID. Fr. 649,774, Jan. 31, 1928. In the nitration of glycerol the reaction mixt. is given an intense circulation through 2 successive compartments which are sepd. but communicate at 2 points. One of the compartments has cooling coils with narrow spaces through which the liquid is driven. The 2nd chamber has no coils but contains an agitator which causes the circulation through the 2 chambers.

Use of bakelite or similar moldable composition for making projectile fuzes. Soc. ITALIANE POLVERI ESPLODENTI. Brit. 298,948, Oct. 17, 1927.

**Denitrating residual nitrating acids, etc.** A. SCHMID and J. MEISSNER. Brit. 298,894, Oct. 15, 1927. Residual  $\text{H}_2\text{SO}_4$  mixt. such as that from manuf. of nitroglycerin is denitrated by heating in a vacuum such that most of the  $\text{HNO}_3$  is sepd. before a temp. is reached at which org. substances are acted on. Subsequent reaction with org. substances serves to remove remaining  $\text{HNO}_3$  and leave pure  $\text{H}_2\text{SO}_4$ . A vacuum of 190–200 mm. Hg and a temp. of  $120^\circ$  are suitable for the first stage of the process and a temp. of  $145\text{--}50^\circ$  may be attained in the second stage. An app. is described.

## 25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

**History of the development of fast dyeing and dyes.** JAMES MORTON. *J. Roy. Soc. Arts* 77, 544–74 (1929).—See *C. A.* 23, 2574. E. H.

**Method of preparation of salts of naphtholsulfuric acid with organic bases (aromatic series), and their application in dyeing wool and silk by diazotization on fiber.** E. I. ORLOV. *Ukrainskii Khim. Zhurnal* 3, Tech. part, 181–2 (1928).—Seventy-two parts of  $\beta$ -naphthol are mixed with 110 parts of  $\text{H}_2\text{SO}_4$ , d. 1.84, and the resulting naphthol-sulfuric acid is combined with an org. aromatic base to a salt, from which by subsequent diazotization is obtained a dyestuff. The prepd. salt is dissolved on boiling in  $\text{H}_2\text{O}$ , some Na acetate is added, the soln. is filtered boiling hot, and wool or silk (fabric or yarn previously washed with 1%  $\text{Na}_2\text{CO}_3$  or soap) is steeped in the hot bath, the fiber is removed and wrung out, and diazotized on fiber in a cold  $\text{NaNO}_2$  bath, after which it is rinsed in a 1% AcOH bath, washed thoroughly in boiling  $\text{H}_2\text{O}$ ; this is repeated 2–3 times to remove the yellow tinge from the fiber. The bases and the corresponding proportions used are: 70 parts of *p*-nitroaniline-red, 72 parts of  $\alpha$ -naphthylamine-brown, 61 parts of dianisidine-lilac, safranine-violet,  $\beta$ -naphthylamine. This method is of interest because the usual method of dyeing vegetable matter by direct diazotization on the fiber is not applicable to animal fiber as  $\text{HNO}_3$  has a destructive action on it.

CHAS. BLANC

**Preparation of new nitro colors.** P. P. KARPUGHIN. *Ukrainskii Khim. Zhurnal* 3, Tech. part, 233–5 (1928).—To 100 g.  $p\text{-ClC}_6\text{H}_4\text{NO}_2$  in 100 g.  $\text{H}_2\text{SO}_4$ ,  $\text{H}_2\text{O}$  at  $50^\circ$  was added 80 g. of oleum contg. 25% of  $\text{SO}_3$  and the mixt. heated for about 2 hrs. to  $110^\circ$  until completely sol. in  $\text{H}_2\text{O}$ , giving mainly  $2,5\text{-O}_2\text{NCIC}_6\text{H}_3\text{SO}_3\text{H}$ . To this was directly added 70 g. of  $\text{HNO}_3$  (d. 1.4) at a temp. not over  $60^\circ$ ; then the mixt. was heated for 30 mins. to  $120^\circ$ , cooled, 250 g. of ice and 300 cc. of  $\text{H}_2\text{O}$  were added, the dinitrochlorobenzenesulfonic acid (I) was salted out with 200 g. of NaCl, filtered and dried.  $m\text{-C}_6\text{H}_4(\text{NH}_2)_2$  (10.6 parts, 0.1 mol.) was dissolved in 200 parts of  $\text{H}_2\text{O}$ ,  $1/8$  mol. of I was introduced, then  $1/4$  mol. of  $(\text{NH}_4)_2\text{CO}_3$  to neutralize freed HCl, and the mixt. was heated at  $60^\circ$  for 3 hrs. and the color salted out with 40 g. of NaCl. The color dyes wool in acid bath 5% with golden brown color. Under similar conditions 2,4-diaminodiphenylamine gives a color that dyes wool in acid bath 4% with reddish brown color. The condensation of I with aniline produces a yellow color that dyes wool 10% with poor fastness to light and washing. With increasing size of mol. and accumulation of diphenylamine groups the color deepens and the fastness is augmented.

CHAS. BLANC

**Woolen and worsted cloth analysis.** III. GEORGE PRIESTLEY. Univ. of Leeds. *Textile Recorder* 46, 49–50 (1929); cf. *C. A.* 23, 2575.—The use of cotton, rayon, linen, jute and ramie in admixture with wool is considered. RUBY K. WORTNER

**Bleaching of muslin.** HARUKAJE UTAKE. Osaka Industrial Research Laboratory. *Repts. Imp. Ind. Research Inst., Osaka, Japan* [9], 8, 70 pp.—Two bleaching agents were employed:  $\text{NaHSO}_3$  and  $\text{H}_2\text{O}_2$ , different concns. being used. In order to test the effect of different bleaching methods, bleached muslin was dyed with several dyes. The amount of dye used was calcd. Other physical properties of bleached muslin were also examd.

**Transverse sections of artificial silk. II. Changes in section during moistening with water.** Y. KAMI AND S. NAKASHIMA. *Cellulose Ind.* (Tokyo) 4, 206-9 (1928); cf. C. A. 22, 163, 1047.—The cross-sectional area of filaments of well-known brands of artificial silk increased by 50-60% after soaking in water, while the periphery alters but little. The filament tends to regain its original form when first coagulated. Reverse changes occur during drying. B. C. A.

**The strengthening of viscose.** L. MEUNIER and R. GUYOT. *Rev. gén. colloïdes* 7, 53-66 (1929).—The hydrophylic properties of cellulose fibers are a function of the no. of free hydroxyl groups, which, because of their strongly polar character, react readily with water. The variations of the hydrophylic properties of viscose have been studied when the alc. hydroxyl groups are transformed by pairs in groups  $O-CH_2-O$  by means of formaldehyde. The removal of these groups affects the strength of the viscose absorption of substantive dyes and resistance to alkalis. L. B. MILLER

**Dyes.** BRITISH DYESTUFFS CORP., LTD., and JAMES BADDILEY. Fr. 648,843, May 24, 1927. Cotton and regenerated artificial silk are dyed with secondary disazo dyes obtained by coupling a diazotized nitroarylamine or a homolog or deriv. thereof, free from sulfo or carboxy groups, with a coupling component, diazotizing and coupling in alk. soln. with a 1,8-aminonaphtholsulfonic acid or a *N*-substituted deriv. thereof. The nitro group may be reduced. The following dyes are specified in examples: *p*-nitroaniline + 1-naphthylamine-6 (and 7)-sulfonic acid + 1,8-aminonaphthol-4-sulfonic acid gives a dull blue shade; *p*-nitroaniline + *m*-amino-*p*-cresol Me ether + 1,8-aminonaphthol-3,6-disulfonic acid, and reduction of the nitro group, yields a greenish black shade, the fastness of which to washing may be increased by diazotizing on the fiber and developing with *m*-tolylene diamine. A table of suitable primary, middle and final constituents and the colors obtained with the dye produced are given. Cf. C. A. 22, 3994

**Mordant dye.** DURAND & HUGUENIN AKT.-GES. Swiss 130,615, July 7, 1926. Addn to Swiss 123,930. A mordant dye is prepd. by diazotizing the amino group in *p*-amino-*m*-sulfo benzeneazosalicylic acid and coupling with *m*-cresotinic acid. With a Cr mordant, the dye colors cotton a fast brownish orange. Cf. C. A. 23, 2303.

**Dyes.** I. G. FARBENIND. A.-G. Brit. 298,545, June 7, 1927.  $\mu$ -Anthraquinonyl-anthraquinoneoxazoles are prepd. by condensation of  $\alpha$ -aminohydroxyanthraquinones with anthraquinone aldehydes or compds. capable of furnishing them such as azomethine of anthraquinone aldehydes or  $\omega$ -dichloromethylanthraquinones, or by condensation of the anthraquinonyl amides of anthraquinone carboxylic acids or components furnishing them such as an anthraquinone isoxazole and an aminoanthraquinone substituted in the  $\alpha$ -position to the amino group by OH or a neg. substituent. Either of the anthraquinone residues may contain addnl. substituents. The products which contain at least 1 free amino group may be converted into dyes of deeper color by

treatment with oleum, with or without addn. of catalysts such as S or I. The resulting compds. change color by the action of alkalis but this may be avoided by alkylation (suitably with *p*-toluenesulfonic acid methyl ester). Numerous examples are given of the production of dyes by this method. 2,3-Aminohydroxyanthraquinone is formed by treating 2,3-bromohydroxyanthraquinone with concd.  $\text{NH}_3$  at  $130^\circ$ . Reference is made to condensation products from anthraquinone-2-carboxylic chloride and 2-amino-1,3-dibromoanthraquinone and from 1-aminoanthraquinone-3-carboxylic chloride and 2,3-bromoanthraquinone.

**Dyes.** I. G. FARBERIND. A.-G. Brit. 298,696, July 18, 1927. Dianthraquinonylamines contg. a benzoylamino group in each anthraquinone nucleus, and also at least one alkoxy group, are prepd. by processes of which several examples are given, among which are the following: (1) a halobenzoylaminoanthraquinone is condensed with an aminohydroxybenzoylaminoanthraquinone and the product alkylated; (2) a halo-hydroxybenzoylaminoanthraquinone is condensed with a benzoylaminoanthraquinone contg. at least 1 free amino group, and the product is alkylated; (3) a haloalkoxybenzoylaminoanthraquinone is condensed with an aminobenzoylaminoanthraquinone; (4) a halo-hydroxybenzoylaminoanthraquinone is condensed with an aminohydroxybenzoylaminoanthraquinone and the product is alkylated; (5) a haloalkoxybenzoylaminoanthraquinone is condensed with an aminoalkoxybenzoylaminoanthraquinone. Numerous specific examples are given. 1-Benzoylamino-4-hydroxy-5-chloroanthraquinone and 1-benzoylamino-4-methoxy-5-chloroanthraquinone are formed by benzoylation of the corresponding amino derivs. 1-Benzoylamino-4-hydroxy-5-aminoanthraquinone is formed by partial hydrolysis of 1,5-dibenzoylamino-4-hydroxyanthraquinone. 1-Benzoylamino-4-methoxy-5-aminoanthraquinone is formed by condensation of 1-benzoylamino-4-methoxy-5-chloroanthraquinone with *p*-toluenesulfonamide and hydrolysis of the sulfonamido group. 1-Amino-4-hydroxy-5-chloroanthraquinone is made by the reduction of 1-nitro-5-chloroanthraquinone with "S sesquioxide" or by rearrangement of 1-hydroxyamino-5-chloroanthraquinone or by nitration and reduction of 1-hydroxy-8-chloroanthraquinone. 1-Methoxy-8-chloroanthraquinone is made by the action of  $\text{MeOH-KOH}$  on 1,8-dichloroanthraquinone or 1-nitro-8-chloroanthraquinone. 1-Amino-4-methoxy-5-chloroanthraquinone is made by nitration and reduction of 1-methoxy-8-chloroanthraquinone.

**Dyes.** I. G. FARBERIND. A.-G. (Arthur Lüttringhaus, Hugo Wolff and Heinrich Neresheimer, inventors). Ger. 473,163, Feb. 23, 1926. Benzanthrone or a deriv. having the *Bz*-1-position either free or substituted with halogen or with a group contg. O or S is treated with an acid halide in the absence of strong catalysts or condensing agents, and the halogenated products so obtained are sapond. under acid conditions and, if desired, simultaneously or subsequently oxidized. Dyes of the dibenzanthrone or isodibenzanthrone series dyeing cotton in violet shades are so obtained. According to the examples: (1) benzanthrone is treated with  $\text{PhCOCl}$  and the product is sapond. with  $\text{H}_2\text{SO}_4$ ; (2) the product of (1) is oxidized with  $\text{HNO}_3$ , Br or  $\text{MnO}_2$ ; (3) benzanthrone is treated with  $(\text{COCl})_2$  and the product is sapond. with  $\text{H}_2\text{SO}_4$ ; the 2,2'-dibenzanthronyl so obtained may be treated directly with  $\text{MnO}_2$ , yielding a dihydroxybenzanthrone, or with  $\text{HgO}$ , yielding dibenzanthrone or a dibenzanthrone sulfonic acid; (4) as in (1), using *Bz*-1-thiocresylbenzanthrone or 6-chloro-*Bz*-1-thiocresylbenzanthrone and *o*-chlorobenzoyl chloride; (5) as in (1), using *Bz*-1-chloro- or bromobenzanthrone and  $\text{POCl}_3$ ; (6) as in (1), using *Bz*-1-phenoxybenzanthrone and *o*-chlorobenzoyl chloride.

**Soluble dyes.** I. G. FARBERIND. A.-G. Fr. 649,219, Feb. 17, 1928. Dyes sol in water are obtained by condensing in the 2 amino groups diaminodiphenyl, its derivs. or substitution products, with a halonitrosulfonic acid of the  $\text{C}_6\text{H}_5$  or  $\text{C}_{10}\text{H}_7$  series contg. replaceable halogen atoms. In examples, benzidine (1 mol.) is heated with K 1-chloro-2,6-dinitrobenzene-4-sulfonate (2 mols.) and calcined soda in water. The product dyes wool orange shades. Dyes are also obtained from (1) 2,4'-diaminodiphenyl and 1-chloro-2,6-dinitrobenzene-4-sulfonic acid, (2) dianisidine and 1-chloro-2,6- (or -2,4-) dinitrobenzene-4-sulfonic acid, (3) 4,4'-diamino-2-nitrodiphenyl, or benzidine, or dianisidine and 1-chloro-2,6-dinitrobenzene-4-sulfonic acid, (4) benzidine or nitrobenzidine or *o*-dianisidine and 1-chloro-2-nitrobenzene-4-sulfonic acid. In each case the 2 amino groups become substituted with elimination of  $\text{HCl}$ .

**Dyes.** IMPERIAL CHEMICAL INDUSTRIES, LTD., R. W. PORG and M. WYLER. Brit. 299,152, Sept. 8, 1927. Oxyphenazines, naphthophenazines and dinaphthazines are treated with an alkali bicarbonate or with  $\text{CO}_2$  in the presence of an alkali and the resulting oxycarboxazines may be thionated to form S dyes.

**Dyes.** KURT LINDNER. Ger. 472,975, Dec. 22, 1925. A finely ground body

dye is prepd. with coal-tar, animal or vegetable dyes as the foundation, by the addn. of finely powd.  $\text{H}_2\text{SiO}_3$  obtained from the decompn. of sol. fluosilicates or  $\text{SiF}_4$ .

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 130,317, Dec. 4, 1926. Addn. to Swiss 127,259 (C. A. 23, 1281). Diazotized 4-acetamino-2-amino-1-benzenesulfonic acid is coupled with 1-(2'-methyl-5'-sulfonic acid)-phenyl-5-pyrazolone-3-carboxylic acid. The new dye colors wool in fast green-yellow tones in  $\text{H}_2\text{SO}_4$  baths.

**Dye.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 130,616, July 21, 1927. Addn. to Swiss 119,986. A vat dye of the dibenzanthrone series is prepd. by treating dibenzanthrone with  $\text{FeCl}_3$ . The dye colors cotton a wash-fast blue.

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 130,620 and 130,621, Feb. 12, 1927. Addns. to Swiss 127,530 (C. A. 23, 1284). New dyes of the anthraquinone series are prepd. by the action of 1-methoxy-4-aminoanthraquinone on dimethyl-*p*-phenylenediamine or on *m*-phenylenediamine. Thus, 25.4 parts of 1-methoxy-4-aminoanthraquinone are heated with 40 parts of *m*-phenylenediamine and 100 parts of dimethylaniline at  $180^\circ$  until a test in alc. showed no further change in color. MeOH at  $100^\circ$  is added. On cooling and filtering, the dye 1-(3'-amino)-phenyl-4-aminoanthraquinone is obtained. It colors acetate silk blue.

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 469,248. June 3, 1925. Addn. to Ger. 425,352. Indigoid dyes and their intermediate products are prepd. by a modification of the process described in the prior patent and in Ger. 427,905, by first prepg. the corresponding anil of thiofuran-1,2-dione by the action of an aromatic nitroso compd. on 2,3-anthraquinone or 2,3-anthraceneoxythiophene, and then condensing the anil of 2,3-anthracenethiofuran-1,2-dione with 2,3-anthraquinoneoxythiophene, or the anil of 2,3-anthraquinonethiofuran-1,2-dione with 2,3-anthraceneoxythiophene. Thus, 2,3-anthraquinoneoxythiophene, alc., water and 30% NaOH were warmed together to  $40^\circ$  and a soln. of nitrosodimethylaniline in alc. was added. Blue crystals of 2,3-anthraquinonethiofuran-1,2-dione are formed. Another example is given.

**Dyes.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Ger. 469,249. May 23, 1923. Indigoid dyes are prepd. by condensing the halogen substitution products of 2,1-naphthoxythiophene with 2-anil or 2-halide cyclic *o*-diketone, and, if desired, halogenating the product. Thus, dibromoisatin is suspended in chlorobenzene and heated with  $\text{PCl}_5$ . The resulting soln. of dibromoisatin chloride is stirred with a soln. of 7-chloro-2,1-naphthoxythiophene in chlorobenzene. The dye is pptd. as brown powder which, in a yellow vat, colors cotton gray-brown and silk red. With isatinilide, a product which colors cotton violet-red is obtained. Other examples are given.

**Azo dyes.** BRITISH DYESTUFFS CORP., LTD., JAMES BADDILEY, PERCY CHORLEY and RAINALD BRIGHTMAN. Ger. 474,301, Nov. 19, 1926. See Brit. 270,446 (C. A. 22, 1691).

**Azo dyes.** I. G. FARBERIND. A.-G. Brit. 298,697, July 18, 1927. Azo dyes insol. in water are formed in substance, on the fiber or on a substratum by coupling diazotized unsulfonated aminofluorenes with components such as naphthols, 2,3-hydroxynaphthoic arylides, hydroxynaphthocarbazoles or diacetoacetyl or like derivs. of aromatic diamines. Several examples are given.

**Azo dyes.** I. G. FARBERIND. A.-G. Brit. 298,907, Oct. 13, 1927. Azo dyes are formed in substance, on a substratum or on the fiber by coupling a diazotized 2,5-dimethyl-4-halogenaniline with an arylide of 2,3-hydroxynaphthoic acid or an arylide of a  $\beta$ -ketocarboxylic acid. Cotton is dyed red by padding with a soln. of the 4'-aniside or 2',5'-dimethoxy-1'-anilide of 2,3-hydroxynaphthoic acid and developing with a soln. of diazotized 2,5-dimethyl-4-chloroaniline or of 2,5-dimethyl-4-bromoaniline.

**Azo dyes.** I. G. FARBERIND. A.-G. Brit. 298,518, July 6, 1927. Many examples are given of the manuf. of tetrakisazo dyes of the type  $\text{R}^1\text{—R}^2\text{—R}^3\text{—R}^4\text{—X}$  and of octakisazo dyes of the type  $\text{R}^1\text{—R}^2\text{—R}^3\text{—R}^4\text{—Z—R}^5\text{—R}^6\text{—R}^7\text{—R}^8$ , in which  $\text{R}^1$  is an aromatic amine,  $\text{R}^2$  is a diazotizable middle component of the naphthalene series,  $\text{R}^3$  is a deriv. of a sulfonated or unsulfonated 1-naphthylamine, coupled in *p*-position to the amino group and contg. a free or substituted OH group,  $\text{R}^4$  is a deriv. of 2,5,7-aminonaphtholsulfonic acid contg. a diazotizable amino group in the heteronuclear side chain (or a deriv. thereof substituted also in the 1-position), and X and Z are one of the following coupling components: methyl ketol or a substitution product, a pyrazolone, a deriv. of a  $\beta$ -ketoaldehyde, 6,8-dihydroxyquinoline, a sulfazone of the type

$\text{CH}_3\text{—SO}_2\text{—CH}_2\text{—CO—NH}$  or salicylic acid or a deriv. capable of coupling.

**Azo dyes.** I. G. FARBERIND. A.-G. (Hans Krzikalla, inventor). Ger. 474,997, Aug. 29, 1926. Complex metal compds. of *o*-hydroxyazo dyes are formed by treating

the dye with compds. of such metals as Cr. Thus, 41 parts of the dye obtained by diazotizing 4-chloro-2-anisidine and 2,6-naphtholsulfonic acid are heated to 125–130° under pressure for 7 or 8 hrs. with 600–700 parts water, 40 parts  $\text{Cr}_2\text{O}_3 \cdot n\text{H}_2\text{O}$  contg. 26%  $\text{Cr}_2\text{O}_3$  and 20–25 parts 80%  $\text{CH}_2\text{O}$  in an autoclave. The Cr compd. is salted out in the usual way and colors wool a wash- and light-fast violet. Other examples are given.

**Azo dye.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 130,425, July 26, 1927. Diazotized 2-naphthylamine-1-sulfonic acid is coupled with 5-pyrazolone-3-carboxylic acid. The dye colors wool yellow. Cf. C. A. 23, 2833.

**Azo dye.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Ger. 474,746, Sept. 30, 1923. An *o*-hydroxyazo dye is prepd. by sapong. the reaction product of 1 mol. of unnitrated *o*-diazophenolsulfonic acid or one of its hydroxyacid derivs., and 2 mols. of unsulfonated  $\beta$ -naphthylamine. Thus, 189 parts *o*-aminophenolsulfonic acid are diazotized and stirred with 359 parts of  $\beta$ -naphthylamino-HCl at 40–85°. The product is treated with cold NaOH. The *o*-aminoazo dye produced colors wool orange in an acid bath. Cf. C. A. 23, 2577.

**Azo dyes for cellulose esters.** OSKAR KNECHT (to Chemische Fabrik vorm. Sandoz). U. S. 1,711,390, April 30. In prep. dyes contg. neither  $\text{CO}_2\text{H}$  nor  $\text{SO}_3\text{H}$  groups and suitable for dyeing cellulose acetate or other cellulose esters, diazotized glycol 2-amino-4-nitrophenyl ether or other suitable diazo compd. having at least one H atom of its aromatic nucleus substituted by a radical of glycol is coupled with an azo component such as *m*-toluidine; the dye may be developed with  $\beta$ -naphthol. U. S. 1,711,391 specifies a like process, using compds. with a radical of glycerol such as glycerol 2-amino-4-nitrophenyl ether.

**Azo dyes containing chromium.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Swiss 130,155, June 24, 1927 and 130,156, July 28, 1927. The dye obtained from the nitrated diazo compd. of 1-amino-2-hydroxynaphthalene-4-sulfonic acid and  $\beta$ -naphthol is heated with  $(\text{HCOO})_3\text{Cr}$  in presence of  $\text{AcONa}$  to give a Cr-contg. azo dye. In the second patent, a Cr-contg. azo dye is prepd. by treating the dye obtained from diazotized 6-sulfo-4-chloro-2-amino-1-phenol and  $\beta$ -naphthylamine with an org. Cr salt in the presence of an org. acid.

**Azo dye containing chromium.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Ger. 473,527, Jan. 26, 1926. An azo dye contg. Cr is prepd. by treating the azo dye obtained from 6-nitro-2-amino-1-phenol-4-sulfonic acid and  $\beta$ -naphthol with Cr-yielding materials, such as  $\text{CrF}_3$ ,  $(\text{AcO})_3\text{Cr}$  or freshly pptd.  $\text{Cr}(\text{OH})_3$ .

**Metal compounds of azo dyes.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. Brit. 298,494, Oct. 8, 1927. Azo dyes contg. metal such as Cu or Cr, with or without other suitable compds., are condensed with cyanuric halides. A very large no. of examples are given of dyes producing different shades and suitable for use on various materials including cotton, wool and silk. Cf. C. A. 23, 2833.

**Vat dyes.** I. G. FARBENIND. A.-G. (Karl Schirmacher, Hans Tampke and Wilhelm Schaich, inventors). Ger. 472,772, Oct. 22, 1926. Addn. to 470,809. The method of Ger. 470,809 (C. A. 23, 2043) for the manuf. of vat dyes from the 9,10-disulfuric acid esters of certain anthrahydroquinones is now found to be applicable to the corresponding 9,10-diethers. In 1 example,  $\beta$ -acetaminoanthraquinone is reduced catalytically with H and the product etherified with  $\text{Me}_2\text{SO}_4$ . The  $\beta$ -acetaminoanthrahydroquinone-9,10-dimethyl ether, m. 253°, so obtained is sapon. to give  $\beta$ -aminoanthrahydroquinone-9,10-dimethyl ether, m. 235°, and the hydrochloride of the ether is then oxidized by boiling in aq. HCl suspension with  $\text{FeCl}_3$ . Finally, the oxidation product is warmed with  $\text{H}_2\text{SO}_4$  to split off the ether groups. The product is a vat dye giving blue shades on cotton. In another example, the same product is obtained starting from  $\beta$ -formylaminoanthraquinone and effecting the oxidation of the ether with  $\text{NaOCl}$ .

**Vat dye.** I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 473,664, July 6, 1927. Vat dyes are prepd. by the action of alcs., phenols or mercaptans on neg. substituted *allo*-*ms*-naphthodianthrone, with or without solvent or suspension agent, and, if desired, in the presence of agents with an alk. reaction. The product may be halogenized. Thus, 100 parts dichloro-*allo*-*ms*-naphthodianthrone are stirred with 200 parts KOH and 1000 parts PhOH and boiled until the soln. is violet-red. The liquid is cooled to 80–100°, and 2000 parts spirits added. A blue-red product is formed and is filtered off and recrystd. from  $\text{PhNO}_2$  as red needles m. about 315°. If the PhOH is replaced by other substances contg. the OH or SH groups, such as *p*-cresol,  $\beta$ -naphthol,  $\beta$ -hydroxyanthraquinone, or  $\text{PhSH}$ , a dye with similar properties is obtained. Other examples are given. Cf. C. A. 23, 2042.

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 648,861, Oct. 21, 1927. Compds. of the

formula  $2,3\text{-MeXC}_6\text{H}_3\text{SCH}_2\text{CO}_2\text{H}$  (I), where X is either CN,  $\text{CONH}_2$  or  $\text{COOH}$ , are condensed to obtain the corresponding hydroxythionaphthene and the latter is transformed by the usual methods into vat dyes. In examples, 3-methylbenzene-2-cyano-1-thioglycolic acid (6-nitro-*o*-toluidine by converting the  $\text{NH}_2$  into CN, reducing the  $\text{NO}_2$  group and introducing the thioglycolic acid group by diazotizing) is heated with NaOH soln. and the Na salt of 4-methyl-3-amino-1-thionaphthene-2-carboxylic acid is pptd. by the addn. of NaCl, and this is treated with NaOH and  $\text{NaHSO}_4$ , filtered and acidified and heated on the water bath until the hydroxythionaphthene is formed and this is transformed into 4,4'-dimethylbisthionaphthene indigo in known manner. 3-Methylbenzene-2-carboxy-1-thioglycolic acid (by transforming 6-chloro-*o*-toluidine into the CN compd. by way of the diazo compd., sapong. the CN group to  $\text{COOH}$  and substituting the Cl by  $\text{S.CH}_2\text{COOH}$  in the manner described in Ger. 189,200) may also be used as starting material. 4-Methyl-6-chloro-2,3-dihydro-3-keto-2-(*p*-dimethylaminophenylimino) thionaphthene is heated to boiling with 4-methyl-3-hydroxythionaphthene in glacial AcOH, yielding a dye which gives fast red shades on cotton. Dichloroisatin is heated in  $\text{C}_6\text{H}_6$  with  $\text{PCl}_5$  and 4-methyl-3-hydroxythionaphthene, yielding a dye which gives fast violet shades on cotton.

**Vat dye.** SOC. ANON. POUR L'IND. CHIM. À BALE. Swiss 130,074, Sept. 9, 1927. Addn. to Swiss 125,480. A vat dye is prepd. by sulfonating benzanthrone with fuming  $\text{H}_2\text{SO}_4$  at ordinary temps., treating the product with caustic alkali at  $250\text{--}310^\circ$ , and methylating. The dye colors cotton a fast gray-blue in a red-violet bath. Cf. C. A. 23, 2833.

**Vat dyes.** ERWIN HOFFA, HANS HEYNA, ERWIN THOMA and OTTO HIRSCHL (to Grasselli Dyestuff Corp.). U. S. 1,710,981, April 30. Indigoid dyes dyeing cotton fast red to bluish red tints are formed by oxidation (suitably with a soln. of  $\text{K}_2\text{FeC}_4\text{N}_6$  or with air in the presence of  $\text{CuSO}_4$ ) of hydroxynaphthenes prepd. from the 3,5-dialkyl-4-halogenphenyl-1-thioglycolic acids and from 3,4-dialkyl-5-halogenphenyl-1-thioglycolic acids and their derivs. which are substituted in the 2-position by the nitrile group,  $\text{CONH}_2$  or  $\text{COOH}$ . The dyes obtained may be further halogenated. Several examples are given.

**Derivatives of vat dyes.** DURAND & HUGUENIN A.-G., MARCEL BADER and CHARLES SUNDER (Wilhelm Bauer and Alfred Herre, inventors). Ger. 474,036, Oct. 27, 1925. Addn. to 424,981. Ger. 424,981 describes the manuf. of solid, stable, water-sol. derivs. of vat dyes by treating the corresponding leuco compds. with  $\text{HClSO}_3$ , while excluding  $\text{H}_2\text{O}$ . This method is now modified by using pyrosulfuryl chloride ( $\text{ClSO}_2\text{OSO}_2\text{Cl}$ ) instead of  $\text{HClSO}_3$ . The presence of a little  $\text{H}_2\text{O}$  is not harmful, since  $\text{H}_2\text{O}$  reacts with  $\text{ClSO}_2\text{OSO}_2\text{Cl}$  to give  $\text{HClSO}_3$ . Examples are given describing the manuf. of products from dibromoindigo white and the leuco compd. of 4,5',7'-trichloroindigo (prepd. by treating 5,7-dichloroisatin- $\alpha$ -chloride with monoacetyl-4-chloroindoxyl).

**Anthraquinone vat dye.** BRITISH DYESTUFFS CORP., LTD., and S. THORNLEY. Brit. 298,928, July 15, 1927. Vat dyes obtained by alkali fusion of sulfonic acids prepd. by direct sulfonation of homologs or derivs. of benzanthrone such as *Be*-1-chloro- and 2-methyl-benzanthrones are condensed with hydroxylamine or its salts with or without the use of  $\text{FeSO}_4$ ; vat dyes obtained by alkali fusion of the benzanthrone-sulfonic acids prepd. from anthraquinonesulfonic acids may be similarly treated. Dyes are produced giving bluish or grayish dyeings.

**Readily soluble vat color preparations.** WILHELM BAUER, ALFRED HERRE and ALBERT FUNKE (to Grasselli Dyestuff Corp.). U. S. 1,711,008, April 30. Di(*p*-chloroanilino)benzoquinone is treated with monople soap or other suitable dispersing agent and an alkali such as soda in the presence of water, and the mixt. is dried and mixed with a reducing agent such as hyposulfite which is capable of reducing the insol. vat color to its leuco form. U. S. 1,711,009 relates to similar products.

**Cloth-printing dyes.** I. G. FARBENIND. A.-G. (Martin Hankel, inventor). Ger. 474,659, Sept. 1, 1927. Pure nitrosoamine print dyes are prepd. by dissolving the components in the min. amt. of water and alkali, filtering, concg. or evapg. to dryness, and, if desired, adding more alkali. The components are thus brought to such concn. that, on mixing, no undesirable dye formation occurs. Thus, 100 kg.  $\beta$ -hydroxynaphthoaniline is dissolved in 300 kg. water and 110 kg. NaOH at  $60\text{--}80^\circ$  and filtered. Also, 200 kg. of a wet paste of the nitrosoamine Na salt of *o*-nitroaniline contg. 26.3% *o*-nitroaniline and 4% NaOH is dissolved in 200 kg. water at  $60^\circ$  and filtered. The two filtrates are poured together at  $30^\circ$  and evapd. *in vacuo*. Other examples are given.

**Benzanthrone dyes.** BRITISH DYESTUFFS CORP., LTD., J. BADDILEY, A. SHEP-

HERDSON and S. THORNLEY. Brit. 298,931, July 16, 1927. 2-Methylbenzanthrone or a chlorobenzanthrone or other simple homolog or substitution product of benzanthrone is sulfonated (preferably with oleum), with or without the use of catalysts such as Hg, and the sulfonic acids thus formed are subjected to alkali fusion to produce dyes of reddish blue color. Cf. C. A. 22, 3534.

**Benzanthrone dyes.** I. G. FARBENIND. A.-G. Brit. 298,583, May 12, 1927. The conversion products obtained by treating Bz-1-phenylbenzanthrones with  $\text{AlCl}_3$  (as described in Brit. 297,129; C. A. 23, 2579) are converted into vat dyes by melting them with a caustic alkali or other alk. condensing agent such as an alkali metal amide, anilide or alcoholate. An example is given of the production of a dye from Bz-1-phenylbenzanthrone which dyes cotton fast bluish green shades from a blue vat. Cf. C. A. 23, 991.

**Sulfur dyes.** SOC. ANON. POUR L'IND. CHIM. À BAËLE. Ger. 474,786, April 8, 1923. The leuco compd. of indophenol is sulfurized in the presence of benzidine. Thus, 27.2 parts indophenol, obtained by the condensation of nitrosophenol with carbazole, is melted and mixed with 29 parts powd.  $\text{Na}_2\text{S}$  and 36 parts powd. S. The mixt. is allowed to stand until the reduction of the indophenol is complete. It is then dried *in vacuo*, powd. and mixed with 9.2 parts benzidine. The product is baked at 180–190° until no further  $\text{H}_2\text{S}$  is evolved, after which it is cooled, ground up and extd. with  $\text{Na}_2\text{S}$  to remove the excess of S. The resulting S dye colors cotton an indigo-blue tone fast to washing, to light and to Cl. Other examples are given.

**Thiazoles; dyes.** COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUF. DE PRODUITS CHIM. DU NORD RÉUNIES, ÉTABLISSEMENT KUHLMANN. Fr. 648,405, June 23, 1927. Thiazoles of the formula

in which the 2nd benzene ring may be substituted, are obtained by treating, with BzCl or its derivs., an aminothiophenol obtained by nitrating 1,4-dichlorobenzene, converting this into dichlorodinitrophenylbisulfide and transforming the latter. By treating the aminothiophenol with *o*-, *m*- or *p*-nitrobenzoyl chloride, *o*-, *m*- or *p*-nitrothiazole is obtained which can be reduced with Sn or Fe, HCl and alc. to the corresponding aminothiazoles, which products or their sulfo derivs. or oxidized sulfo derivs. can be diazotized and coupled with known coupling agents to form valuable dyes for wool and silk. Fr. 648,406 describes a process in which aminothiophenols are obtained by the action of  $\text{S}_2\text{Cl}_2$  on *o*-toluidine, *p*-phenetidine, *o*-anisidine, *o*-chloraniline in accordance with Ger. 360,690, 367,344, 367,345, 367,346, 364,822 and 370,854, and the aminothiophenols are then treated with BzCl or its derivs. as in Fr. 648,405.

**Sulfonic acids.** I. G. FARBENIND. A.-G. (Arthur Lüttringhaus and Paul Nawiaskey, inventors). Ger. 472,925, Nov. 4, 1925. Sulfonic acids are prepd. from the hydro compds. of vat dyes by treating the condensation products of these compds. with halohydroxyalkyl compds. in the presence of chlorosulfonic acids or substances with an analogous action. Thus, pyridine is dropped into a chlorosulfonic acid, and the condensation product of glycol chlorohydrin and the hydro compd. of *N*-dihydro-1,2,1',2'-anthraquinoneazaine added. NaOH is added and the pyridine distd. off by steam. The product is washed and the filtrate salted out, giving a dye which colors wool red in an acid bath. Instead of pyridine, dimethylaniline may be used.

**Nitro-2-amino-1-benzoic acids.** I. G. FARBENIND. A.-G. Fr. 649,324, Feb. 20, 1928. Nitro-2-amino-1-benzoic acids and their alkyl, aryl or aralkyl derivs. in the amino group are prepd. by submitting 2-chloro-4(or 6)-nitro-1-benzoic acid to a reaction with  $\text{NH}_3$ , an alkylamine, an arylamine or aralkylamine in the presence of a catalyst. Thus, 4-nitro (or 6-nitro)-2-chloro-1-benzoic acid is heated under pressure to about 120° with  $\text{NH}_3$  soln. in the presence of finely divided Cu. The products, 4-nitro-(m. 279°) and 6-nitro-2-chloro-1-benzoic acid (m. 184–185°), are thus obtained cheaply and easily for the prepn. of dyes of various groups.

**2', 4'-Dichloro-*o*-benzoyl-benzoic acid.** IVAN GUBELMANN, HENRY J. WEILAND and OTTO STALLMANN (to Newport Co.). U. S. 1,711,144, April 30. This compd. forms white crystals, m. 100–101°. It may be used as a dye intermediate and may be made by condensing *m*-dichlorobenzene and phthalic anhydride.

**3'-Nitro-4',6'-dichloro-*o*-benzoyl-benzoic acid.** IVAN GUBELMANN, HENRY J. WEILAND and OTTO STALLMANN (to Newport Co.). U. S. 1,711,145, April 30. This compd. is made by treating 2',4'-dichloro-*o*-benzoylbenzoic acid in sulfuric acid mono-

hydrate at 10° with mixed nitrating acid and dilg. with cold water. It is a cryst. compd. m. 174° and suitable for use in making dyes.

**3'-Amino-4',6'-dichloro-*o*-benzoylbenzoic acid.** IVAN GUBELMANN, HENRY J. WEILAND and OTTO STALLMANN (to Newport Co.). U. S. 1,711,146, April 30. This compd. is made by reducing the corresponding nitro compd. with Fe and HOAc at 90–95°, rendering the reaction mass alk., filtering and acidifying. It m. 164° and may be used as a dye intermediate.

**Condensation products of the anthraquinone series.** GEORG KRÄNZLEIN and MARTIN CORELL (to Grasselli Dyestuff Corp.). U. S. 1,710,992, April 30. Compds. which may be used as *dye intermediates* or directly as *dyes for dyeing "acetate silk"* are formed by subjecting a compd. of the general formula  $\text{NH}_2\text{ASR}$ , in which A stands for an anthraquinone residue (which may be substituted) and R stands for H or an alkali metal, the  $\text{NH}_2$  and SR groups standing in *o*-position to each other and in an  $\alpha$ - and  $\beta$ -position, and, when R represents H, in the presence of an acid-binding substance, to reaction with compds. of the general formula  $\text{Hlg. CH}_2\text{CH}_2\text{X}$ , in which Hlg stands for halogen and X for a halogen or OH. Examples are given of the production of 1-aminoanthraquinone-2-( $\omega$ -hydroxy)-ethylthio ether, m. 171–3°, 1-aminoanthraquinone-2-( $\omega$ -bromo)-ethylthio ether, m. 145–7°, 1-amino-4-(*p*-tolyl)-aminoanthraquinone-2-( $\omega$ -bromo)-ethylthio ether and some similar compds.

**Dyes and intermediates.** COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUF. DEP. PRODUITS CHIM. DU NORD RÉUNIS, ÉTABLISSEMENTS KUHLMANN. Fr. 650,086, Aug. 5, 1927. **4-Chloro-6-sulfo***benzenediazo oxide* of the formula

is obtained by the action of NaOAc on diazotized 2-nitro-4-chloro-6-sulfo-1-amino-benzene. This product couples with azo components to give mordant dyes dyeing wool directly in an acid bath which may be after-chromed or coppered. They yield metal compds. when treated in substance with metallic salts, *e. g.*, Cr salts. Examples of azo components are: resorcinol, 1-(4'-sulfophenyl)-5-pyrazolone-3-carboxylic acid, 1-(4'-sulfophenyl)- and phenyl-3-methyl-5-pyrazolone,  $\alpha$ - and  $\beta$ -naphthol and acetoacetanilide. The prepn. of sol. Cr compds. is also given. Cf. C. A. 23, 714.

**Dyes and intermediates.** I. G. FARBENIND. A.-G. Brit. 298,493, Oct. 8, 1927. Alkoxy-3-hydroxythionaphthenes are made by treating an alkoxyarylthioglycolyl halide of the benzene or naphthalene series (such as 1-methyl-6-chloro-4-methoxybenzene-3-thioglycolyl chloride or 6-ethoxynaphthalene-2-thioglycolyl chloride—prepd. from the acids by the action of  $\text{SOCl}_2$  and  $\text{PCl}_5$ , resp., in  $\text{PhCl}$  soln.) with an Al halide such as  $\text{AlCl}_3$ , preferably in the presence of a solvent which may be that used in forming the halide employed as starting material. 6-Ethoxynaphthalene-2-thioglycolic acid is prepd. by reducing 6-ethoxynaphthalene-2-sulfonyl chloride to the mercaptan and condensing with chloroacetic acid. 4-Ethoxynaphthalene-1-thioglycolic acid, 7-methoxynaphthalene-1-thioglycolic acid, 4-ethoxynaphthalene-2-thioglycolic acid and 7-methoxynaphthalene-2-thioglycolic acid may also be used as starting materials.

**Dyes and intermediates.** I. G. FARBENIND. A.-G. Brit. 298,775, Oct. 21, 1927. Pyrazoleanthrone derivs. are formed by reaction of pyrazoleanthrone, or substitution derivs., with nuclear halogenated aromatic compds. of the benzene, naphthalene or anthracene series, with or without use of a diluent, catalyst or acid-binding substance. Among the starting materials which may be used are: bromobenzene, *o*-bromo- (or chloro)benzoic acid, *Bs*-1-bromobenzanthrone (or its nitrated deriv.),  $\alpha$ -chloroanthraquinone, 1,5-dichloro-2,4-dinitrobenzene, 2-chloro-3-naphthoic acid,  $\alpha$ -bromonaphthalene, *o*-chloronitrobenzene and similar compds. V salts may be used as catalysts and pressure may be employed. *Bs*-1-chloro-*Bs*-2-phenylbenzanthrone (one of the starting materials mentioned) is made by substituting  $\text{NH}_2$  for OH in *Bs*-1-hydroxy-*Bs*-2-phenylbenzanthrone, diazotizing and replacing the diazo group by Cl by the Sandmeyer method.

**Dye intermediates.** I. G. FARBENIND. A.-G. Brit. 298,955, Oct. 17, 1927. Oxythionaphthenes are prepd. from thioglycolic acids of the benzene series having a CN,  $\text{COOH}$  or  $\text{COO-metal}$  group in the 2-position, an alkyl group in the 3-position and which may have a halogen atom or an alkyl group in the 4-, 5- and 6-position, by merely heating with water under pressure. The products are washed with  $\text{Na}_2\text{CO}_3$ , dissolved in alc. NaOH and reprecipitated with HCl. Examples are given of the treatment of: 3-

methyl-5-chlorophenyl-1-thioglycolic-2-carboxylic acid, 3,6-dimethyl-5-chlorophenyl-1-thioglycolic-2-carboxylic acid, 2-cyano-3-methyl-5-chlorophenylthioglycolic and 2-cyano-3,6-dimethyl-5-chlorophenylthioglycolic acid.

**Dye intermediates.** I. G. FARBENIND. A.-G. (Karl Schirmacher, Wilhelm Schaich and Karl Eishold, inventors). Ger. 473,471, Nov. 4, 1926. Anthrahydroquinone-9,10-disulfuric acid esters or their salts are prepd. by treating anthraquinone or such substitution products thereof as are not vat dyes with a halogen sulfonic acid, or an ester or salt of such acid, and a metal in the presence of a tertiary base. According to example 1, anthraquinone (20.8 parts) is added to a cooled mixt. of pyridine (200 parts) and  $\text{HClSO}_3$  (50 parts) or  $\text{MeClSO}_3$  (56 parts), and after stirring the temp. is allowed to rise to  $65^\circ$ , when Cu bronze (30 parts) is gradually added. The mixt. is cooled to  $30$ – $35^\circ$  and poured into NaOH soln. The pyridine is removed by steam distn. and the residue filtered and concd. The di-Na salt of anthrahydroquinone-9,10-disulfuric acid ester crystallizes out. Other examples, conducted similarly, describe the manuf. of products from  $\beta$ -acetaminoanthraquinone,  $\beta$ -formylaminoanthraquinone,  $\beta$ -aceto-hydroxyanthraquinone and 2,6-diacetaminoanthraquinone; the Ac or formyl group is split off during the reaction.

**Lakes.** I. G. FARBENIND. A.-G. (Leo Rudolf and Bodo Zschimmer, inventors). Ger. 474,381, July 23, 1925. Lakes are prepd. from the condensation products obtained by the interaction of a halogenated aromatic compd. contg. nitro or quinone groups with an aromatic amine. The amine may contain substituents such as  $\text{HSO}_3$ ,  $\text{COOH}$  or  $\text{OH}$ . Examples are given corresponding to those in Brit. 274,627 (C. A. 22, 2278).

**Dyeing.** I. G. FARBENIND. A.-G. Brit. 299,069, Oct. 20, 1927. Fast dyeings and prints are produced by applying an alkali soln. of an arylthioglycolic- $\alpha$ -carboxylic acid amide (such as a bath formed with NaOH and 5-chloro-1-methylbenzene-3-thioglycolic-2-carboxylic acid amide), drying if necessary, steaming and oxidizing as with  $\text{K}_3\text{FeC}_6\text{N}_6$  or bleaching powder. Various details and examples are given.

**Dyeing.** SOC. ANON. POUR L'IND. CHIM. À BÂLE. Swiss 130,406. Previously dyed delicate animal filaments such as down and fur are discharged by Zn aldehydesulfoxylate in the presence of an acid. Thus, down previously dyed, and dischargeable with a hydrosulfite prepn., is treated with basic Zn formaldehydesulfoxylate, gum and tartaric acid.

**Dyeing artificial silk.** BRITISH DYESTUFFS CORP., LTD., JAMES BADDILEY, PERCY CHORLEY and CARLTON BUTLER. Ger. 474,430, Mar. 4, 1927. See Brit. 276,450 (C. A. 22, 2471).

**Dyeing artificial silk.** I. G. FARBENIND. A.-G. (Rudolf M. Heidenreich, inventor). Ger. 473,454, Sept. 25, 1925. Fast shades are obtained in dyeing cellulose ester or ether silk with aminoanthraquinones or their derivs. when the dyeing is performed in the presence of a sulfurized phenol. An example is given.

**Dyeing cellulose acetate, etc.** BRITISH CELANESE, LTD., G. H. ELLIS and H. C. OLFIN. Brit. 298,699, July 19, 1927. Dyeing, printing or stencilling is effected by oxidation of one or more amines on the material by the action of a chloramide. Numerous details and examples are given. 4-Chloro-2-amino-4'-ethoxydiphenylamine (one of the starting materials used) is made by reduction of the nitro compd. obtained from 2,5-dichloronitrobenzene and *p*-phenetidine.

**Dyeing cellulose acetate and other cellulose derivatives.** BRITISH CELANESE, LTD., G. H. ELLIS, H. C. OLFIN and E. W. KIRK. Brit. 298,993, July 19, 1927. Dyeing, printing or stencilling is effected by the application of unsulfonated azo dyes obtained from aminonaphthols or their nuclear substitution products and having the azo group linked to the naphthalene nucleus in a position ortho or peri to an auxochromic group, such as (1) the dye obtained from aniline and 1,8-aminonaphthol, solubilized by Na ricinoleate; (2) the dye *p*-aminobenzene-azo-1,8-aminonaphthol, suitably solubilized by a dispersing agent, further diazotized on the fiber and coupled with 2,3-hydroxynaphthoic acid; or (3) the dye formed from dianisidine and 2 mols. of 1,8-aminonaphthol developed with a soln. of *p*-nitrobenzenediazonium acetate. These three dyes produce red, black and dark brown dyeings, resp. Dyes of various other similar specified groups also may be used.

**Facilitating dyeing of hydrated cellulose, etc.** I. G. FARBENIND. A.-G. Brit. 298,491, Oct. 6, 1927. Treatment of hydrated cellulose to reduce its tendency to swell as described in Brit. 278,684 (C. A. 22, 2663) is carried out in the presence of an "indifferent" water-sol. salt such as NaCl and a mordant may also be used simultaneously or in a preceding treatment. Use of  $\text{CH}_3\text{O}$ , urea,  $\text{NH}_3$  and NaCl in the treatment of hydrated cellulose such as artificial silk is described. Dyeing may be further facilitated by subjecting the material to a final feeble bleach.

**Dyeing and printing mixed fabrics.** ALFRED THAUSS and ALFRED GUENTHER (to Grasselli Dyestuff Corp.). U. S. 1,711,002, April 30. In dyeing or printing mixed fabrics contg. animal fibers with dyes to be employed in acid or neutral baths, a sulfonation product such as may be obtained from resins (suitably "colophony sulfonic acid") is used for reducing or preventing absorption of dyes by wool and silk.

**Apparatus for dyeing, especially hanks of yarn.** HANS WAGNER. Ger. 473,609, Mar. 18, 1927.

**Dyeing machine for textile goods, especially hanks of yarn.** ROBERT HAMPE. Ger. 473,610, Mar. 20, 1926. The dye liquid can be transferred from vat to vat.

**Material printing.** CANTASILVA, G. M. B. H. Ger. 472,957, Nov. 29, 1927. Material is sized, or rubberized on one side only and printed on the opposite side.

**Printing woolen fabrics with ester salts of leuco compounds of vat dyes.** I. G. FARBENIND. A.-G. Brit. 298,648, Oct. 13, 1927. The goods are developed, after printing and steaming, with a soln. contg. a persulfate and a free acid. Examples are given.

**Textiles.** C. H. BOEHRINGER SOHN. Ger. 472,604, Dec. 28, 1927. Cotton and artificial silk are given a crackling feel by treating with a bath of soap and org. acid. A preferable mixt. is soap and lactic and tartaric acids, the latter being present in quantities between 5 and 50%.

**Flexible fabric coated with cellulose ester composition.** G. A. LANGVERTE ET CIE. Brit. 298,982, Oct. 18, 1927. A material suitable for automobile upholstery comprises a base of heavy closely woven fabric coated with a thick layer of a nitrocellulose or cellulose acetate compn. which may weigh 400–800 g. per sq. meter if desired. An app. and mech. details of coating are described.

**Treating fabrics of cellulose derivatives to render them more susceptible to ironing.** H. PLATT and C. M. CROFT (to British Celanese, Ltd.). Brit. 299,058, Oct. 21, 1927. Fabrics formed of, or contg., thermoplastic materials, such as cellulose acetate, formate, butyrate or propionate or methyl, ethyl or benzyl cellulose, are treated with an aq. soln. of an Al salt such as a soln. formed of basic Al acetate, together with HOAc or  $\text{NH}_4\text{CNS}$  to enable the fabric to be ironed without sticking to the iron. The treatment also serves to waterproof the fabric.

**Fibers from viscose or like materials.** I. G. FARBENIND. A.-G. Brit. 298,492, Oct. 7, 1927. In prepg. lustrous wool-like fibers by a process in which the material before cutting is treated with liquids, drained and centrifuged, the parallel character of the original winding and a practically uniform length and quality of fiber are obtained by winding the threads from the nozzle onto hollow perforated drums of metal, ceramic ware or other material which is chemically stable. Various details of an app. used and of procedure are described.

**Treatment of fibers.** I. G. FARBENIND. A.-G. Ger. 474,557, Feb. 22, 1927. Cloth fibers, animal or vegetable, are treated with halogenizing or oxidizing agents after treatment with org. sulfo acids or their salts. Thus, 50 kg. worsted goods are treated for 10 minutes with 1000 l. of water contg. 1 g. active Cl and 4 g. chlorinated isopropyl naphthalenesulfonic acid per l. This gives the goods an improved gloss and touch. Other examples are given.

**Liquefaction of silk.** KANEGAFUCHI BOSEKI KABUSHIKI KWAISHA. Fr. 649,979, Feb. 28, 1928. A colloidal soln. of crude natural silk or waste silk threads is made by means of a soln. of  $\text{Mg}(\text{NO}_3)_2$  or other sol. salt of Mg, and the Mg salt is sepd. The product may be used for making threads or plastic materials. Fr. 649,980 describes a process for spinning the liquefied silk.

**Artificial silk.** FRANZ J. GAHLERT. Ger. 472,113, June 10, 1925. See U. S. 1,666,090 (C. A. 22, 2056).

**Artificial silk, films, etc.** COURTAULDS, LTD. Fr. 648,704, Feb. 13, 1928. Centrifuges for the treatment of cakes of artificial silk with washing, dyeing or soaping liquids are described.

**Treating artificial silk or other threads with liquids while wound on a perforated drum.** M. SCHOENFELD. Brit. 298,721, Aug. 5, 1927. An app. is described which is provided with devices which project through the drum to lift the threads from the surface of the drum as the latter revolves and thus facilitate penetration of the treating liquid.

**Device for straining skeins of artificial silk.** OTTO SINDL (to the Firm Nuera Art-Silk Co., Ltd.). U. S. 1,711,465, April 30. Structural features are described of a device suitable for handling "viscose silk" skeins.

**Washing artificial silk.** HERMINGHAUS & Co., G. M. B. H. Ger. 474,442, Sept. 23, 1927. Addn. to 464,016. According to Ger. 464,016, artificial silk and like cellulosic products are washed while wound on perforated or imperforated bobbins coated with a

water-sol. layer, the soln. of which allows the fibers to swell. This method is now applied with bobbins which, besides having a water-sol. layer, are porous or provided in addn. with a porous layer. Cf. C. A. 23, 2569.

**Washing textiles.** THE DE LAVAL SEPARATOR Co. Ger. 473,807, May 13, 1925. Washing liquids, such as  $C_6H_6$ , from dyed textile fabrics and the like, are purified and decolorized by an app. which pumps the liquid through a filter and a decolorizing agent.

**Damping agent.** CHEMISCHE FABRIK VORM. SANDOZ. Swiss 130,604, June 1, 1927. Addn. to Swiss 128,440 (C. A. 23, 2837). A penetrating moistening agent for textiles and similar goods is formed by mixing a phenol with hydrogenated naphthalene. Thus, 92 kg. crude cresol and 8 kg. tetrahydronaphthalene form a suitable mixt.

**Wetting agents.** H. T. BÖHME A.-G. Brit. 298,559, Oct. 11, 1927. Products suitable for use in the *textile* and *leather industries* as wetting, cleaning and emulsifying agents, and which appear to be true sulfonic acids, are formed by treating aliphatic acids of high mol. wt. such as oleic acid or linoleic acid with  $H_2SO_4$  in the presence of org. acid anhydrides or chlorides such as  $Ac_2O$  or acetyl chloride. The alkali salts of the sulfoacids may be dried without loss of their wetting properties, etc. The alk. earth metal salts are sol. and the products may be used with hard water.

**Wetting agents.** H. T. BÖHME A.-G. Brit. 298,560, Oct. 11, 1927. An aromatic sulfoacid, preferably having an aliphatic side chain of at least 3 C atoms, such as dipropyl-naphthalenesulfoacid, is mixed with a product formed by treating a higher unsatd. aliphatic acid such as oleic acid with  $H_2SO_4$  in the presence of aromatic acid chlorides or anhydrides. Hydrocarbons and halogenated hydrocarbons may also be added. The product serves both as a wetting and softening agent for *textile materials*. Cf. C. A. 23, 1228.

**Apparatus for the wet treatment of open-width fabrics in endless lengths.** ZITTAUER MASCHINENFABRIK A.-G. Ger. 473,466, May 13, 1927.

**Apparatus for the wet-treatment of goods, especially dyeing hat shapes.** SOC. DES CONDENSEURS DELAS. Ger. 473,608, Oct. 14, 1927.

**Bleaching.** I. G. FARBENIND. A.-G. (Helmuth Korte, inventor). Ger. 473,869, Nov. 20, 1925. Wool and wool mixts. are bleached by treating with acidified hypochlorite lye contg. a permanganate.

**Mercerizing.** HECTOR LOBRY. Fr. 648,413, June 24, 1927. Cotton goods, particularly when knitted, are placed on forms without tension and put between fine metallic gratings and plunged into the mercerizing bath above which a vacuum has been created.

**Mercerizing cotton.** CAMILLE BUREL. Fr. 649,889, July 29, 1927. The cotton is first boiled in an autoclave under pressure, dried and but into the mercerizing bath, over which a high vacuum is created, and finally air under pressure is introduced.

**Apparatus for drying and steaming tubular fabrics.** MAURICE M. KASANOF. U. S. 1,711,094, April 30.

**Treating oil-soaked hemp waste.** CHANNING C. BEETH. U. S. 1,710,914, April 30. The waste is soaked in a soln. of NaOH and live steam is passed through the material to cook it, the liquid is removed, and the product is pressed into sheets, such as *fiber-board*.

**"Mothproofing" wool, fur, etc.** I. G. FARBENIND. A.-G. Brit. 299,055, Oct. 20, 1927. The material is treated with a cold aq. soln. of a non-halogenated non-sulfonated hydroxycarboxylic acid or a substitution product such as 2-hydroxybenzoic acid, methylhydroxybenzoic acid or resorcylic acid, and an org. or inorg. acid or salt may also be added.

**Protecting wool, fur or hair from insects.** I. G. FARBENIND. A.-G. Brit. 298,538, Oct. 10, 1927. The material is treated with a complex compd. of B fluoride with an org. acid such as HOAc. Water or org. solvents such as alc. or acetone may be used as solvents or diluents and wet treatment may be carried out in the dye bath or by steeping or spraying or dry treatment may be carried out in the fulling vessel. K borofluoroacetate may be used and mention is also made of the use of compds. of B chloride with org. acids.

## 26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

**Prussian blue and titanium white in light.** GEORG ZERR. *Farben-Ztg.* 34, 1430-1 (1929).—After 35 days' exposure the color of paints prepd. from linseed-oil varnish and the following pigments tinted with Prussian blue were:  $ZnO$ , slightly reddish;

lithopone, slightly greenish; titanium white, considerably bleached; white lead, slightly greenish. The effect of titanium white cannot be explained by the presence of  $H_2SO_4$  for lithopone which may develop acid on weathering does not bleach Prussian blue.

G. G. SWARD

**Systematic classification of adhesives and vehicles.** HANS WAGNER. *Farben-Ztg.* 34, 1430(1929); cf. C. A. 23, 2840.—W. modifies the previous arrangement as follows: (1) mobile at room temp. (viscous systems); (2) immobile at room temp. but, *a*, becoming so at slight pressures, *e. g.*, stirring (plastogels), *b*, mobile at slight elevation of temp. slightly elastic (normal gels), *c*, those which offer considerable resistance to change of form (elastogels).

G. G. SWARD

**The manufacture of oil for lead whites.** H. HELLER. *Farben-Ztg.* 34, 506(1928).—This is a brief review on the refining of linseed oil by means of  $H_2SO_4$  for use in white lead paints.

G. G. SWARD

**The Florida tung-oil project.** B. F. WILLIAMSON. *Ind. Eng. Chem., News Ed.* 7, No. 9, 5-6(1929).

E. H.

**East Indian copals and damars.** A. F. SUTER. *J. Roy. Soc. Arts* 77, 577-98 (1929).

E. H.

**Copal melting; obtaining copals in easily soluble forms.** EWALD PYHÄLÄ. *Farben-Ztg.* 34, 1552-3(1929).—Powdered Zanzibar copal mixed with 20-30% mineral oil, the b. p. of which was higher than the m. p. of the copal, was melted in an enameled vessel. To avoid local overheating a metallic Zn bath was used. The fusion was continued until the mineral oil was evapd. The losses ranged from 12.7 to 31.2%. The product was comparable in color to W rosin, was sol. in turpentine, benzine, etc. Varnishes can be prepd. by the addn. of hot previously bodied oils to the molten resin or by mixing solns. of the resins with such oils.

G. G. SWARD

**Colorimetric determination of turpentine vapors in air** (ANDREEV, GAVRILOV) 7. Sulfonated tar (U. S. 1,711,448) 21. Coating compositions (Fr. pat. 649,782) 18. Oxide mixtures [for pigments] (Ger. pat. 474,416) 18.

**Paint.** WALTER ENGEL. Ger. 474,917, Mar. 24, 1927. Paint and similar viscous and inflammable materials are satd. with  $CO_2$  under pressure to render them non-inflammable and to enable them to be obtained as a jet from a container.

**Paint composition.** HOWARD W. MATHESON (to Can. Electro Products Co.). Can. 288,642, April 9, 1929. A compn. of matter for lacquer, varnish, enamel or paint includes a product resulting from the treatment of a vinyl ester with an aldehyde, a volatile solvent therefore, and a varnish resin or gum.

**Water-paints.** A. KNAPP. Brit. 298,843, Feb. 24, 1928. A paste of pigment, glue and water is mixed with an emulsion of linseed oil or other drying oil and  $NH_4$  resinate in aq. soln.

**Nitrocellulose paints, etc.** R. T. HUCKS (to Imperial Chemical Industries, Ltd.). Brit. 298,914, Oct. 15, 1927. Pulp pigments or the like (of which various examples are given) contg. water are mixed with a nitrocellulose plastic contg. a substance miscible with nitrocellulose but immiscible with water, so that the water seps. and may be removed. The sepn. of the water may be hastened by addn., during the mixing, of an active nitrocellulose solvent such as EtOAc, BuOAc, AmOAc or similar solvents. The products may be used for forming sheets or in solns. as coating compns.

**Preparation of white lithopone by means of incompletely purified zinc solutions.** M. BIDAINE. Belg. 353,936, Oct. 31, 1928. The yellowish or reddish yellow tint of impure lithopone is counteracted by addn. of blue or blue-green coloring matter.

**Drying oil and oil varnish coating compositions.** J. SCHREIBER (to Chemische Fabriken Dr. J. Wiernik & Co. A.-G. and Bakelite Ges.). Brit. 299,024, Oct. 19, 1927. The durability of coatings having a basis of drying oil or oil varnish is improved by treating them, after the usual drying, with deoxidizing substances such as multi-valent phenols or  $\alpha$ -naphthol or their mixts. in a volatile solvent which softens but does not dissolve the coating, *e. g.*, solvent naphtha. Urea derivs. also may be used and a small proportion of wood oil with or without stand oil may be added to maintain the surface gloss of the coating.

**Varnish.** SCHERING-KAHLBAUM A.-G., ERICH FREUND and HANS JORDAN. Ger. 474,683, Aug. 23, 1922. Lacs and varnishes are prepd. by dissolving the resinous mass obtained by adding 0.5%  $Fe_2O_3$  to chlorinated naphthalene, as described in Ger. 466,262 (C. A. 23, 1000) in  $CCl_4$  or acetone.

**Varnish for shoes.** COURT BROMA. Swiss 130,137, Sept. 14, 1928. A prepn. for

varnishing shoes comprises 60 parts of a solvent b. 80–90°, such as amyl or butyl acetate, 7 parts of a softening material such as tricresylphosphate, 5 parts of pyroxylin and 0.5–2 parts of dye.

**Polymerized vinyl acetate.** WILLY O. HERRMANN and WOLFRAM HÄHNEL (to Consortium für elektrochemische Industrie). U. S. 1,710,825, April 30. Vinyl acetate is polymerized in EtOH (suitably by heating with benzoyl peroxide) to form a compn. which is sol. in alc. and suitable for use as a lacquer.

**Ornamental coatings on wood, metal or other surfaces.** LEO L. SIMON. U. S. 1,711,330, April 30. Crackle enamel is placed over a multi-colored design (which may be formed with a metal paint) with an intervening layer of binder material, such as transparent varnish or lacquer.

**Molding composition.** HOWARD W. MATHESON (to The Can. Electro Products Co., Ltd.). Can. 288,641, April 9, 1929. Reaction products result from the treatment of vinyl esters with aldehydes, particularly those resulting from the treatment of vinyl acetate with acetaldehyde, and are useful as substitutes for shellac and other resinous binders.

**Esters of resin acids.** A. C. JOHNSTON. Brit. 298,972, Oct. 18, 1927. A resin acid such as abietic acid or a resin such as wood rosin or a resin contg. pimaric acid is treated with an alkyl halide such as EtCl, AmCl, EtBr or BuBr in the presence of an alkali, such as NaOH, KOH, Ca(OH)<sub>2</sub>, or Na<sub>2</sub>CO<sub>3</sub>, preferably in soln. in alc. Various details and examples are given.

**Resin.** CHEM. FABRIK KURT ALBERT, G. M. B. H. Ger. 474,787, Feb. 15, 1923. Addn. to Ger. 440,003. Natural resins are improved by adding phenol-alc. compds instead of phenolaldehyde condensation products. Thus, 100 parts colophony are heated with 10 parts *p*-cresol-dialc. for 10 hours at 80–90°. The m. p. of the mixt. rises gradually from 60–70° to 100–110°. Other examples are given.

**Resinous compositions.** I. G. FARBENIND. A.-G. (Arthur Voss, inventor). Ger. 473,411, Jan. 9, 1926. The products obtained by energetic oxidation of natural resins such as colophony are condensed with aldehydes in the presence of alkali. The condensation products, either as such or after esterification with glycerol, phenol, carbohydrates, etc., are suitable for use in varnishes, etc. In one example, colophony is oxidized with O under pressure and the oxidation product is treated with CH<sub>2</sub>O and NaOH. The condensation product is sepd. by acidification. Other examples are given describing condensation with AcH and BzH.

**Resinous products.** P. KRISHNAMURTHY. Brit. 298,939, Oct. 17, 1927. Benzyl chloride is formed by chlorinating toluene in the presence of sunlight or of a catalyst, the purified product is dissolved in CS<sub>2</sub>, a small proportion of ZrCl<sub>4</sub> is added, HCl is evolved, and a reddish brown liquid is formed which is mixed with water and treated with steam to remove CS<sub>2</sub>, boiled with water and dried. A yellow solid product is thus obtained which is powdered, extd. repeatedly with C<sub>6</sub>H<sub>6</sub> or coal-tar naphtha, the clear soln. is evapd. and the residue heated to 260°. It may be used as a substitute for shellac and may be mixed with a condensation product obtained from the same starting material by the action of AlCl<sub>3</sub> or may be mixed with rubber, gutta-percha or similar materials. FeCl<sub>3</sub> may be used instead of Zr chloride but in that case the Fe should be removed from the product by repeated treatment with acids.

**Condensation products of aromatic amines and formaldehyde.** I. G. FARBENIND. A.-G. (Willi Hildebrand, inventor). Ger. 472,824, May 18, 1926. Addn. to Ger. 453,276. Resin-like condensation products of aromatic amines and CH<sub>2</sub>O are produced by preheating the alc. amino soln. and the acidified CH<sub>2</sub>O and allowing them to react. The exothermic production of the resinous mass maintains the high temp. of the reaction mixt. Thus, 100 kg. *o*-toluidine and 70 kg. 94% alc. are heated to boiling in a reflux condenser and 115 kg. 30% CH<sub>2</sub>O with 0.4 kg. HCOOH added. After a short time, the heat generated by the reaction is sufficient to maintain the temp. of the reagents. A bright yellow resin which softens at 80–85° is produced.

**Condensation products of phenols and carbonyl compounds.** CHEM. FABRIK KURT ALBERT, G. M. B. H. Ger. 474,561, Feb. 26, 1925. Ester-like derivs. of the condensation products of phenols and carbonyl compds. are prepd. by esterifying those products which contain free phenolic and alc. OH groups and which are not readily melted. The alc. OH groups may be directly esterified by high mol. org. acids with resulting production of acid resins. Thus, cresol-dialcohol is heated with linoleic acid at 180–200° for some time. At this temp. the escape of water can be clearly observed, giving an indication of the course of the esterification. The product may be distd. *in vacuo* or esterified with glycerol, glycol or other alcs.

**Condensation products of phenols and formaldehyde.** BAKELITE, G. M. H.

(Fritz Seebach, inventor). Ger. 474,729, June 17, 1925. The crude resinous products are purified by heating with aq. alk. solns., such as lime water, Na lye or  $\text{NH}_4\text{OH}$ .

**Synthetic gummy or resinous materials.** HOWARD W. MATHESON and FREDERICK W. SKIRROW (to The Can. Electro Products Co., Ltd.). Can. 288,644, April 9, 1929. A compd. contg. an ethylene linkage is heated under pressure with a satd. aliphatic aldehyde in the presence of oxygen.

**Artificial resins.** ROBERT ARNOT. Fr. 648,906, Jan. 13, 1928. See Brit. 290,327 (C. A. 23, 1002).

**Artificial resins.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 649,657, Feb. 24, 1928. Synthetic resins such as obtained from polyhydric alcs. and polybasic acids are hardened by heating the fusible resin at 220–300°, then at 170–200° or for a longer time at 135–170°, the product being molded under pressure at 120–170°. The heating prior to molding may be 1st at 170–200°, or for a longer time at 135–170° and then at 220–300°. Molds of Al or stainless steel or lined with vitreous enamel are preferred. Cf. C. A. 23, 293.

**Synthetic resins.** I. G. FARBERNIND. A.-G. (Arthur Voss, inventor). Ger. 473,171, Sept. 30, 1927. The products obtained by condensing phenolaldehyde resins with halogen fatty acids are themselves condensed with polyhydric alcs., *e. g.*, glycol, glycerol, polyvinyl alc. and water-sol. carbohydrates. An example is given in which an alk. soln. of a condensation product from tricresol and  $\text{CH}_2\text{O}$  is treated with  $\text{ClCH}_2\text{COONa}$ . The resinous product is pptd. by acidification and is then condensed with glycerol, yielding a resin which becomes insol. and infusible but remains elastic when heated to 150–170°. In another example, a product from  $\text{PhOH}$ ,  $\text{CH}_2\text{O}$ , and  $\text{ClCH}_2\text{COOH}$  is condensed with polyvinyl alc. Cf. C. A. 23, 2309.

**Synthetic resins.** W. H. MOSS (to British Celanese, Ltd.). Brit. 299,065, Oct. 21, 1927. One mol. of a phenol-ketone condensation product is further condensed with less than 2 mols. of an aldehyde. An example is given of the heating of diphenylol-propane with an equimol. or slightly greater proportion of  $\text{CH}_2\text{O}$  to above 100° with a catalyst such as  $\text{H}_3\text{PO}_4$ , washing the lower layer which seps., with water or  $\text{Na}_2\text{CO}_3$  soln. (with or without various other addns.), and subjecting to steam or vacuum distn. to remove impurities, followed by final washing and melting and heating to 180–200°. The product thus formed, m. 140–50°.  $\text{H}_3\text{BO}_3$ ,  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  may be used instead of  $\text{H}_3\text{PO}_4$ , and other starting materials may be used such as those derived from ethyl-methyl ketone or diethyl ketone and cresol. The products are suitable for use in cellulose ester lacquers and plastic compns. Brit. 299,066 specifies the production of phenol-ketone resins by condensing a ketone such as acetone or Me-Et or di-Et ketone with a phenol-ketone such as diphenylol-propane, to produce a fusible, sol. resinous product suitable for use in lacquers with various cellulose esters or ethers or for making plastic compns. Brit. 299,067 specifies production of phenol-ketone-aldehyde resins by condensing a phenol-ketone resin such as diphenylol-propane-acetone resin with an aldehyde such as  $\text{CH}_2\text{O}$  (suitably by heating in the presence of an acid).

**Coating surfaces with synthetic resins, cellulose derivatives, etc.** W. H. MOSS (to British Celanese, Ltd.). Brit. 298,616, Oct. 12, 1927. Surfaces such as iron, glass or wood are coated, preferably with a compn. contg. a synthetic resin and which may also contain an org. cellulose deriv. such as a cellulose ether, and are then further coated with a cellulose ester or ether compn. Resins, dyes, pigments, oils, etc., also may be used in various compns. of which examples are given.

## 27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

**Observations on the examination of fatty substances under the Wood light.** A. G. NASINI AND P. DE CORI. *Ann. chim. applicata* 19, 46–54 (1929).—Olive oils, virgin as well as refined, were examd. under the Wood light. Refined oils show a blue fluorescence whereas, the virgin oils all show orange to red. Chlorophyll in EtOH as well as in refined oil soln. also shows red fluorescence, so that this substance may be added as an adulterant to a refined oil, to imitate a virgin oil. The Wood light, therefore, is not reliable under these conditions. Cholesterol from various sources was found to give fluorescence, but the pure compound is opaque to the light, so that the fluorescence is due to some impurity.

**The total fat determination in sulfonated oils.** H. POMERANZ. *Seifensieder-Ztg.* 56, 95–6 (1929).—A discussion on the evaluation of Turkey-red oils for total fat, org. SO<sub>3</sub>, hydroxy acids and stability toward Ca and Mg.

A. W. CONTIERI

P. ESCHER

**Researches on fats of birds of Japan. I.** RYOSEI KOYAMA. *J. Soc. Chem. Ind. (Japan)* 31, 292-6(1928); Suppl. Binding 31, 72-3(1928).—K. studied the fats obtained from Daurian tern (*Sterna longipennis*, Nordmann), Japanese snipe (*Gallinago mibuto*, Koyama), and Javan buzzard (*Bulastur indicus*, Gmelin). These specimens were treated separately according as they were male or female, and chickens or grown. These fats were yellow or pale brownish white in color, and m. 29.8-41.9°,  $d_{40}$  0.887-0.912,  $n_D^{20}$  1.464-1.471, sapon. values 179-196, acid values 0.08-2.67, I values 61-103, unsaponifiable matter 0.53-7.94%, and insol. Br compds. 1.88-31.08%, the Br contents of which ranged from 52.51 to 71.53%. Conclusion: The fats of these birds contained some higher unsatd. fatty acids. The satd. fatty acids of the fats seemed to be chiefly palmitic and stearic acids. The quantity of higher unsatd. fatty acids seemed to increase with the growth of the birds. The properties of the fats of the birds varied over their breeding season. Y. NAGAI

**The heat consumption in the stearin industry.** K. E. SKÄRBLÖM. *Tek. Tid. Uppf. C (Kemi)* 58, 73-5(1928).—In a factory working with the Twitchell method the heat consumption has been calcd. per 100 kg. raw fat: Coal burned in the steam boiler plant amounted to 607,200 cal.; 425,300 of this accompanied the steam, giving a loss of 181,900 in the fire-boxes. Coal burned in the fire-boxes of the fatty acid distn. plant amounted to 105,900 cal.; 24,200 of this was absorbed by the fatty acids, loss 81,700. Coal burned in the fire-boxes of the glycerol distn. plant amounted to 16,150 cal. Since the feed water for the steam boilers was preheated from 0° to 60° by means of waste steam the total heat absorbed by the steam was 425,300 + 40,000 = 465,300 cal. These were distributed in the different departments of the factory in the following proportions, calcd. per 100 kg. raw fat: Melting and purification 20,900 cal., second purification and decompn. 73,000, treating of the impure fat 4000, extn of the impure fat 9100, distn. of fatty acids 68,500, acidification 45,600, refining of glycerol water 7000, cong. the glycerol water 32,300, distn. of glycerol 3500, washing the fatty acid distillate 19,300, hot presses 18,400, melting of stearin 5800, boiling of stearin 8300, molding of stearin products (candles, etc.) 35,300, drying of wickings 2000, departments not directly concerned with the manuf. 20,800, converted into mech. energy 6 kw.-hr. 5200, preheating of the feed water 40,000, undeterminable losses 46,300, sum 465,300 cal. C. A. ROBAK

**Thiocyanometry and olein.** M. DITTMER. *Seifensieder Ztg.* 56, 109-11(1929).—Polemical answer to Keller (*C. A.* 23, 2051). P. ESCHER

**Distillate olein and saponification olein.** E. SCHLENKER. *Seifensieder Ztg.* 56, 42-3, 50-2(1929); cf. *C. A.* 22, 1697.—Sapon. olein refers to the product obtained by the splitting of fats by the autoclave, Twitchell or enzyme methods, which may or may not be followed by steam distn. Distillate olein refers to fats split by  $H_2SO_4$  which yields a dark-colored product that requires subsequent distn. Formerly the distillate olein contained considerable unsapon. matter but today a properly conducted distn. furnishes a good product. The literature is contradictory as regards the definition of the 2 oleins; the usual distinguishing characteristics refer to methods of manuf. and are now only of historic value; the distinction in trade between distillate and sapon. olein should be abolished, because neither the kind of fat from which it is made, nor the method of its manuf. should be made a criterion of its quality; of sole importance are its properties and the use to which the olein is to be put. P. E.

**The occurrence of odd-number fatty acids in natural fats, oils and waxes. I.** Oil of *Datura stramonium* L. P. E. VERKADE AND J. COOPS, JR. *Niederlandische Handelshochschule, Rotterdam. Biochem. Z.* 206, 468-81(1929).—A careful study of the oil from *Datura stramonium* shows that it does not contain a 17-carbon fatty acid or its isomers. S. MORGULIS

**Iodine value of fatty acids from plant phosphatides.** J. E. WEBSTER. *Okl. Expt. Sta. Ohio J. Sci.* 29, 39-42(1929).—Acetone-insol. phosphatides from wheat, corn, soy beans and oats were prepd. The % of N was 0.99, 1.14, 0.70, 1.61; of P, 1.26, 1.65, 0.495, 0.535; the I values (Hanus) were 81.49, 65.30, 92.48, 88.80. J. J. W.

**The determination of iodine number.** J. J. A. WIJS. *Z. Untersuch. Lebensm.* 56, 488-90(1928).—See *C. A.* 23, 2052. C. R. F.

**The determination of organically combined sulfuric acid in sulfonated oils.** K. H. BAUER. *Chem. Umschau Fette Oele Wachse Harze* 36, 102(1929); cf. *C. A.* 23, 2842.—Comparative detn. of org.  $SO_3$  in sulfonated oils by the volumetric and gravimetric method showed good agreement except in one sample, contg. 10.71%  $SO_3$  (volumetric) and 10.22% (gravimetric), a difference of 0.49%. P. ESCHER

**Determination of organic sulfur trioxide in sulfonated oils.** C. RIESS. *Chem. Umschau Fette Oele Wasche Harze* 36, 77-8(1929).—See *C. A.* 23, 2842. P. E.

**Chemical composition of the oil in relation to the morphological and physiological characters of the plant.** S. FACHINI AND G. DORTA. *Giorn. chim. ind. applicata* 10, 460-2(1928).—Olive oils from the northern parts of Italy (Lake Garda, Liguria) contain only small proportions (2-6%) of linoleic acid, whereas certain oils from Southern Italy, Greece, and Northern Africa contain considerable quantities, even as much as 17%, of this acid, together with a high percentage of satd. fatty acids. This result appears to be opposite to that found by Ivanov (*C. A.* 21, 2294) for seed oils. The compn. of olive oil seems to be influenced by the age and degree of acclimatization of the plant. The characteristics of an oil depend largely on the biol. and morphol. factors of the plant furnishing it. B. C. A.

**Kenaph-seed oil.** M. R. BAUMAN. Oils and Fats Tech. Lab. *Separate* 5 pp. (1926).—The seeds of kenaph (*Hibiscus cannabinus* L., Malvaceae) of Persian origin contain 6.5% moisture, 17.9% fats (oil). The extd. oil is dark amber-yellow transparent, possesses a fairly pleasant aroma, has a fairly thick consistency and is remarkably stable, d<sub>4</sub> 0.9261, m. 6°, flame point 277.4°, sapon. coeff. 194.2, unsapon. 0.4%, Hübl I no. 100.1, glycerol contents 10.45%. The acids are palmitic 14, stearic 6, oleic 45.3, linoleic 23.4%. After refining, it will find a technical utilization as food product. BERNARD NELSON

**A preliminary note on the liver oil of the basking shark.** SIGNE SCHMIDT-NIELSEN AND SIGVAL SCHMIDT-NIELSEN. *K. Norske Videnskab. Selskab Forhandl.* 1, 5-6(1927); *Biol. Abstracts* 2, 85.—From a female of *Cetorhinus maximus* liver oil was obtained by heating the liver on a water bath in an atm. of CO<sub>2</sub> and sepg. it from the tissue. Phys. and chem. characters are given. The vitamin A content was found (by feeding rats) to be 10,000 units (U. S. P. X) while the best cod-liver oil yields only 500-1000 units. This high value may be connected with the basking habit of this species with resulting sun exposure. H. L. D.

**Studies on soap. VIII. Adsorption of soap at the contact surface of two liquid phases.** MASAO NONAKA. *J. Soc. Chem. Ind. (Japan)* 31, 297-300(1928); Suppl. Binding 31, 73; cf. *C. A.* 22, 1865.—The adsorption of the soap at the contact surface between benzene or toluene and the aq. soln. of Na oleate or palmitate was studied, Donnan's pipet being used. The adsorbed quantity is larger than the value calcd. on the basis of the theory of the monomol. layer. Therefore N. considered that the adsorbed layer is not monomol., but a monomolecular layer. The adsorbed layer consisted of the neutral soap, while the free fatty acids were dissolved in the adsorbents. When air was used as an adsorbent instead of benzene or toluene, the adsorbed layer consisted of the neutral soap plus the free fatty acids. Thus N. concluded that the aq. soap soln. consisted of aggregates of hydrated soap mols. mixed with an emulsion of the free fatty acids formed by the hydrolysis of the soap, the fatty acid being a primary adsorbate, while the aggregates of soap mols. are a secondary one. In other words, the fatty acid is first adsorbed, and when it is dissolved in the adsorbent, or is insufficient to cover the contact surface, then the aggregates are adsorbed. The adsorption phenomenon is not the same when the adsorbent is changed. Therefore the washing property of the soap, which is caused by the adsorption, will vary with the kind of the material washed. Y. NAGAI

**Recommended specification for quicklime and hydrated lime for use in soap making.** ANON. Bur. Standards, *Circ. No.* 372, 6 pp.(1929). E. H.

**Grained alabaster soft soaps.** F. S. *Seifensieder Ztg.* 56, 101-2, 111-2(1929).—A discussion of the prepn. of K soaps from soy-bean oil and tallow, and from cottonseed oil (65, 60, 65 parts) and tallow (35, 40, 45 parts), giving details of factory operations. P. ESCHER

**Method for the detection of rosin in soap.** N. SCHAPIRO. *Z. anal. Chem.* 77, 41 (1929).—The fatty acids of soap do not reduce ferricyanide but the rosin acids do. Dissolve a sample of the soap in alc., make acid with HCl and add a few drops of dil. K<sub>3</sub>Fe(CN)<sub>6</sub> soln. Heat to boiling, cool and add a drop or two of dil. FeCl<sub>3</sub> soln. A blue color indicates the presence of rosin. W. T. H.

**Soap lather.** L. ZAKARIAS. *Z. phys. chem. Seifenforsch.* 2, 18-22(1929); cf. *C. A.* 23, 1519.—Exptl. results are tabulated for several com. soaps in which the soap soln. below the lather (in a lather detn.) was made up again to the original vol., reshaken and this operation repeated until little or no lather could be produced. Total lather in mm. and total soap soln. used up by the lather in cc. are the criteria from which it was concluded that 0.15% soap is the optimum concn. for best lathering and that the "active" soap can be removed from soln. by repeated shaking as above. P. E.

**Turbidity point and hard water.** F. ENDLER. *Z. phys. chem. Seifenforsch.* 2, 34-6 (1929).—The turbidity point of a soap soln. in distd. H<sub>2</sub>O was 36°; it increased to

62° when H<sub>2</sub>O of 6° hardness (German °) was used; when H<sub>2</sub>O of 12° hardness was used no clear soln. could be obtained.

P. ESCHER

**Studies on soap solution. VI. Composition of substances adsorbed by various adsorbents.** JIRO MIKUMO. *J. Soc. Chem. Ind. (Japan)* 31, 410-6(1928); Suppl. Binding 31, 95-7; cf. *C. A.* 21, 1041.—A soln. of Na oleate was shaken with various adsorbents, then settled and filtered. The filtrate was analyzed for oleic acid and total alkali, and the av. compns. of the adsorbed matter were calcd. Carbon, fibers of filter paper, silk, artificial silk, wool, hide powder, kaolin and Japanese acid clay were used as the adsorbents. All these adsorbents react with soap, the reaction being partially chem., but generally the hydrolytic adsorption. The adsorbed matter is a mixt. of Na oleate, acid Na oleate, NaOH and their dissoecn. products. It is really neither the simple acid soap nor the simple basic soap, but only appears so as the av. of all compns. of the above constituents. The compn. of the adsorbed matter varies with the conditions of the expt. Carbon has a very large adsorbing capacity, and adsorbs only acid soap, even from alk. soln., while the others adsorb basic substances. K oleate behaves quite similarly to the Na salt. The mechanism of the washing action of the soap soln. has been derived from the results of M.'s studies of this series. It has been considered to be due mainly to 2 factors: namely, wetting and peptizing. The cleansing action is the result of coöperative action of all constituents of the soap soln., although the principal part is to be ascribed to the action of simple soap mols., simple soap ions and acid soap sol.

Y. NAGAI

**Fluorescence-analysis from the standpoint of testing materials (HAITINGER) 12. Bleaching earths (KALUSKY) 18.**

**Apparatus for extracting fats from fish meal, linseed or other materials by use of solvents.** G. W. BRADSHAW and E. R. JACKSON, *Brit.* 298,675, July 15, 1927.

**Fatty acids produced by oxidation of paraffins.** I. G. FARRENIN. A.-G. *Brit.* 299,149, Sept. 7, 1927. Dark-colored fatty acids produced by oxidation of paraffins are purified and bleached by treatment with oxidizing agents such as chromic acid, KMnO<sub>4</sub> and H<sub>2</sub>O<sub>2</sub>, suitably by heating and in stages or in an electrolytic cell contg. O-transfer agents such as chromic or ferric sulfate. KMnO<sub>4</sub> and H<sub>2</sub>SO<sub>4</sub> may be used together.

**Oils, fats, etc.** PHILIPP L. FAUTH. *Fr.* 648,707, Feb. 13, 1928. An app. is described for the sepn. of solvents from oils, fats, etc., which they contain, in which the solvent contg. the oil, etc., is sprayed into a space suitably heated and is immediately vaporized, while the sepd. oil, etc., is sprayed into another space and meets a current of steam or gas for the removal of odor or taste.

**Olive oil.** CALIFORNIA PACKING CORP. *Fr.* 649,760, Sept. 6, 1927. Olive oil is extd. by grinding and pressing the fruit so as to obtain a mixt. of oily liquid and solids in suspension, the mixt. being submitted to a pressure sufficient to bring the oil into a free state to be sepd. by centrifuging.

**Treating palm fruit to obtain oil and other products.** RUBBER CULTUUR MAATSCHAPPIJ AMSTERDAM. *Brit.* 299,061, Oct. 20, 1927. Palm fruit is subjected to low pressure to obtain oil and then passed through a drying drum and treated with an air blast to sep. nuts and pericarp.

**Thickened oil.** FERDINAND PALLAUF. *Ger.* 474,546, Jan. 14, 1926. Pure thickened oil is prepd. by maintaining wood oil, linseed oil or impure thickened oil prepd. from wood oil at 330-340° and continuously stirring. As the pure thickened oil is tapped off, an equal amt. of crude oil is admitted.

**Emulsion.** HERMANN BOLLMANN. *Ger.* 474,879, Jan. 14, 1927. An emulsion with a high m. p. is prepd. by melting 25 parts coconut oil with 25 parts of soy-bean phosphatide and stirring into 50 parts water.

**Emulsions.** FRIEDRICH BRAÜNLICH. *Fr.* 649,675, Feb. 24, 1928. See *Brit.* 285,880 (*C. A.* 23, 222).

**Soap.** SOC. ANON. POUR L'IND. CHIM. A BÂLE. *Fr.* 649,731, July 19, 1927. Insol. substances such as kaolin, kieselguhr, fuller's earth, etc., in a very fine state of division are added to soap or to the washing water. They prevent the harmful action of salts of Ca and Mg by a phys. action of a colloidal nature.

**Soft soap.** LOUIS G. LEFFER (to Hermann Bachstein). U. S. 1,710,799, April 30. Coconut oil, palm-kernel oil and rape-seed oil are caused to react with potash lye under pressure and the setting point is regulated by the addn. of hydrocarbon material such as benzene or paraffin oil during the sapon. process.

**Detergent suitable for laundering purposes.** LEE HAGER and JOHN POPPERMAN

(to Pine-O-Pine Co.). U. S. 1,710,974, April 30. Rosin is caused to react with a soln. of NaOH contg. sufficient NaOH to saponify the rosin together with a quantity of pine oil greater than the combined quantities of the rosin and NaOH. U. S. 1,710,975 specifies a compn. suitable for dry-cleaning comprising reaction products of a small quantity of NaOH, a larger quantity of rosin and a still larger quantity of pine oil at least sufficient to dissolve the rosin, mixed with a much greater bulk of gasoline.

## 28—SUGAR, STARCH AND GUMS

J. K. DALE

**Experimental sugar factory.** WALTER SCOTT. Imp. Coll. of Tropical Agr., Trinidad, B. W. I. *Sugar* 30, 550(1928); cf. C. A. 23, 2314.—The college factory is operated for the purposes of instruction to students and of research on processes. The products made are refined and plantation white sugars, Demarara crystals and table sirup. Research problems are outlined. J. F. B.

**A mathematical evaluation of the dependability of chemical control in sugar mills, especially the determination of the sugar content.** J. VONDRÁK. *Listy Cukrovar.* 47, 357-62(1929).—Errors due to analytical methods, technic and app. have decreased continually, but errors due to variations in compn., poor sampling and lack of homogeneity in a beet or in a batch remain unknown. From a distribution curve of values for deviations from a mean value of sugar content of beets for the years 1924-26 representing 1414 detns., V. concludes that for detg. the probability of error in sugar content analyses, the method of Gauss may be depended upon. The av. variation of an individual reading from a mean is computed according to the relation:  $m = \sqrt{\Sigma[v^2]/n-1}$ , where  $v$  is the deviation, and  $n$  is the no. of detns. or deviations. FRANK MARESH

**Examination of raw sugars, using a single solution.** J. VONDRÁK. *Z. Zuckerind. tšechoslovak. Rep.* 52, 381-8(1928).—Twice the normal sugar wt. is dissolved in water, and made up to 200 cc. at 20° (without the usual clarification). Some of this liquid is used for the moisture detn. by means of the new Zeiss refractometer and prism No. II, the percentage result being obtained from a table specially compiled by the author, making a correction for any deviation from 20°. A further portion of the soln. is used for the ash detn. by means of Šandera's app. (cf. *Z. Zuckerind. tšechoslovak. Rep.* 51, 603-12(1927)). To the remaining portion of the soln., about 100 cc., is added dry basic Pb acetate (about 0.25 g. for first-product raw sugars, and 0.5 g. for after-products), the polarization being read after mixing and filtering. Compared with the present method of analyzing sugars, this rapid method gave sufficiently const. and close results, the rendement in the case of first-products never differing by more than 0.16. B. C. A.

**Ash determination in moist and refined sugars by electric conductivity.** K. ŠANDERA AND B. ZIMMERMANN. *Z. Zuckerind. tšechoslovak. Rep.* 52, 405-12(1928); cf. C. A. 23, 297.—The authors have designed a cond. app. suitable for detg. the low-ash contents of refined sugars. The 2 electrodes consist of a gilt brass tube and a rod fixed axially within it by an insulating plug at the upper end. This electrode system is immersed to a standard depth in the sugar soln. to be tested, which contains 26 g. of sample per 100 cc. As in previous instruments (C. A. 21, 3481; *Z. Zuckerind. tšechoslovak. Rep.* 51, 603-12(1927)), the use of the telephone in balancing the resistances is superseded by an optical method. Results for a no. of Czechoslovakian refined sugars are tabulated. B. C. A.

**Studies on the composition of sugar obtained by complete hydrolysis of pine wood.** I. ERIK HÄGGLUND. Inst. für Holzchem., Åbo, Finland. *Biochem. Z.* 206, 245-7(1929); cf. C. A. 22, 4861.—On hydrolysis of pine wood with HCl, the diffusion method being used, a product is obtained contg. large amts. of a methoxyl substance, which is very sol. and which unlike lignin-HCl loses most of the methoxyl on hydrolysis with hot dil. acids or by yeast fermentation. S. MORGULIS

**The cane improvement at the experimental station for the Java sugar industry at Pasoeroean.** O. PUSTHUMUS. *Arch. Suikerind., Mededeel. Proefsta. Java Suikerind.* 36, III, 991-1022(1928).—A review is given of the breeding of new varieties during 1926, 1927 and 1928. P. R. P.

**The cane position in North Bihar with special reference to the factory industry and the early crushing problem.** WYNNE SAYER. *Agr. J. India* 23, 424-31(1928). K. D. JACOB

**Target blotch of sugar cane.** C. N. PRIODE. *Facts About Sugar* 24, 376(1929).—

An infectious disease, previously unreported, caused by a *Helminthosporium* fungus, which produces blotches of irregular concentric rings, has been discovered in Cuba. Probably it will not cause serious damage to the varieties of cane now being grown commercially there, but further studies are being made.

M. J. PROFFITT

**Preservation of raw cane juice.** EUGENE LOUMÉAN. Trinidad, B. W. I. *Sugar* 30, 491-3(1928).—The efficiency of various preservatives was studied with the object of ascertaining which is most suitable for the keeping of the 12 hr.-composite sample. When thoroughly incorporated with fresh juice in clean containers, Horne's dry Pb acetate, 6 g. per l.,  $\text{HgCl}_2$ , 0.25 g. per l.,  $\text{HCHO}$ , 40%, 10 cc. per l.,  $\text{C}_6\text{H}_5\text{CH}_3$ , 5 cc. per l., render the juice sterile for periods much longer than are required in the routine chem. control of cane-sugar factories. Any small loss occurring is due to enzymes present in the juice. The effect of basic lead acetate as a preservative according to the expts. is greatest, and that of toluene least.

J. F. BREWSTER

**Boiling of white sugars.** F. NOSEK. *Z. Zuckerind. Tschoslovak. Rep.* 52, 441-7 (1928).—Insol. particles in the liquor from which white sugars are boiled (fibers, char dust, mineral matter, etc.), if sufficiently fine, may serve as grain in the subsequent crystn., causing the sugar to be dull. Their presence is therefore to be avoided, though the grayish tinge of granulated sugar may also be due to occluded air bubbles. In forming grain by "seeding," the sugar dust used should be boiled from the best liquors, and care must be taken to disperse it thoroughly throughout the contents of the pan; otherwise conglomerates are formed. Dust obtained by grinding is less suitable than specially boiled very fine grain. Fine "pilé" should not be used. In boiling white sugars the formation of the grain and its growth can be followed to advantage under the microscope, and useful information is thus obtained as to the conditions requisite for the production of uniform crystals.

B. C. A.

**Manufacture of white sugar at cane-sugar factories.** P. HONIG. *Arch. Suikerind.* 37, I, 113-28(1929).—The manuf. of plantation white sugar of the same quality as refined sugar is possible when attention is paid to the raw materials. As far as possible sirup and runoffs should always be of the same quality. The boiling should be done in 4 Strikes; the low-grade sugar, not used for seeding 2nds, should be remelted, clarified and filtered. Special attention should be paid to the washing of the sugars at the centrifugals as the film of molasses affects the color of the sugar to a greater extent than the impurities incorporated in the crystals.

P. R. P.

**Standardized inversion of cane or beet sugar gives best results with  $p_H$  control.** A. A. SCHAAL AND OTTO JOHNSON. Biscuit and Cracker Mfrs. Assoc., Minneapolis. *Food Industries* I, 266-9(1929).—The colorimetric method of detg. H-ion concn. is suitable for invert sugar control. The following forms a good basis for making invert sirup: sugar 100 lb., water 33 lb., tartaric acid 2 oz. for high-grade cane sugar, 3 oz. for low-grade cane or high-grade beet sugar, 4, 5, or 6 oz. for low-grade beet sugar. The water and sugar are heated to boiling, preferably in a glass-lined, steam-jacketed kettle equipped with cold-water circulation in the jacket and with a stirrer to insure const. agitation. When the sirup reaches the b. p., the acid (previously dissolved in a small quantity of  $\text{H}_2\text{O}$ ) is added and the boiling continued for 30 mins. The sirup is then cooled as quickly as possible. Some means of quick cooling, such as circulating cold water in the jacket with which the kettle is surrounded, is essential for the production of light-colored sirups. Beet sugars are more highly buffered than cane sugars, although both can be used with satisfaction provided the  $p_H$  of the batch is controlled. Inversion of the sugar does not change the  $p_H$  of the sirup to any noticeable extent. If a neutral sirup is desired,  $\text{NaHCO}_3$  is added after cooling. A rough pos. correlation may be drawn between the ash content and the buffer action of a sugar in the range of  $p_H$  necessary for inversion. It is not safe to judge sugars for inversion purposes solely by this criterion, however.

C. R. F.

**Method of determination of sugar in fresh slices of beet in relation to the calculation of loss in sugar manufacture.** A. DOLINEK. *Z. Zuckerind. Tschoslovak. Rep.* 52, 329-33(1928).—It is recommended that the official pipet method, employing the single normal wt. of pulp and 308 cc. of dil. basic Pb acetate for the detn. of sucrose in fresh slices, should be abandoned in favor of either of the following two: (1) That in which double the normal wt. of pulp is treated with 354 cc. of dil. basic Pb acetate; or (2) that in which a proportionate amt. of pulp is mixed with 308 cc. of dil. basic Pb acetate from an automatic pipet. Both give satisfactory results compared with the Herles hot-water digestion process, whereas if the above official method be employed in control, the losses indicated may be too high by 0.13% of the sugar in the beet.

B. C. A.

**The determination of sugar in the beet or the cossettes: the volume occupied by**

the marc and the water digestion. EMILE SAILLARD. *Planter and Sugar Mfr.* 82, 123-4(1929).—The most exact method is hot-water digestion (1) in a graduated flask using chopped beets or cossettes and not fine pulp. The Sachs le Docte method (2) is more exact than the Kayser-Lewenberg (3) but not so exact as (1). The difference between the latter 2 methods is in the normal wts., 16.26 g. for the former and 26 g. for the latter. Flasks should be graduated to 401.8 cc. for 52 g. pulp and to 201.2 for double the French normal wt., 32.52 g. Assuming a marc content of 5% in beets and a juice density of 1.085 the vols. of  $H_2O$ , and of Pb subacetate mixt. to be used in methods (2) and (3) are calcd. For method (2) and 26 g. normal wt., 177.24 cc. must be added; for method (2) and the double normal French wt., 32.52 g., 171.53 cc. and for method (3) and the German double normal wt., 52 g., 154.48 cc. The results of polarization are given for dried and undried pulp using method (2). J. F. B.

Storing beets by drying. G. S. BENIN. *Nauchnuie Zapiski* 6, 68-71(1928); cf. C. A. 22, 181.—B. made an expt. on storing dry beet cossettes. Two portions were kept for 1 yr.—one in the lab. with temp. variation from 10° to 20°, the other in an outside refrigerator subjected to atm. changes, but protected from rain and snow. After 6 months the samples were retested. The lab. sample remained almost without change; the other had increased in  $H_2O$  from 5.22 to 8.56%. The humidity of the air was 68-77%. During the second part of the year (Sept.-Feb.) the humidity of the air was 74-83%, and  $H_2O$  in cossettes increased to 13.14%. The temp. variation for the year was from -9.3° to +20.7°. Loss of sugar was only 0.2% on the wt. of the raw beets. Increase of invert sugar was slight. The limit of drying can only be detd. by expt. made on a large amt. of dry cossettes as only ext. layers absorb  $H_2O$ . V. E. B.

Working white sugar massecuites (in the beet-sugar factory). F. NOSEK. Z. *Zuckerind. tšechoslovak. Rep.* 52, 457-61(1928).—Microscopic observation of the centrifuging of granulated massecuites shows that the mother liquor frequently contains such an amt. of extremely fine grain as to impart to it a milky appearance. On turning on cold or particularly hot water for covering, after the adhering sirup has been washed out, the crystal begins to be attacked. Steam has a similar effect, though less severe than hot water, but it also causes the formation of fissures in the wall of sugar in the centrifugal through which the condensed water penetrates, causing further etching of the crystal. B. C. A.

Formation of incrustation on evaporators (of beet-sugar factories). V. STANĚK AND P. PAVLAS. Z. *Zuckerind. tšechoslovak. Rep.* 52, 545-60(1928).—Incrustation formation in beet-sugar factories depends largely on the nature of the heating surface. Thus, on brass polished brightly the percentage of incrustation and of suspension was 97.7 and 2.3, and on rough brass 94.6 and 5.46. Similarly, a copper-plated surface gave 67.3 and 32.7, and one which had been tinned 51.3 and 48.7.  $CaCO_3$  present as aragonite formed centers for the crystallization of the  $CaCO_3$  sepd. from a beet juice, which had been over-carbonated; but  $CaCO_3$  added in the amorphous form merely adhered to the heating surface, increasing the amt. of the scaling. On the other hand, fine carbons (particularly "Norit") acted favorably in diminishing the amt. of the scaling. A weak elec. current between the heating surface and an electrode placed in the liquid exerted an unimportant, though detectable, effect. B. C. A.

Boiling-up of thin juice. V. MAJER. Z. *Zuckerind. tšechoslovak. Rep.* 52, 465-79 (1928); cf. C. A. 21, 1562.—If the carbonation of beet juices is carried beyond the correct alk. (0.01%  $CaO$ ) so that more or less bicarbonate is formed, the pptn. of  $CaCO_3$ , which occurs on subsequent boiling, is much slower and less complete than would be the case with pure solns. of  $CaHCO_3$ . This delayed pptn. is largely due to the influence of sugar and amino acids. Boiling for 20-30 mins. is necessary to remove most of the precipitable lime compds. By working to an alk. corresponding to 0.01%  $CaO$  in the carbonated juice, the total lime content of the juice and the amt. pptd. on boiling for 30 mins. are both reduced to a min. A deviation of 0.01%  $CaO$  from this optimum alk., in either direction, increases considerably the amt. of ppt. (chiefly  $CaCO_3$ ) produced on boiling, and therefore increases the amt. of evaporator incrustation unless the juice is boiled up before entering the evapg. plant. B. C. A.

Final saturation of (sugar) thin-juice. O. SPENGLER AND C. BRENDL. Z. *Ver. deut. Zuckerind.* 76, 637-43(1928).—To obtain juice low in Ca the second carbonation is carried out so as to sat. the natural alk., after which follow successively heating, filtration, sulfitation almost to neutrality at high temp., and a second filtration. At this stage  $Na_2CO_3$  is added in amt. corresponding to the content in Ca present, the juice being lastly boiled and filtered. If at the sirup stage the alk. is too high, it can be reduced by sulfiting. B. C. A.

The composition of juices from the 1928-29 season. J. VONDRÁK AND B. ZIMMER-

MANN. Expt. Inst. Cz. Sugar Ind. (Prague). *Listy Cukrovar.* 47, 325-30(1929).—A statistical report covering the reports sent in from 87 mills in Czechoslovakia representing over 50% of the sugar industry. Detailed tables are given for an 8-year comparison of  $N_2$  in various forms of diffusion and concd. liquors, of the nature of complaints in the various processes and of chem. control of the raw material and product. Averages for the preceding 9 yrs. are given. FRANK MARESH

The evaporation of sugar juices in the presence of activated charcoals. VL. STANĚK AND P. PAVLAS. Exp. Inst. Cz. Sugar Ind. (Prague). *Listy Cukrovar.* 47, 317-22(1929).—Sugar juices after the first satn. were treated with "standard norite," "supra-norite," "superior norite," carboraffin, basswood charcoal, infusorial earth boiled with acids and ignited, aragonite freshly prepd. by pptg.  $CaCl_2$  with  $Na_2CO_3$  at boiling temp. and a mixt. of norite +  $Na_2SO_3$ . The presence of insignificant quantities of charcoals affects the final color of the soln. very favorably and decreases the formation of more coloring matter. The various com. grades of norite vary among themselves but improve the color 67-100%; standard norite was found to be the best; the final color of the soln. is not dependent upon the decolorizing power of any grade of norite. Carboraffin was more effective than the standard norite. Infusorial earth, wood charcoal and aragonite do not increase the coloration of juices during evapn. as compared to untreated samples, but may even decrease the color. The most favorable results were obtained with the combination of activated charcoal and  $Na_2SO_3$  in that the juice was more lightly colored after evapn. than before evapn. was begun. Increasing quantities of charcoal exhibit an unproportional decrease of color in the evapd. soln. An increase of 0.01% is without an effect probably because of satn. of the whole surface by non-sugars. Juices of various origins give varied results during evapn. with activated charcoals; this applies equally to juices which were not treated with decolorizing agents. The combination norite +  $Na_2SO_3$  is to be tried in the next season. FRANK MARESH

Methods of decolorizing sugar solutions by means of active carbons. V. ŠÁZAVSKÝ. *Z. Zuckerind. čechoslovak. Rep.* 52, 413-20(1928).—In the suspension method a certain amt. of the C is mixed with the juice during 15 mins. at about 80° and pumped through filters of suitable type, while in layer filtration the C is previously deposited in a layer about 25 mm. thick and the liquor under decoloration pumped through this. In the latter method a better utilization of the C is realized by working in 2 stages so that the liquors are passed first through almost exhausted C and subsequently through fresh material. Some factories use a combination of the suspension and layer methods. Which method is the more suitable depends mainly on the nature of the C and on the liquors under treatment. In general, the layer method in two stages is the more favored for high-power carbons. B. C. A.

Bone charcoal and active vegetable carbons [in sugar refining]. C. MRASEK. *Z. Zuckerind. čechoslovak. Rep.* 52, 174-6(1927).—Bone charcoal is considered to give more regular and surer working, and, contrary to Wiesner's views, it is more economical than vegetable carbons. B. C. A.

Decolorization of sugar juices by active carbons. F. NOSEK. *Z. Zuckerind. čechoslovak. Rep.* 52, 269-72(1928).—A commentary on recent papers by Wiesner (*C. A.* 22, 2287) and Mrasek (cf. preceding abstract) on the use of active carbons in refinery and factory working. B. C. A.

Clarification of sugar solutions for polarimetry. V. ŠÁZAVSKÝ. *Z. Zuckerind. čechoslovak. Rep.* 52, 669-72(1928).—If 26 g. of beet molasses is defecated with basic Pb acetate soln. and made up to 100 cc., the vol. of the ppt. causes an error of about +0.26 on a polarimetric reading of 50. Such errors are avoided by the use of Horne's dry basic Pb acetate defecant, added after the molasses soln. has been made up to vol. A slight error in the opposite sense arises, however, from an increase in vol. of the liquid due to the space occupied by the excess of defecant in the dissolved state. Excess of defecant must be used to obtain the necessary degree of decolorization, and an excess of 1 g. is found to cause an error of -0.09 on a Ventzke reading of 50°. B. C. A.

Objective measurement of color in sugar manufacture. K. ŠANDERA. *Z. Zuckerind. čechoslovak. Rep.* 52, 261-9(1928).—The author has designed an instrument for measuring intensities of light by means of the photoelectric current produced at a surface of metallic K in a photoelec. cell. It consists of a 100-watt lamp with light filters and stops, from which the light passes through a glass cell contg. the liquid under examn. to a photoelec. bulb or cell contg. a film of K and a grid anode. The current, which passes between the film and the anode on illumination, is amplified by a 3-electrode thermionic valve and measured by means of a millivoltmeter. For light of given quality the photoelec. current is, within wide limits, proportional to the in-

tensity of illumination. Measurements made on sugar juices at various stages of manuf. show agreement of duplicate readings to within 1 in 150. The instrument can be used to measure not only color intensities, but also turbidities. B. C. A.

**Rate of solution of sucrose under various physical and chemical conditions.** V. NEUKA. *Z. Zuckerind. tšchoslovak. Rep.* 52, 289-93(1928).—Using similar app. to that of Šandera (cf. preceding abstract), the author investigated the rate of soln. of pellets of amorphous sugar prep'd. by allowing drops of molten sugar (contg. 2-3% of moisture) to fall into cold Hg. The relative rates of soln. of these pellets in pure water at 20°, 40° and 70° were approx. in the proportions 1:14:13. At a const. temp. of 20° the rate of soln. in pure water was twice that in 18% sucrose soln., and about 10 times as great as the rate in 50% sucrose solns. In lime water, in 1% solns. of  $K_2SO_4$  and oxalic acid, and in 5% soln. of  $Na_2CO_3$ , the pellets dissolved rather less rapidly than in pure water, but the max. observed reduction in rate was only about 5%. In molasses solns. also the rate of soln. was less than in pure water, mainly because of the sugar and only to a slight extent because of the salts present. The rate of soln. of sugar crystals in pure water at 20° showed occasional differences beyond the limits of exptl. error. It is suggested that crystals formed slowly in the cold may dissolve more slowly than those formed under the usual tech. conditions. B. C. A.

**Influence of over-saturation (in the carbonation process) on the precipitation of some acids in presence of magnesia and alkalies.** R. KARGL. *Z. Zuckerind. tšchoslovak. Rep.* 52, 253-9(1928).—Pptn. of the vegetable acids present in beet juices during carbonation, after having added lime contg. MgO, depends on several factors, but especially on the alky. of the carbonated juice. The presence of alkalies has an adverse effect, lowering the efficiency of the clarification and causing oversatn. MgO exerts no influence so long as its amt. does not exceed that of the lime used. B. C. A.

**Cutting sugar costs by modern methods.** N. A. HELMER. *Sugar* 31, 95-7(1929).—A description with illustrations of the Dorr clarifier and the Petree-Dorr process. J. F. B.

**Experiments with Sweetland and Kroog filter presses.** C. SYLMANS. *Arch. Suikerind., Mededeel. Proefsta. Java Suikerind.* 37, III, 11-55(1929).—During the crop 1928 comparative tests were made at Redjoagoeng with Sweetland and Kroog filters. A description of the Sweetland is given. Results are given in tables and graphs. Capacity of the Sweetland was 15% more than that of the Kroog and sweet water required for Sweetland was 50% larger than that for the Kroog. The Sweetland requires less cloth, less labor and less renewing of spare parts. The Vallez filter is discussed. The capacity of this filter is about 3 times greater per sq. unit filtering surface than that of the Kroog. P. R. P.

**Final report of 1928 manufacturing control.** C. SYLMANS. *Arch. Suikerind., Mededeel. Proefsta. Java Suikerind.* 37, III, 57-135(1929).—Av. results of 175 mills are reported, 60 sulfitation, 42 carbonation and 73 defecation. This year besides the gravity purity of final molasses the sucrose purity is also reported. Instead of Geerlig's formula for available sugar Winter's formula is used. The av. sucrose purity of final molasses sucrose in product

of all mills was 34.4. The av.  $\frac{\text{sucrose in juice}}{\text{sucrose in product}} = 90.7\%$ .

**Carbonation process control.** R. T. BALCH AND J. C. KEANE. *Sugar* 30, 534-6(1928).—A description is given of an automatic control of the second carbonation in a beet-sugar factory by change in  $p_H$ . A satd.  $Hg_2Cl_2$  half cell has contact with the juice through a porous cup filled with KCl, constituting the salt bridge. The other electrode is a bare W wire. These were connected with a recording potentiometer with a device for controlling a motor, which operates the gas valve (cf. C. A. 22, 1628). The juice was cooled to 30-35° by passing through a water-jacketed pipe. The "anticipatory control" acts in such a manner that the gas valve is gradually opened when the reaction of the juice is above the desired  $p_H$  and still going higher, and is gradually closed when the  $p_H$  is too low and still going lower. The article is illustrated with photographs showing the installation of electrodes, reversing motor and recorder controller; a chart is reproduced showing records of fluctuations in  $p_H$ . J. F. B.

**Determination of the dew point of flue gases.** J. J. DEN HAAN. *Arch. Suikerind.* 36, II, 1283-91(1928).—All processes where heating is done by vapor-contg. gases are affected by the position of the dew point. H. has computed and constructed a graph indicating the dew point, when the  $CO_2$  of the flue gases and the moisture of the bagasse are known. P. R. P.

**Determination of starch in grain and milling products.** C. VON SCHEELE AND G. SVENSSON. *Tek. Tid., Uppf. C, Kemi* 58, 57-60 and 65-72(1928).—A difficulty

in the detn. of starch in grain and milling products is caused by the hemicellulose compds. that always accompany the starch. In particular the pentosans are far less resistant to the action of chem. reagents than cellulose and are obtained in soln. by the action of enzymes or even by treating with water only. An accurate method of analysis should eliminate or take into account the sources of error arising from the presence of both sucrose and hemicellulose. The following methods have been examd. by the authors: (1) Detn. of starch was by difference, 100% - (fat + protein + ash +  $H_2O$  + pentosans), each analysis having been carried out according to standard methods.  $H_2O$  was detd. by drying for 6 hrs. at  $120^\circ$ . (2) Diastase-treatment was carried out according to M. Märcker, *Handb. der Spiritusfabrikation*, Berlin, 1898. The amt. of maltose formed was detd. iodometrically according to I. M. Kolthoff, *C. A.* 17, 2252. The quantity added of 0.1 N  $I_2$  should be not less than twice the theoretical amt. and the quantity of 0.1 N KOH should be about 20% more than the quantity of 0.1 N  $I_2$ . The procedure described should be followed carefully in all details. (3) Hydrolysis according to Fellenberg (see Kolthoff, *loc. cit.*) was carried out in a N soln. of HCl, the time required have been 45-90 mins. (4) Detn. of pentoses was carried out according to Tollens. The amt. of pentosans in barley was calcd. from the tables of F. Pawlowski, *Die Brautechnischen Untersuchungsmethoden*, p. 37. In all other grain products the tables of Tollens had been used, calcd. as a mixt. of equal parts of araban and xylan. (5) Hydrolysis with HCl in an autoclave under 3.5 atm. pressure and detn. of starch as dextrose with Fehling soln. were carried out according to Reinke, see O. Saare, *Die Fabrikation der Kartoffelstärke*, p. 491, Berlin, 1897. (6) Diastase treatment and dextrose detn. with Fehling soln. (Märcker, *loc. cit.*) were used. (7) The inversion method of Lintner, see J. König, *Untersuchung von Nahrungs-Genussmitteln und Gebrauchsgegenständen*, p. 141, Berlin, 1910, was used. (8) The method of Ewers, *Zeitschr. f. öffentl. Chem.* 14, 8, 150(1908); 15, 8(1909), hydrolysis with HCl, pptn. of proteins with 4% phosphotungstic acid and detn. of sugar by polarization were carried out. (9) The method of Lintner-Schwarz, *Z. ges. Brauwesen* 1913, 101, hydrolysis with alc. and  $H_2SO_4$ , pptn. of proteins with phosphotungstic acid, polarization were used. (10) The method described by A. Ling, D. Nanji and W. Harper (*Wochenschrift f. Brauerei*, p. 206(1924); cf. *C. A.* 19, 1836) and improved by H. Lüers and F. Wieninger, *Zeitschr. f. d. ges. Brauwesen*, June, 1925, was used. A number of tables shows the results obtained in different grain materials by the different methods as well as the corrections to be applied in each case. The improved method (10) of Lüers and Wieninger is considered the most accurate and requires only a correction for water-sol. substances. Although it is very tedious, it should be considered a valuable standard checking method. A sufficiently accurate method is the detn. by polarization after diastase-treatment (11), which is recommended for laboratories where the number of starch detns. is not very great. The results obtained are generally a little lower than those obtained by method (10). For laboratories having a large number of starch detns. the method of Ewers (8) should be preferred as the routine method, the necessary corrections always being taken into account. It is particularly suited for comparison detns. and is the most rapid method of those examd. (2) is usable but has no advantage over the polarimetric method and is slower than the latter. The methods (8), (10) and (11) are described in detail and are suggested as standard laboratory methods.

The acids of gum arabic. L. AMY. *Bull. sci. pharmacol.* 36, 7-17(1929).—See C. A. 23, 478. C. A. ROBAK A. E. MEYER

How does  $CO_2$  behave under pressure? (KRASE, GOODMAN) 2. Composition of gum arabic (BUTLER, CRETCHER) 10.  $CO_2$  assimilation of the sugar beet (LUNDEGÅRDH) 11D. What amounts of nutrient substances present in the effluent of a potato-starch factory are adapted to meadow irrigation? Are these poisonous to fish? (EBELING) 14. The effect of some growth conditions on chemical composition and metabolism in the sugar-cane leaf (FOLLETT-SMITH) 11D. Influence of the distance between rows of sugar beets upon the absorption of nutrition from the soil (Souček) 15. Mixing gases and liquids [treating sugar juices with  $SO_2$ ] (Fr. pat. 648,462) 13. Effecting chemical reactions [hydrolysis of starch] (Ger. pat. 474,075) 13.

Sugar. RAFFINERIE TIRLEMONTAISE SOC. ANON. Fr. 649,993, Feb. 28, 1928. Brit. 286,599 (*C. A.* 23, 540).

Washing crude sugar. LOUIS É. HYVE. Fr. 649,929, Aug. 3, 1927. Crude sugar made into a paste with sirup liquor from a previous operation is passed up an inclined

shaft by means of a spiral screw in the form of a sieve, against a descending current of sirup liquor.

**Continuous sugar-extraction process.** N. NOBEL. Brit. 298,501, July 4, 1927. In extg. sugar from materials such as bagasse the material is forced to flow with and by the greater part of the extg. liquid in a closed circuit in an app., which is described, the liquid continuing to circulate after the solid residue has been removed from the circuit.

**Sugar solutions.** KARL KOMERS and KARL CUKER. Fr. 648,450, Feb. 6, 1928. Instead of protecting sugar solns. from oxidation, they are freely oxidized by passing a current of air through the solns. until they no longer darken in color. They are clarified by the addn. of lime or superphosphate.

**Purifying molasses, etc.** KARL KOMERS and KARL CUKER. Austrian 112,637, Nov. 15, 1928. The purification of molasses and the like with suitably pretreated slices of beet is improved by adding to the beet finely divided inert substances such as active C, charcoal, cellulose, or hydrocellulose. Metals, metal oxides, or salts may also be added or may be pptd. in the soln. to be treated. App. is described.

**Starch.** CORN PRODUCTS REFINING CO. Fr. 649,985, Feb. 28, 1928. See Brit. 277,572 (C. A. 22, 2680).

**Starch.** SÄCHSISCHE KLEBSTOFFWERKE G. M. B. H. Ger. 474,602, Nov. 21, 1924. Cold-water starch preps. are made by mixing 100 parts of air-dried starch with 3 to 4 parts of finely divided chlorinated hydrocarbon and treating the mixt. with alkali lye.

**Starch.** FRANZ RIETHOF. Austrian 112,641 and 112,647, Nov. 15, 1928. Starch that swells in cold water is prepd. by mixing dry starch with about 3% of amyl alc. (112,641) or 3-5% of an aromatic amine (112,647), treating the mixt. with NaOH soln., and neutralizing, preferably with a solid acid, e. g., (COOH)<sub>2</sub>, or an acid salt, e. g., NaHSO<sub>4</sub>.

**Hydrolysis of starch.** VEREIN DER STÄRKE-INTERESSENTEN IN DEUTSCHLAND. Ger. 473,453, Feb. 8, 1924. A product as sweet as ordinary sugar is prepd. by treating starch with very dil. acid under moderate pressure in the presence of *p*-phenetolecarbamide.

## 29—LEATHER AND GLUE

ALLEN ROGERS

**The microscopic examination of vegetable tannins by means of polarized light.** II. B. AVENATI-BASSI AND G. A. BRAVO. *Boll. ufficiale staz. sper. ind. pelli mat. concianti* 7, 64 9(1929).—In continuation of previous studies (C. A. 22, 2854) A. and B. examd. the barks of *Eucalyptus*, poplar, birch, pine and alder by comparing the photomicrographs taken in ordinary light with those obtained in polarized light. G. SCHWOCH

**Tannin extract plant at Crawley, Western Australia.** N. T. M. WILSMORE. *Chem. News* 137, 278-80(1928).—A semi-com. scale ext. plant has been built by the Australian Council for Scientific and Industrial Research in coöperation with the Univ. of Western Australia, for the purpose of detg. the best methods of extg. Australian tanning materials. The equipment consists of Van Gelder crusher and disintegrator, Sirocco dust fan, Cyclone separator, 6 leaching vats, 2-stage evaporator, Kestner drier and special app. for treating barks under pressure or with chemicals.

H. B. MERRILL

**Reactions of tanning materials.** M. DUJARDIN. *Boll. ufficiale staz. sper. ind. pelli mat. concianti*; *La chimica* 5, 33(1929).—Cellulose tanning exts. are often viscous, although of low d. Myrabolan exts. have a characteristic odor; chestnut exts. have less than 1% ash and oak-bark exts. more. After examg. cellulose and synthetic tannins separately, a 0.4% soln. of the ext. is prepd. in the warm, followed by cooling and filtration. A mixt. of 50 cc. of the soln. with 10 cc. 40% formaldehyde and 5 cc. concd. HCl is then boiled, a reflux condenser being used. Catechuic tannins give a flaky ppt., red for mangrove, pink-brown for mimosa, etc. When no ppt. is formed after 1/4 hr., no catechuic tannins are present. After boiling, during 1/2 hr., cool and filter, adding to 100 cc. of the filtrate 5 g. crystd. Na acetate and 1 cc. 1% Fe alum soln. Pyrogalllic tannins give an intense violet. An abundant ppt. with formaldehyde and no color with Fe alum indicate catechuic tannins; absence of a ppt. and a violet-blue color with Fe alum indicate pyrogalllic tannins; and an abundant ppt. with formaldehyde and violet-blue color with Fe alum indicate both pyrogalllic and catechuic tannins.

R. SANSONE

**Chemistry of the liming process.** A. STEIGMANN. *Collegium* 1928, 653-7.—Lime

is as active as 8% NaOH in decomp. cystine, after the reaction starts. Besides sulfide, a complex compd. of  $\text{Ca}(\text{OH})_2$  and cystine, which is not Ca cystinate, is formed. Photographically inactive gelatin can be sensitized with  $\text{Ca}(\text{OH})_2$  and  $\text{Na}_2\text{S}$ . One kg. of cystine combines with 67.5 g. of  $\text{Na}_2\text{S} \cdot 9\text{H}_2\text{O}$  and 1 kg. of gelatin with 0.45 g. If the  $\text{Na}_2\text{S}$  was combining with cystine, 3.5 g. per kg. would be present in the gelatin but a tenth of this quantity would prevent inertness; so other groups must combine with  $\text{Na}_2\text{S}$ . Probably in lime liquors the cystine decomposes to  $\text{Na}_2\text{S}$  and this then combines with hide substance. I. D. C.

Progress in the treatment of tannery wastes (HODGE) 14. Sanio's  $\text{K}_2\text{Cr}_2\text{O}_7$  test for tannins (FEAR) 7. Detection of gallic acid and tannin (CELSI) 7. Varnish for shoes (Swiss pat. 130,137) 26. Wetting agents (Brit. pat. 298,559) 25. Sodium cellulose waste [tanning agent production] (Ger. pat. 472,680) 23.

GERNGROSS, O.: *Fortschritte auf dem Gebiet der Gerberei-Chemie und- Technik*. Berlin: Verlag Chemie, G. m. b. H. 42 pp. M. 2.50.

Process and product for unhairing and dewooling skins without attacking the hide or hair. M. MARTENS. Belg. 353,899, Oct. 31, 1928. The product consists of a mixt. of 1 part NaHS crystals ground to an impalpable powder, 4.5 parts of kaolin ground to an impalpable powder and 4.5 parts of very finely ground sawdust.

Mechanical and chemical process for dehairing and dewooling hides. M. MARTENS. Belg. 353,900, Oct. 31, 1928. The hides are hung so as not to touch one another in a chamber through which an aq. soln. of NaHS is circulated vertically.

Preserving hides and skins prior to tanning. H. DODGE. Brit. 298,435, Feb. 20, 1928. A compn. comprising  $\text{CH}_2\text{O}$ , niter,  $\text{NaHCO}_3$  and  $\text{Na}_2\text{SO}_4$  may be used as a dry mixt. and rubbed into the flesh side of the hides or skins or mixed with salt if the latter is used; it may be used in aq. soln. with agitation or as a spray.

Treating skins. HARRY DODGE. Fr. 649,812, Feb. 25 1928. Skins are treated with a soln. in water of  $\text{CH}_2\text{O}$ ,  $\text{KNO}_3$ ,  $\text{NaHCO}_3$  and  $\text{Na}_2\text{SO}_4$  to improve their quality after tanning. Cf. C. A. 23, 543.

Tanning material. J. R. GRIGY A.-G. Swiss 130,434, Aug. 13, 1927. A synthetic tanning material free from mineral acids is formed by mixing the dried reaction products of hydroxysulfonic acids and  $\text{HCHO}$  with fluosilicates. Thus, the reaction product of cresolsulfonic acid and  $\text{HCHO}$  is neutralized with  $\text{Na}_2\text{CO}_3$  and dried. With this product is mixed dry  $\text{Na}_2\text{SiF}_6$  in the proportions 100 to 50. The resulting mass contains 40-50% tanning material. Another example mentions naphthol- or phenolsulfonic acid as the starting point. Cf. C. A. 22, 2488.

Dye preparation for use on leather, etc. E. COMES. Brit. 298,565, Oct. 11, 1927. A compn. for dyeing leather, etc., comprises a fatty substance, a dye, acetone and other org. solvents; e. g., stearin, turpentine oil and Fat-Ponceau are warmed together, mixed with benzine or "petrol," allowed to stand and finally mixed with acetone.

Leather substitute. LONZAWERKE ELEKTROCHEMISCHE FABRIKEN GES. Brit. 299,023, Oct. 19, 1927. Fibrous material such as long staple cotton (with or without admixt. of animal fibers) is kneaded, preferably at low temp., with a binder such as single or mixed cellulose derivs. or a mixt. of these with albumin; the mixt. is forced through slotted apertures into a coagulating bath or a series of coagulating baths; it may subsequently be treated with finishing or coating compns. and may be subjected to mech. treatments such as calendering, embossing, or goffering.

Glue from chrome-tanned leather. ADAM HOCHÉ (to Litmo Adhesive and Products Co.). U. S. 1,710,687, April 30. Chrome-tanned leather contg. 2-5% Cr oxide is extd. at room temp. in successive baths of  $\text{H}_2\text{SO}_4$  of about 20° Bé., about 10° Bé. and about 5° Bé. (each extn. being for about a half hr.); the extd. leather is then heated in water to form a water-proof glue contg. some Cr oxide.

Glue. KARL KLINGSPO. Fr. 649,309, Dec. 22, 1927. See Brit. 293,232 (C. A. 23, 1524).

Metal-glutin compounds. KARL KÜTTEL. Austrian 112,642, Nov. 15, 1928. Glue or gelatin soln. is treated first with a slight excess of an alkali-hydroxide or carbonate soln. and then with a salt of a bi- or trivalent metal, whereupon an insol. "glutinate" is pptd. The products give an artificial horn when hardened with  $\text{CH}_3\text{O}$ . Cf. C. A. 22, 4739.

# CHEMICAL ABSTRACTS

Vol. 23.

JULY 10, 1929

No. 13

## 1—APPARATUS AND PLANT EQUIPMENT

W. L. BADGER

Two new laboratory apparatus. HANS J. FUCHS. Wassermann Inst., Berlin. *Biochem. Z.* 207, 405-8 (1929).—A dialyzer and an extn. app. for use at temp. below the boiling temp. of the extracting fluid are described. S. MORGULIS

Notes of the laboratory. III. New tubes for cataphoresis. F. VLÈS. *Arch. phys. biol.* 6, 139-40 (1927).—Tubes for cataphoresis are described, which permit perfect asepsis and the use of larger quantities of liquid than in the usual tubes. A. E. M.

Two new laboratory revolving furnaces. FR. HEINRICH. *Chem. Fabrik* 1929, 173-4; cf. TAFEL, *C. A.* 22, 2495. J. H. MOORE

Batch classification in the laboratory. A. W. FAHRENWALD AND CLARENCE THOM. Bur. Mines, *Repts. of Investigations* No. 2924, 5 pp. (1929).—A batch lab. classifier and elutriator designed for use in conjunction with such app. as ball mills and flotation machines is described and illustrated. An application of the app. to grinding studies is given and preliminary data furnish some insight into the relation of power consumption, and fineness of grinding in closed-circuit operations. Locked lab. closed-circuit tests of this kind are probably more efficient than on a com. scale. In prep. samples for lab. flotation tests, this procedure is to be recommended over the usual method of putting the charge in a mill and regulating the grinding time to give the "mesh through" product. W. H. BOYNTON

Artificial resin as material for the construction of chemical apparatus. EMIL KALMAN. *Chem. Fabrik* 1929, 169-70.—Notes on the properties and uses of Haveg (*C. A.* 19, 3039; 20, 3363). J. H. MOORE

Metallic materials of construction for chemical engineering equipment. EVERETT P. PARTRIDGE. *Ind. Eng. Chem.* 21, 471-6 (1929).—A brief but complete review of the more important types of metals and alloys in use at the present time. The most essential data of each group are listed and the suitability of each group for certain fields of service is indicated. FRANK V. JOHNSON, JR.

Vessel with walls or jackets of wood or similar substances and bottoms of metal. ADOLF HARTZ. *Chem. Fabrik* 1929, 193-4.—Cuts and directions for constructing such vessels are given. The bottom may be heated by direct firing, or by steam, etc., while the walls reduce the amt. of radiation. J. H. MOORE

A design of a low-voltage x-ray tube. ELMER DERSHEM. *J. Optical Soc. Am.* 18, 127-30 (1929).—An x-ray tube for the study of x-rays of long wave length is described. It can be readily dismantled for cleaning or changing of targets or filaments. The property utilized in designing the tube is that, when working with rarefied gases, for given pressures, a much greater potential is required to produce a spark discharge if the distance between the electrodes is somewhat less than the mean free path of the atoms or mols. of the gas than is the case if the electrodes are more widely spaced. For air at pressures from 0.002 to 0.01 mm. Hg, the spacing is  $1\frac{1}{2}$  inch. For 0.01 mm. Hg the breakdown potential is 20 kv., higher potentials being required for lower pressures. A diagram of the tube is shown, and the method of assembly and some points relative to its operation are given. L. L. QUILL

Lenard x-ray tube with glass window. C. M. SLACK. *J. Optical Soc. Am.* 18, 123-6 (1929).—A glass window has been designed to be used on Lenard tubes, which ordinarily have thin Al-foil windows. Windows 2.5 cm. in diam. and 0.0005 cm. thick have been very satisfactory. The windows are constructed by drawing in the end of glass tubing to form a bubble, the glass having been previously thinned at this point. Heat cond., energy losses in the window, the cracking of the windows by electrostatic discharges, etc., are mentioned briefly. An attempt is also being made to apply the glass window to oscillographs. L. L. QUILL

A device for stirring within a sealed container. LEONOLD SCHNEIDER. *J. Chem. Education* 6, 947-8 (1929). R. H.

**Rational crucible tongs for analytical use.** LUDWIG RAMBERG. *Svensk Kem. Tid.* 41, 78-9(1929).—The prongs of the crucible tongs (old style) are replaced by Ni wires, 2 mm. in diam. These finer prongs are so bent that when closed and not grasping an object they pass one another. When a crucible is held one prong touches the crucible at one point and the other at 2, and the spring of the wire is sufficient to hold the object firmly but not so strong as to dent thin Pt ware. Two forms are shown in a photograph. A. R. ROSE

**A new apparatus for the determination of water by means of a difficultly combustible heat carrier.** FRITZ FRIEDRICHS. *Chem.-Ztg.* 53, 287(1929).—The substance is distd. with  $C_2H_5Cl_4$ , the distillate passing through a bulb on the lower end of a buret into which the  $H_2O$  rises and is measured. J. H. MOORE

**Apparatus for visual conductivity titrations and conductivity measurements.** O. PFUNDT. Univ. Göttingen. *Chem. Fabrik* 1929, 184-6.—Descriptions of and operating directions for app. in which the telephone is replaced by a galvanometer, which gives direct readings, with references and 5 cuts. J. H. MOORE

**An apparatus for conductivity measurements in very small volumes of fluid.** IGOR REMEZOV. State Institute for Postgraduate Med., Leningrad. *Biochem. Z.* 207, 66-79(1929).—A microelectrode is described by means of which cond. can be measured accurately in as little as 0.05 cc. of fluid. This is accomplished with the aid of amplifying tubes. S. MORGULIS

**Improved field equipment for the determination of  $p_H$ .** E. HURWITZ and L. S. KRAUS. Sanitary District of Chicago. *Eng. News-Record* 102, 704(1929).—An extremely compact comparator for detg.  $p_H$  in the field, employing Clark's indicators and buffer solns., has been developed. A complete set of color standards for the  $p_H$  range 1.8-9.2, indicators and all equipment necessary are contained in a case  $9 \times 6 \times 8\frac{1}{2}$  in. The standards are sealed in Pyrex glass tubes about 11 cm. long with bore of approx. 4 mm. and capacity of 1 cc., mounted on chalk-white celluloid cards. The detn. is made by pipetting 1 cc. of the unknown soln. into a depression in a spot plate, adding 1 drop of indicator, mixing thoroughly, drawing liquid back into the pipet (which is made of same tubing as the standards) and comparing with the standards. R. E. THOMPSON

**Fractional distillation analyses.** W. J. PODBIELNIAK. *Refiner Natural Gasoline Mfr.* 8, No. 3, 55(1929).—A simplified app. of the type developed by P. and E. H. Leslie at the Univ. of Michigan in 1925-6 for gas analysis by the fractional distn. of the liquefied gas is described. The app. is claimed to be simple, compact and adaptable to routine use in industrial labs. by operators of ordinary training. M. B. HART

**Gas testing.** A. SANDER. *Z. Ver. deut. Ing.* 73, 531-8(1929).—Descriptions of app. for gas-testing, methods of use and calcs. involved are given in full. Included are the Junker gas calorimeter (old and new types), Graefe, Dommer and Strache-Löffler calorimeters, and the recording calorimeter "Union" (likewise designed by Dommer); sp. gr. app. of the Bunsen-Schilling, Zipperer, Simmance and Abady, "Union" types; pressure meters; gas analysis app. such as Brüggemann's, the Gasinstitut Karlsruhe, etc.; Raupp app. for  $H_2S$  detn.; Kattwinkel app. for detn. of  $C_2H_4$  in gas, methods for detn. of total S,  $NH_3$ , etc. Post-war economic conditions have made it imperative that closer control of gas quality be maintained than was the case earlier than 1918. W. C. EBAUGH

**Sensitive instrument for low pressure.** ANON. *Arch. Wärmewirt.* 10, 104(1929).—This device, for showing vacuum in plant app., consists of a barometric manometer bent in the form of a nearly complete circle, and balanced. Changes in the Hg levels cause the manometer to swing, and an attached hand shows the abs. pressure. ERNEST W. THIELE

**The construction and calibration of a sensitive form of Pirani gage for the measurement of high vacua.** L. F. STANLEY. Royal Coll. of Science. *Proc. Phys. Soc. (London)* 41, 194-203(1929).—The app. "consists of manometer and a compensator of identical construction placed in the opposite arms of a Callendar-Griffiths bridge. Each comprises, essentially, a loop of 10 cm. of Pt wire 0.001 in. diam., together with a compensating loop of 2 cm. of the same wire. The symmetry of the circuit makes errors due to thermoelec. effects very small. . . . The gage follows variations of pressure with considerable rapidity, and its range of measurement is from  $2 \times 10^{-3}$  mm. to  $4 \times 10^{-4}$  mm., approx." The paper contains a "Note on the accuracy of the ordinary type of McLeod gage." J. H. MOORE

**The influence of air in apparatus for measuring the pressure and quantity of gases lighter than air, and in the lines leading to them.** KARL LÖNNERCKE. *Feuerungstech.* 16, 268-72(1928).—L. points out that where the measuring app. lies much lower than the line, air in the connecting lines may cause serious errors. ERNEST W. THIELE

**Determination of the pressure on containers filled with liquid ammonia.** R. NITZSCHMANN. *Chem. App.* 16, 81-2(1929).—Mathematical formulas, with 3 tables giving data up to 25.63 atms. over a temp. range from  $-30$  to  $+60^{\circ}$ . J. H. M.

**Electrical instruments used in the measurement of flow.** W. H. PRATT. *J. Am. Inst. Elec. Eng.* 48, 142(1929). H. R. MOORE

**A farewell word on the Venturi meter.** CLEMENS HERSCHEL. *Eng. News-Record* 102, 636-7(1929).—A brief discussion by the inventor of this minimum-loss-of-head meter, which has been unapproached for precision of measurement since developed over 40 years ago. The practice of shortening the meter tube by increasing the cone angle of the discharge tube destroys one of the greatest advantages of the instrument, namely, that of regaining the head in full. The long taper of the discharge tube also delivers the water with less turbulence and produces a more perfect "differential." Venturi tube forms can be built of wood or concrete (with exception of throat piece) inside standard pipe or penstock sections. Such meters have given reliable service for years. R. E. THOMPSON

**The optical chronograph.** HANS RUMPF. *Z. ges. Schiess- u. Sprengstoffw.* 24, 55 7, 99-100(1929).—This app. comprises an oscillograph with unusually high velocity of sensitized paper or film (up to 70 m./sec.). It is applicable to measurement of velocity of detonation of explosives, of velocity of projectiles, of duration and intensity of flame, of the study of coal dust explosions, etc. The instrument and its method of use are described. C. G. STORM

**A modified Wilson-Kern extractor.** H. B. MERRILL. A. F. Gallun & Sons, Milwaukee, Wis. *J. Am. Leather Chem. Assoc.* 24, 244-5(1929).—One of the original 3 glass parts connected by ground joints has been eliminated. The modified app. is more rugged, cheaper and easier to regulate than the original form. H. B. M.

**Determination of the specific gravity of refractory materials.** E. KUEHN. *Feuerfest* 1929, No. 1, 5.—A *volumoscope* is described by means of which more than 30 sp. gr. detns. can be made in 1 hr. The app. is filled with 200 g. of material, vacuum is produced, and by simple operation of the hand true sp. gr. can be read off. The material being tested comes into contact with air only. E. I. S.

**New apparatus for measuring thermal expansion of refractory materials at  $1600^{\circ}$ .** K. ENDELL. *Feuerfest* 1929, 3-4; cf. *C. A.* 22, 3027. E. I. S.

**Summary of recommendations on ordinary commercial cylinders for the storage and transport of the so-called "permanent" gases.** H. C. H. CARPENTER, et al. Dept. Sci. Ind. Research. *Gas Cylinders Research Comm.* 1929, 7 pp.—A reprint of the first report of the Gas Cylinders Research Comm. published in 1921 incorporates revisions representing alterations of wording or changes in the substance of the recommendations. Plain C steel of seamless tubing with the following compn. should be used: C 0.43-0.48%, S < 0.045, P < 0.045, Mn 0.5-0.9%, Si not to exceed 0.3%. Twenty-two recommendations are made covering: materials of the cylinder, manuf., testing of completed cylinders, working pressures, fittings, painting and periodical examn. W. H. BOYNTON

**Characteristics of radio-receiving tubes.** L. SUTHERLIN AND C. B. UPP. *Elec. J.* 26, 146-52(1929).—Twenty-four figs. C. G. F.

**Fire sprinkler systems in the chemical industry.** JOSEF IMMERSCHITT. *Chem. Fabrik* 1929, 157-8. A. WHITE

#### Optical temperature measurement in furnace (AECKERLEIN) 2.

WAGNER, BERNHARD: Tabellen zum Eintauchrefraktometer. Including supplement: Die Refraktometrie der Milch. Edited by SIMON ROTHENFUSSE. Jena: Carl Zeiss. 162 pp. Linen; M. 40.50.

**Thermionic cathodes.** WESTINGHOUSE ELEC. AND MANUF. CO. Fr. 647,021, Jan. 12, 1928. The cathodes are made from an alloy contg., e. g., Ni 80, Co 20, Fe 7.5 and Ti 2.5 parts. The electron-emitting coating contains BaO and SrO.

**Vessel for effecting chemical reactions.** OTTO ROLAND. Ger. 475,127, Aug. 13, 1927. The principal feature is a rotating hollow worm, to the interior of which the reagents are supplied. The reagents pass to the bottom of the worm and thence to the space between the worm and the walls of the vessel; they are then conveyed upward by the worm in close proximity to the walls, which carry heating or cooling pipes. The reagents may be circulated as often as desired, and means are provided for admitting gases to the interior of the worm. The manuf. of AcOH from  $(\text{AcO})_2\text{Ca}$  and  $\text{H}_2\text{SO}_4$  is referred to.

**Tintometer with superposed color screens.** O. ROSENHEIM, E. H. J. SCHUSTER and TINTOMETER, LTD. Brit. 299,194, Oct. 31, 1927. Structural features.

**Filters.** ALBERT SCHREMPF. Fr. 651,642, Mar. 23, 1928. Method of mounting filters of perforated cloth in a cell for the purification of air, gas, vapors, oil, etc.

**Air filter.** GENERAL AIR FILTERS CORP. Fr. 650,821, Mar. 13, 1928. An air filter of the type in which the air is caused to pass in a zig-zag path over plates coated with a viscous fluid is described.

**Continuous rotary drum filter.** JERONIMO D. COMPAIN. U. S. 1,712,258, May 7. Structural features.

**Apparatus for dissolving, filtering, or washing materials.** HERMANN FRISCHER. U. S. 1,711,638, May 7. A rotary sieve or filter drum is mounted within a vat or tank and carries stirring devices on its periphery.

**Apparatus for separating impurities from gas or air by conical baffle plates.** ESTATE OF HANS E. THEISEN. Fr. 650,633, March 9, 1928.

**Apparatus for extracting solids from gases by centrifugal deposition.** JAMES GORDON & Co., LTD. Fr. 647,813, Nov. 21, 1927.

**Bubble cap and tray construction for fractionating or rectifying apparatus.** FAYETTE P. RISDON (to Texas Co.). U. S. 1,711,656, May 7.

**X-ray apparatus.** SIEGMUND LOEWE. Ger. 475,276, Mar. 6, 1919.

**Vacuum tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 651,345, March 2, 1928, and Fr. 651,362, March 8, 1928. Method of mounting the electrodes.

**Vacuum tubes.** JEAN B. J. M. ABADIE. Fr. 651,204, Aug. 31, 1927. Vacuum tubes contg. rarefied gases, such as Ne, A, He, etc., have electrodes of Pb, Bi, Tl, Sn or Cd instead of Hg.

**Electric vacuum discharge tubes.** W. GERMERSHAUSEN. Brit. 299,431, Oct. 26, 1927. An incandescent cathode may be formed of Ni wire with a surrounding winding of W or Ir wire, plated with Ni and then activated by the formation of a Ba-Ni alloy. Wire already activated may be used for the winding, if desired, and the assembly then plated with an activated metal.

**Electric discharge tube.** FRANZ SKAUPY (to General Electric Co.). U. S. 1,712,407, May 7. A sealed container filled with an attenuated inert gas such as A or Ne contains non-alk. electrodes, which may be formed of Fe or W and which consist of fine wire mesh free from occluded active gases so that a glow discharge may be operated between the electrodes at voltages of about 100 volts; the area of the electrodes is great enough to permit of the indefinite continuance of the glow discharge at such voltages.

**Electron discharge tubes.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 650,360, Feb. 27, 1928.

**Electron discharge tube.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Fr. 650,441, Mar. 5, 1928.

**Electric discharge tubes.** NAAMLOOZE VENNOOTSCHAP PHILIPS' GLOEILAMPEN-FABRIEKEN. Fr. 650,700, Mar. 9, 1928.

**Thermionic valves.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 651,405, Mar. 14, 1928.

**Mixing machine for powders.** ERNST KUBISCH. Ger. 475,251, Aug. 1, 1926.

**Dispersion mill.** THE ANODE RUBBER CO. (ENGLAND), LTD. Fr. 650,673, Feb. 20, 1928. A mill is described for bringing solids into dispersion in liquids, the liquid contg. the solid to be dispersed and protective colloids being agitated with hard grinding masses, which are of different sizes and rounded but not spherical.

**Grinding mill.** ANDREAS INGENIEUR-BÜRO UND MASCHINENBAU-GES. M. B. H. Ger. 475,149, Mar. 27, 1928.

**Grinding apparatus for mineral substances.** SOC. ANON. DES ANCIENS ÉTABLISSEMENTS RAYMOND FRÈRES. Fr. 650,853, Mar. 14, 1928.

**Disintegrating mill with internal winnowing means.** ERNST C. LOESCHE. Ger. 475,165, Feb. 13, 1925.

**Drying and disintegrating drum for moist materials.** I. G. FARBENIND. A.-G. (Oskar Spengler, Otto Beurlen and Rudolf Weidenhagen, inventors). Ger. 471,298, Feb. 17, 1926.

**Vertical drying chambers.** MINES DOMANIALES DE POTASSE D'ALSACE. Fr. 651,058, Mar. 20, 1928. The greater part of the warm gases are introduced at the top and the rest at the bottom, and are withdrawn at an intermediate point.

**Apparatus for drying pasty materials.** I. G. FARBENIND. A.-G. (Albert Jüngst, inventor). Ger. 475,158, May 6, 1927. The material is taken up on an endless band.

which carries it through a smoother or distributor and then over a heated roller. Cf. C. A. 23, 1314.

**Drying or destructive distillation apparatus.** LUDWIG HONIGMANN. Ger. 466,925, Nov. 6, 1925. The finely granular material to be treated travels along the lower half of a container, the upper half of which is traversed by a current of hot gas. Heat is conveyed to the material by conductive perforated plates mounted on a central rotary shaft.

**Condenser for cracked oil or other vapors.** WILLIAM HILDEBRANDT (to Gasoline Corp.). U. S. 1,712,825, May 14. Structural features.

**Cooler for flowing liquids (applying transverse stream of air).** FRANZ LEITNER. Ger. 475,110, July 26, 1923. Addn. to 402,630.

**Device for cooling liquids with solid carbon dioxide.** LOUIS W. HASSENSALL. U. S. 1,712,701, May 14. The solid refrigerant is placed in a container immersed in the liquid to be cooled and gas evolved from the refrigerant passes through a bent tube and is discharged into the liquid.

**Cooling pan for pitch, asphalt, etc.** GES. FÜR TEERVERWERWERTUNG M. B. H. and ADOLF SPILKER. Ger. 475,028, Feb. 8, 1927.

**Apparatus for concentrating solids by fluid currents.** ALBERT H. STEBBINS. U. S. 1,714,589, May 14. Structural features.

**Furnaces.** JAMES GORDON AND CO. Fr. 650,330, Jan. 11, 1928. Means for regulating the fuel supply for furnaces, such as those using gases from blast furnaces where the supply is very irregular, are described.

**Furnaces.** RUDOLF HAAS and MANFRED SENG. Ger. 474,076, Feb. 19, 1921. Grate furnaces into which a supplementary supply of powd. fuel is blown are constructed or operated so that the powd. fuel is blown in counter current to the fuel on the grate.

**Coal-dust furnace.** JULIUS HAACK. Ger. 475,245, May 9, 1924. Addn. to 467,933 (C. A. 23, 552).

**Shaft furnace.** W. SCHWARZ & Co. Ger. 475,212, Jan. 13, 1928. A shaft furnace for calcining or sintering powd. materials has a no. of coaxial chambers into each of which only fuel or only the material to be treated is fed, the fuel and the material being blown in at the top of the furnace. For instance, 3 chambers may be provided, the material being supplied to the middle one and the other chambers having seals at their lower ends designed to hinder contact of the hot gases with the material leaving the furnace.

**Air heater for furnaces.** WILLIAM M. CONNERY. Ger. 475,493, Aug. 5, 1924.

**Air heater for furnaces.** EUGEN HABER. Ger. 475,494, Feb. 26, 1927.

**Apparatus for automatically supplying oxygen to furnaces in gradually increasing and decreasing quantity.** ARTHUR O. HIGINBOTHAM (one-half to William A. Weigle). U. S. 1,711,943-4, May 7.

**Electric system (depending on steam flow or pressure) for regulating combustion in boiler furnaces.** A. G. S. SANDISON and ELECTROFLOW METERS CO., LTD. Brit. 299,198, Nov. 4, 1927. Numerous structural details are described.

**Water-cooled protective wall for furnace chambers.** SCHMIDT'SCHE HEISSDAMPF-GES. M. B. H. Ger. 475,438, April 24, 1927.

**Gas burner.** H. BANSSEN. Brit. 299,217, Dec. 5, 1927.

**Gas burner.** AUGUST J. HARTFIELD. U. S. 1,712,885, May 14.

**Gas burner.** OTTO B. KIBLE. U. S. 1,711,794, May 7.

**Gas burner.** BERT THORNTON. U. S. 1,712,410, May 7.

**Mechanically regulated gas burner.** FIRMA AUG KLÖNNE. Ger. 475,075, Feb. 15, 1928.

**Gas-burner construction for furnaces.** CARL W. GIBSON. U. S. 1,712,881, May 14.

**Burner construction suitable for liquid fuels.** JOSEPH BROCK. U. S. 1,712,326, May 7.

**Liquid-fuel burners.** SIDNEY E. MAJOR and EMRYS F. BAKER. Australia 12,471, Mar. 24, 1928.

**Burners for liquid fuel.** PAUL LINKE. Fr. 651,335, Feb. 22, 1928.

**Burners for heavy oils.** WALTER OSTHOFF. Fr. 651,248, Mar. 9, 1928. The oil is considerably cooled on its way from the point at which it is vaporized to the mouth of the burner.

**Oil-burner control.** ALLGEMEINE ELEKTRICITÄTS-GES. Ger. 475,492, Oct. 14, 1927. Elec. circuits including a photoelec. cell are described whereby the supply of fuel is automatically varied in accordance with the intensity of the flame, and is discontinued when the flame is extinguished.

**Gasifying means for gasoline or oil burners.** JOSEPH WELTNER. Fr. 650,654, Jan. 17, 1928.

**Apparatus for heat treatment of oils or other liquids.** WILLIAM WINSHIP. U. S. 1,712,372, May 7. Vertical open-ended tubes completely submerged in the liquid under treatment are formed of metal or other suitable material of high elec. resistance; the tubes while contg. and surrounded by the liquid are heated by elec. current. Various other structural details of the app. are described.

**Heat exchanger.** LA MONT CORP. Ger. 475,050, Oct. 20, 1926.

**Heat-exchange apparatus suitable for heating air by use of combustion gases.** GREGORY D. MANTLE (to Mantle Engineering Co.). U. S. 1,712,892, May 14. Structural features.

**Heat-exchange coil suitable for use with heating or cooling apparatus.** JOHN STRINDLUND (to G. D. Jenssen Co.). U. S. 1,713,456, May 14. Structural features.

**Acetylene generator.** PATRICK McDONALD. U. S. 1,712,392, May 7.

**Cartridge for generating acetylene or other gases.** A. P. STRERR. Brit. 299,400, Oct. 25, 1927. Carbide or other gas-generating material is enclosed in an envelope of woven or perforated material, which may be rendered hygroscopic and which may be further protected by an outer covering. Various details of manuf. are specified.

**Apparatus for classifying coal, ores, etc.** ANTOINE FRANCE. Fr. 650,971, Mar. 17, 1928.

**Cooling means for powdered-fuel combustion chambers.** DEUTSCHE BABCOCK & WILCOX DAMPFKESSEL-WERKE A.-G. Ger. 475,228, Aug. 20, 1925.

**Apparatus for pumping fuel oils or other viscous materials.** GUNNAR C. ENGSTRAND (to Salvage Process Corp.). U. S. 1,712,694-5, May 14.

**Floot construction for preventing evaporation from the surface of oil in storage tanks.** IVAN R. AFONIN. U. S. 1,712,321, May 7.

**Evaporator for liquefied gases.** JOHANNES ZÜSR. Swiss 129,292, Dec. 19, 1927. Liquefied gas is contained in a vessel with a heat-insulating jacket outside to prevent too rapid evapn. when placed in a bath. The vessel has a gas-tight cover, and a delivery tube of small cross-section.

**Apparatus for evaporation and concentration of solutions of saline or other substances.** GEORGES H. PASSELECO. U. S. 1,711,614, May 7. An app. is described comprising an evapg. chamber partitioned into sections all communicating with a common vapor outlet and connected in series by conduits to provide a thermo-siphonic circulation system.

**Liquid-degasifying attachment for measuring pumps.** MARTINI & HÜNEKE MASCHINENBAU-A.-G. Ger. 475,444, Mar. 12, 1927.

**Apparatus for indicating and regulating the density of gaseous mixtures.** SMOOT ENGINEERING CORP. Fr. 651,225, Jan. 30, 1928.

**Gas washer suitable for extraction of hydrocarbons from gas and vapor mixtures.** P. M. SALERNI. Brit. 299,481, April 26, 1927. The gas and vapor mixt. together with oil or other absorbent is forced along spiral passages of an app., various structural details of which are described.

**Gas scrubber with rotating sprays.** GUSTAVE FAST. U. S. 1,713,175, May 14. Structural features.

**Cleaning digesters.** GUSTAV ULLMANN. Ger. 475,119, June 6, 1926. Digesters operating under pressure are cleaned by spraying in water or other liquid at the time when the pressure is released.

**Apparatus for producing foam by passing air through a saponin solution, etc.** G. M. THOMSON. Brit. 299,242, Jan. 31, 1928. Various structural details are specified.

**Bubble tray construction for column stills, etc.** J. PRIMROSE and H. R. SWANSON (to Power Specialty Co.). Brit. 299,479, May 5, 1926.

**Abrasion apparatus for determining the wearing qualities of rubber tire treads, shoe soles, linoleum, or other materials.** IRA WILLIAMS (to Grasselli Chemical Co.). U. S. 1,711,866, May 7. An app. is described having a rotating abrading device against which the sample tested is held. The loss of material from the sample per unit of powder used for operating the abrading device is measured.

**Thermoelectric elements.** WALTER KÖNIG. Ger. 475,338, July 18, 1928. In attaching lamelliform thermoelec. elements to a central heating tube of ceramic or other material, the tube is externally enameled and the elements are set in suitable contact in the enamel layer and heated so that a firm union is obtained.

**Temperature switch.** AUDIFFREN SINGRÜN KÄLTE-MASCHINEN A.-G. Swiss 129,704, Dec. 27, 1927. A U-tube has a contact terminal in each limb and an elec. conducting liquid below them. One limb is connected to a closed tube contg. an

expansion liquid, which detts. which of the terminals is in contact with the conducting liquid.

"Two-temperature" thermostat. FRED W. POWERS and MORTON O. SNEDIKER (to Power Regulator Co.). U. S. 1,712,841, May 14. Structural features.

Thermostatic valve-control device. ADOLPH O. NELSON. U. S. 1,711,901, May 7. Structural features.

Thermostatic control for gas valves. JAY H. SMITH. U. S. 1,712,313, May 7. Structural features.

Thermostatic and other control devices for oil-burning steam-generating furnaces. MARC RESEK (to Perfection Stove Co.). U. S. 1,712,737, May 14.

Compensation method for measuring small currents. R. JAEGER. *Z. Physik* 54, 152(1929).—J. compares his method (C. A. 23, 1794) with an earlier one by Rutherford and Chadwick (C. A. 6, 2357). GEORGE GLOCKLER

A novel method for optical temperature measurement in furnaces. G. AECKERLEIN. Bergakad., Freiberg. *Z. tech. Physik* 10, 129-36(1929).—Optical temp. measurements are correct only if sufficient reflected or transmitted radiation is added to the temp. radiation of the focused object to make its radiation equal to that of a black body. The correction method here expounded consists of measuring the temp. optically (Holborn Kurlbaum pyrometer, 650 $\mu$  glass filter) by focusing on 2 faces of the object which are at an obtuse angle to each other, then analyzing from the 2 measurements the proper and the foreign radiation (sharp and diffuse reflection), thus arriving at the true temp. of the object. The reflecting-power curves of the material are supposed to be known. For the example of "Korunite" (80% Al<sub>2</sub>O<sub>3</sub>, m. 2000°) the method was worked out exptly.; its reflecting power was detd. at various angles of incidence photometrically. For the diffuse reflection (intensity  $I_d$ ) the value of  $(I_d/I_a)(1/\cos \epsilon)$  was  $1.075 \pm 0.082$ ; for the angle of incidence  $\epsilon$  from +20° to -60° and reflection angles up to 70° the coeff.  $d$  was found to be 45.9%. This coeff. appeared not to change on heating. For the direct reflection the coeff.  $r$  was between 9.2 and 10.2% at a 70°, 2.5 to 3.1% at a 40° angle, and depended on temp. Focusing a korunite face in a furnace from 2 angles (40° and 70° with normal) gave measured values of the temp.  $t_1 = 1036.3^\circ$  and  $t_2 = 1039^\circ$ , resp.; from these the intensities  $I_1$  and  $I_2$  are calcd. by  $I = \epsilon_1 \lambda^{-5} e^{-\alpha/\lambda T}$ ; the difference  $\Delta I$  is related to the intensity of the proper radiation of the object by  $I_a = I_1 A_1 - [(d + r_1)/(r_2 - r_1)] A_1 \Delta I$  with  $A_1 = 1 - d - r$ . From  $I_a$  it follows that the actual temp. of the material is  $t_a = 1013^\circ$  as compared with a value of 1019.5° from direct thermoelectric measurement. An energy balance of the various radiation effects is added. B. J. C. VAN DER HOEVEN

**The laws of periodicity. IV.** P. PETRENKO-KRITCHENKO, V. OPOTZKII, M. D'YAKOVA AND A. LOSOVOI. *Ber.* 62B, 581-8(1929); cf. *C. A.* 22, 3574; 23, 2092.—This is a further attempt to show regular relations for the activity of aliphatic halides from the reaction rates with colloidal Ag, KOH, piperidine and AgNO<sub>3</sub>.

A. FLEISCHER

**The structure of the noble metals.** TÖM. BARTH. *Metallwirtschaft* 7, 413-5 (1928).—If the light noble metals be arranged in the order Ru-Rh-Pd-Ag, and the heavy ones in the sequence Os-Ir-Pt-Au, *i. e.*, in the order of their at. nos., it is found that the first member of each series has a hexagonal lattice structure and the other 6 have the cubic form. From the at. wts. of Ag and Au one might think that the latter was larger than the former, but this is not the case; the Au atom is put together more compactly than the Ag atom. The same thing applies to the other 6 metals. Radii of the given atoms are in the ratios 1.30:1.34:1.37:1.44 and 1.31:1.35:1.38:1.44 for the 2 series. Metals in the first series are more easily compressed than those in the second. At a pressure of 14,000 atms. and ordinary temp. the at. vols. of Ag and Au become alike. At high pressure and low temp. Ag is smaller than Au; at smaller pressure and higher temp. the reverse is true.

W. C. EBAUGH

**The influence of elements on the polymorphism of iron.** ALBERT HEINZEL. Kaiser Wilhelm Inst. Eisenforschung, Düsseldorf. *Z. tech. Physik* 10, 136-7(1929).—The boundaries of the field of  $\gamma$  iron of face-centered structure (normally from 906° to 1401°) are influenced by admixts. Elements of the 7th, 8th, 1st and 2nd groups of the periodic system, if sol. in Fe and closely related to Fe physically and chemically, generally widen the range up and downward, *e. g.*, Mn. A narrowing of the range of  $\gamma$  Fe and eventually a disappearance of the  $\gamma$  phase results from addn. of elements of the 3rd to 6th group of the periodic system (*e. g.*, with V there is no  $\gamma$  Fe when V exceeds 1.1%), these being unrelated to Fe even if sol. in it. An exception to the last rule is found in N and C. All elements of large atom radius, alkali and earth alkali metals, Hg, Pb, Tl, Bi and Ag and Cd are insol. in Fe. B. J. C. VAN DER HOEVEN

**The electrical resistance of alloys under pressure.** C. W. UFFORD. Harvard Univ. *Proc. Am. Acad. Arts Sci.* 63, 309-28(1928).—The pressure and temp. coeffs. of elec. resistance were detd. from atmospheric to 12,000 kg./cm.<sup>2</sup> hydrostatic pressures for 3 series of alloys: Li-Sn, Bi-Sn, Ca-Pb; and one alloy of Ca and Mg with 10 atomic % Mg. These 3 series were chosen because the resistance of Li, Bi and Ca increases with pressure, and that of Sn and Pb decreases with pressure. A large variation of pressure coeff. with change in compn. is thus obtained. The relative change of resistance of the 3 series may be correlated with the changes in structure according to equil. diagrams. Putting a foreign metal into a pure one increases the pressure coeff. of resistance of the pure metal algebraically, and increasing the hydrostatic pressure has the same effect. It seems probable that the cond. of a metal depends on the geometrical configuration of the crystal lattice. These expts. do not, as was hoped, give a basis for explaining the positive pressure coeffs. of resistance of Li, Ca and Bi.

M. W. SEYMOUR

**The effect of pressure on the resistance of three series of alloys.** P. W. BRIDGMAN. Harvard Univ. *Proc. Am. Acad. Arts Sci.* 63, 329-45(1928).—The pressure and temp. coeff. of elec. resistance and the sp. resistance at 30° have been detd. for 3 series of alloys: Fe-Co; Fe-Ni; Cu-Ni. The results support Ufford's generalization (cf. preceding abstr.) that the effect of adding a small amt. of a foreign metal to a pure metal is to increase algebraically its pressure coeff. of elec. resistance. His conclusion that the effect of adding a foreign metal is equiv. to an increase of external pressure is shown not to be true for the Fe-Ni series. In this series, the addn. of Ni or Fe to the other pure metal distends the lattice, as a decrease in pressure would do. The same is true for the addn. of Co to Fe, and probably for the addn. of Cu to Ni, though the effect is smaller and uncertain. Greater regularity is found in the curves for sp. resistance and pressure coeff. of resistance, plotted against compn., than in temp. coeff. of resistance. The correlation between high sp. resistance and positive pressure coeff. of resistance is explained by assuming that high sp. resistance is caused by a lack of perfect fit between adjacent atoms in the crystal lattice and that the lack is accentuated by increased pressure.

M. W. SEYMOUR

**The compressibility and pressure coefficient of resistance of zirconium and hafnium.** P. W. BRIDGMAN. Harvard Univ. *Proc. Am. Acad. Arts Sci.* 63, 347-50(1928).—A Zr wire about 0.050 cm. in diam. and 14 cm. long was used for resistance measurements, and a piece of Zr 2.7 cm. long and 3 mm. in diam. was used to det. compressibility. The compressibility at 30°,  $-\Delta V/V_0 = 10.97 \times 10^{-7}p - 7.44 \times 10^{-12}p^2$ . At 75°,  $-\Delta V/V_0 = 11.06 \times 10^{-7}p - 7.80 \times 10^{-12}p^2$ . Pressures are in kg./cm.<sup>2</sup> The

pressure coeff. of resistance at  $30^\circ$ ,  $\Delta R/R(0 \text{ kg.}, 30^\circ) = -4.31 \times 10^{-7}p + 6.5 \times 10^{-12}p^2$ . At  $75^\circ$ ,  $\Delta R/R(0 \text{ kg.}, 75^\circ) = -6.01 \times 10^{-7}p + 5.8 \times 10^{-12}p^2$ . The sp. resistance at  $30^\circ$  is  $49.2 \times 10^{-6}$  and the mean temp. coeff. of resistance between  $0^\circ$  and  $100^\circ$ , 0.00403. A piece of Hf about 2.6 cm. long and 2 mm. in diam. was used for all measurements. At  $30^\circ$ ,  $-\Delta V/V_0 = 9.01 \times 10^{-7}p - 2.37 \times 10^{-12}p^2$ . At  $75^\circ$ ,  $-\Delta V/V_0 = 8.81 \times 10^{-7}p - 2.37 \times 10^{-12}p^2$ . At  $30^\circ$ , the av. deviation from a smooth curve was 1.7% of the max. pressure effect, and at  $75^\circ$ , 2.0%. It is, therefore, not certain that compressibility at  $75^\circ$  is less than at  $30^\circ$ . The pressure coeff. of resistance at  $30^\circ$ ,  $\Delta R/R(0 \text{ kg.}, 30^\circ) = -10.0 \times 10^{-7}p$ . The sp. resistance at  $30^\circ$  is  $35.7 \times 10^{-6}$ , and the mean temp. coeff. between  $0^\circ$  and  $100^\circ$  is 0.00398.

M. W. SEYMOUR

**Theory of concentrated solutions. VI. Application of thermic analysis to the determination of freezing curves of binary mixtures of organic compounds melting at low temperature.** JEAN TIMMERMANS. Univ. Brussels. *Bull. soc. chim. Belg.* 37, 409-23 (1928).—The freezing curves of 20 mixts. of org. compds. were exptly. detd. The compds. were specially purified by the "Bureau des Etalons physico-chimiques" and the results have an unusual degree of accuracy. The systems investigated were:  $C_6H_6 + C_6H_{14}$ ,  $C_6H_6 + CHCl_3$ , cyclohexane + methylcyclohexane, cyclohexane +  $C_6H_{14}$ , cyclohexane + PhMe, cyclohexane +  $CCl_4$ , cyclohexane +  $CHCl_3$ ,  $(CH_2Br)_2 + EtBr$ ,  $(CH_2Br)_2 + PhNH_2$ ,  $PhNO_2 + CS_2$ ,  $PhNO_2 + AcOEt$ ,  $PhNH_2 + CCl_4$ ,  $PhNH_2 + PhMe$ ,  $PhNH_2 + Me_2CO$ ,  $CCl_4 + CHCl_3$ ,  $CCl_4 + CS_2$ ,  $CCl_4 + Me_2CO$ ,  $CHCl_3 + C_6H_{14}$ ,  $CHCl_3 + PhMe$ ,  $CHCl_3 + CS_2$ . The systems cyclohexane + methylcyclohexane, cyclohexane +  $C_6H_{14}$ ,  $(CH_2Br)_2 + EtBr$  and  $CCl_4 + CHCl_3$  are ideal solns. The systems  $C_6H_6 + CHCl_3$ , PhMe +  $CHCl_3$ ,  $PhNH_2 + Me_2CO$  give addn. compds. A new transformation point at  $-91^\circ$  was found in the case of cyclohexane.

ALBERT L. HENNE

**Passivity.** AGNES M. HASEBRINK. Physikalische Inst., Münster i W. *Z. Elektrochem.* 34, 819-29 (1928).—Cr treated with  $HNO_3$  and heated in N remains active during a few hrs., then becomes passive. If HCl is substituted for  $HNO_3$ , Cr retains its activity as long as it is kept in N. Cr activated in H remains active in this gas. At ordinary temp. N, H and  $CO_2$  do not activate Cr; neither do they passivify Cr activated by scratching. The quantity and the nature of the gases occluded in the metal det. the ease with which it will be activated or passivified. Large amounts of O favor passivification, while H retards it. The O of the atm. passivifies Cr rapidly. I may act as an activating agent, never as a passivifying agent. The potential of Cr or Ni rubbed with emery in an indifferent atm. falls at first, then recovers partially; after repeated rubbings, a const. potential is finally reached, which is lower than the initial one. Mol. O passed through the electrolyte during the electrolysis of Cr raises its potential; the replacement of the O current by a current of molecular N or H hardly affects the potential. Electrolytic H or O has an enormous influence on the potential. The above expts. are regarded as evidences in favor of the O theory of passivification. Sheet iron was electrolyzed in a concd.  $KNO_3$  soln. The results depended on the compn. and treatment of the sheet. Liberation of O or H on the surface of the metal seemed to increase the electrolytic solution, but the action of the gas was only mechanical; underrived small metal splinters and tore them off the sheet. A. L. H.

**New ways and means of atom chemistry.** ERNST BRÜCHE. A. E. G., Berlin. *Naturwissenschaften* 17, 252-4 (1929).—A review of recent work (cf. C. A. 21, 2425; 1722) on the detn. of radii of activity of mols. as related to their phys. structure.

$CO$  and  $N_2$  the curves of effective cross section (measured as sq. cm. per cc. at 1 mm. pressure) vs. velocity of the test electrons (Ramsauer method, *Physik. Z.* 29, 823 (1928)) almost identical, indicating great similarity of phys. structure. Effects in the curves related to their chem. difference are apparent only at the lowest velocities; these effects are due to a difference in dipole character of the mols. The mols.  $N_2$  and  $C_2H_2$  also are similar in phys. respects; the H atoms of  $C_2H_2$  penetrate the electron shell of C and are largely shielded while the C kernels (Lewis' conceptions are used) are loosened as a result. A third pair of physically similar mols. is  $CH_4$  and Kr; evidenced by the shape of their elec. field curves. The chem. similarity in inertia of Kr and  $N_2$  is in no way due to similarity in phys. structure (cf. also *Ibid* 29, 830 (1928); A. 23, 2613).

**Magnetic properties in relation to chemical constitution.** L. C. JACKSON. *Nature* 123, 279(1929).—Lowry and Gilbert (C. A. 23, 2334) state that x-ray analysis indicates that Fe pyrites is a ferrous disulfide  $\text{Fe}^{++}\text{S}^{--}$ . J. finds that magnetic measurements also support the idea that  $\text{Fe}^{++}$  in pyrites has a constitution corresponding to that of Fe in say  $\text{K}_4\text{Fe}(\text{CN})_6$  and not as  $\text{Fe}^{++}$  in  $\text{FeSO}_4$ . Minerals of which  $\text{FeS}_2$  is typical must therefore be classified as coordination compds.

GEORGE GLOCKER

**Crystal structure and ferromagnetism.** O. v. AUWERS. *Physik. Z.* 29, 921-7 (1928).—In an attempt to apply the quantum mechanics of Heisenberg to the phenomena of ferromagnetism, a critical survey is made of the available crystallographic and magnetic data. A possible relation between ferromagnetism and lattice structure is sought by considering the behavior of the elements, a series of binary alloys, and a tertiary alloy. Heisenberg's theory is built up upon a very general basis and the question is raised whether this theory is applicable solely to crystals made up of atoms of only one sort or can be extended to crystals made up of different sorts of "building stones." The importance of a temp. function from which the Curie temp. can be calcd. is emphasized and three possible influences of temp. are mentioned. Several geometrical relations of the at. distances corresponding to the various states of Fe are discussed. It is concluded from these considerations that the key to the understanding of ferromagnetic properties should be sought not in any particular crystal system but rather in its alteration with temp.

W. W. STIFLER

**Ferromagnetic ferric oxide.** E. F. HERROUN AND E. WILSON. *Proc. Phys. Soc. (London)* 41, 100-11(1928).—The results obtained during the past 8 yrs. by various investigators are reviewed in detail. The observations of Sosman and Posnjak that lepidocrocite on dehydration yields a strongly ferromagnetic ferric oxide while goëthite does not, are confirmed. Since every specimen of the former contained 3-4% of  $\text{Mn}_2\text{O}_3$  or  $\text{Mn}_3\text{O}_4$ , it is suggested that this may be an essential constituent of this cryst. form. The mode of prepn. has a great influence on the temp. at which the ferromagnetic oxide is permanently transformed into the paramagnetic form. Tests were made on rectangular bars made by compressing the powdered material, and the results for the different kinds of magnetic ferric oxide are compared with those for Cu and Mg ferrites. Cu ferrite has a higher max. permeability than ordinary pptd. magnetic oxide of Fe but this value is much less than that of the purer native magnetites. The high or low values of the susceptibilities of the  $\text{Fe}_2\text{O}_3$  resulting from the oxidation of several of the native magnetites is attributed to the presence or absence of impurities (particularly Mg) as shown by their analyses.

W. W. STIFLER

**Magnetic susceptibility of the alkaline earth halides.** KURT IKENMEYER. *Ann. Physik* [5], 1, 169-91(1929).—The susceptibilities of 20 halides of the alkalis and alk. earths in aq. soln. were measured by a differential method in which the torsional effect in an inhomogeneous field was observed. Measurements were made at from 4 to 9 concns. The results indicate a linear relation between susceptibility and concn. In some cases the mol. susceptibilities are not in agreement with earlier values. The mol. susceptibility is approx. a linear function of the nuclear charge, as shown by the equation  $-X_m = c_1 z_m + c_2$ , in which  $z_m$  is the sum of the nos. specifying the nuclear charges of the ions,  $c_1 = 8.03 \times 10^{-6}$  and  $c_2 = 8.30 \times 10^{-4}$ . From the values given by this equation, the at. susceptibilities are computed for the various ions, by assuming a purely additive law. It is then found that these results can be represented as functions of the nuclear no. of the ion,  $Z$ , by 3 parallel straight lines, according to the equation  $-X_{\text{ion}} = c_1 Z + c'_2$ , where  $c_1$  has the same value as before and  $c'_2 = 6.70 \times 10^{-6}$  for the halogen ions,  $1.6 \times 10^{-6}$  for the alkali ions, and  $-5.10 \times 10^{-6}$  for the alk. earth ions.

W. W. STIFLER

**The diamagnetism of the ions of the noble-gas type.** HELMUTH KULENKAMPFF. *Ann. Physik* [5], 1, 192-4(1929).—According to Langevin's theory, the diamagnetic susceptibility is given by  $-X = e^2 L Z^2 r^{-2} / 6mc^2$  in which  $e$ ,  $m$  and  $c$  have their usual significance,  $L$  is the Loschmidt no.,  $Z$  is the no. of electrons, and  $r^{-2}$  is the av. of the squares of the distances of the electrons from the nucleus. The empirical equation found by Ikenmeyer (cf. preceding abstract) is of this form except for the const. term  $c'_2$ . If this term be neglected for the moment, the value of  $r^{-2}$ , calcd. by equating I.'s value for  $c_1$  to the right-hand side of the Langevin formula, is in excellent numerical agreement with that calcd. from Bohr's theory of the H atom. By considering that  $c'_2$  takes care of the change from the  $Z$  of I.'s empirical equation to the  $Z$  of Langevin's equations are derived which give  $r^{-2}$  for the halogen, alkali and alk. earth ions in terms of the const.  $a_1$  of the Bohr theory.

W. W. STIFLER

**The paramagnetic susceptibility of quinquevalent vanadium ion.** NICOLAS PERRAKIS. *Trans. Am. Electrochem. Soc.* 55 (preprint) 5 pp. (1929).—Two grades of  $V_2O_5$  were tested and also  $NH_4VO_3$  and  $NaVO_3$ . Both the ascension and attraction methods were employed. An av. value of  $44 \times 10^{-6}$  correct within 10% was found for the susceptibility of  $V^{+5}$ . This value is appreciably lower than the value Honda and Owen obtained for metallic V, but since this difference cannot be ascribed to errors in expt., it seems safe to conclude that an element may have several different values for the magnetic susceptibility. The need of further study is emphasized. C. G. F.

**The anomaly of the diamagnetism of gases found by A. Glaser.** HANS BUCHNER. *Ann. Physik* [5], 1, 40–8 (1929).—An error in Glaser's method (*C. A.* 20, 1350) of computing the temp. correction for his test specimen is discussed. It is shown that if there is any heat gradient in the app., the temp. of the specimen depends upon the pressure, and a change in temp. of only  $0.01^\circ$  accounts for the anomalies observed by Glaser. Preliminary results are given on the transfer of heat through  $CO_2$ ,  $H_2$ , and air at various pressures. W. W. STIFLER

**Coercive force and mechanical hardness.** A. KUSSMANN AND B. SCHARNOW. *Z. Physik* 54, 1–15 (1929).—The coercive force (magnetic hardness) was investigated as a function of mech. hardness and composition of alloys. It is shown that in solid solns. in which the lattice const., mech. hardness, elec. resistance, etc., change greatly as compared with the pure metals, the coercive force changes very little. In heterogeneous mixts. the coercive force is greater than in the pure elements, regardless of the change in hardness. The facts are explained by assuming internal strains in the material. GEO. GLOCKLER

**Recent progress in illinium.** L. L. QUILL AND B. S. HOPKINS. *Trans. Illinois Acad. Sci.* 21, 198–202 (1928); cf. *C. A.* 22, 2499.—A review article. L. L. QUILL

**The degree of association in liquid dielectrics.** M. WOLFFKE. Inst. of Technology, Warsaw. *Physik. Z.* 29, 713–6 (1928).—A statistical theory of simple assocn. in liquid dielectrics is given in which the degree of assocn. appears as a function of the concn. and temp. of the mixt. A satisfactory agreement of the theoretical results with exptl. measurements reported by previous investigators has been obtained in the case of  $EtOH$ ,  $PhCl$ , quinoline and  $PhNO_2$ . EMIL KLARMANN

**A superconductor made from two non-superconductors.** W. J. DE HAAS, EDM. V. AUBEL AND J. VOOGD. *Proc. Acad. Sci. Amsterdam* 32, 226–30 (1929).—The eutectic mixt. of Au and Bi was found to be superconductive. Two possible explanations are offered: (a) either Au or Bi is a superconductor under these conditions, although at  $1.25^\circ K.$ , when the mixt. shows the phenomenon, neither component is superconductive; (b) traces of impurity are responsible, although the temp. at which the resistance falls does not correspond to the transition temp. for any known metal. It is proposed to repeat the observations on purer materials. J. B. AUSTIN

**Measurements on the electrical resistance of some metals below the boiling point of oxygen.** W. TUIJN. *Proc. Acad. Sci. Amsterdam* 32, 115–23 (1929); cf. *Comm. Phys. Lab. Univ. Leiden* Nos. 160 (a and b), 167a, 181.—Measurements on the elec. resistance of Cd, Cu (crystals), Au, In, Pb, Pt, Th, Zn and Sn (single crystal) are given for temps. below  $90^\circ K.$  J. B. AUSTIN

**Nomenclature of electric discharge forms in air at atmospheric pressure.** MAX. TOEPLER. *Z. tech. Physik* 10, 113–8 (1929); cf. *C. A.* 23, 2617.—The discharge shape for large gaps and potentials was examd., a 1-cm. iron bar 50 cm. long with  $35^\circ$  point being used as point electrode on one side, a circular Zn disk of 200 cm. diam. on the other side. The ranges of existence of the various discharge types are illustrated in a graph and described for a gap of 60 cm., 500 kv. potential, d. c. with the point either negative or positive. Likewise the discharge between two-point electrodes is treated. For very large electrode distances the discharge is threefold; an intermediary zone can be considered as electrode-less discharge; it has various shapes from striped bands to lightning. Photographs are reproduced of arc discharges at large distances. B. J. C. VAN DER HOEVEN

**Calculation of the internal field due to polarization.** R. DE MALLEMANN. *Compt. rend.* 187, 536–8 (1928).—The use of tensor method allows a treatment of internal fields free from the logical imperfections of the Lorentz or cavity method. With this new method it is possible separately to expand the refractive index, and the optical rotation in the form of a series in the mol. diam. Diams. calcd. in this way agree closely with that calcd. in other ways. In a perfectly regular assemblage, e. g., a cubic crystal there is no polarization field. In liquids this field is due to the irregularities of the mol. motion. F. R. BICHOWSKY

New graphical appliance for the interpretation of rotation diagrams of crystals.

W. BÜSSEM AND K. HERRMANN. *Z. tech. Physik* 9, 148-54(1928); *Science Abstracts* 31A, 604. H. L. D.

Mesomorphic states. G. MAYR. *Nuovo cimento* 5 (*Rivista*), xxv-lv(1928); *Science Abstracts* 31A, 657.—The phenomena of liquid crystals and of anisotropic properties exhibited by liquids under the influence of velocity gradient, electrostatic stress or a magnetic field are considered to be evidence of a distinct state between the solid and the liquid. A long survey with references is made of the exptl. data and papers on these subjects, and the structure of the systems exhibiting these peculiar properties is discussed. H. L. D.

Velocity of water molecules leaving a dehydrating crystal. A. S. PREDVODITELEV. *Z. Physik* 54, 159-60(1929).—Correction and restatement of assumptions related to previous work (C. A. 23, 11). GEORGE GLOCKLER

Flowing of metal crystals produced by torsion. R. KARNOP AND G. SACHS. *Z. Physik* 53, 605-18(1929).—Five % Cu-Al alloy was studied under torsion and the expts. were interpreted from a crystallographic point of view and compared with the stretching expts. of K. and S. (cf. C. A. 22, 4294). GEORGE GLOCKLER

Crystal structure of thin metal foils. S. DEMBINSKA. *Z. Physik* 54, 46-52(1929).—Foil of Pt, Cu, Ni a few  $\mu$  in thickness show crystal structure. The thickness of the foils observed varied from 7 to 18  $\mu$ . They were produced by cathodic sputtering and by thermal evapn. The support upon which the metals are being deposited has an effect upon the crystal arrangement assumed by the layer. GEORGE GLOCKLER

Arrangement of microcrystals in compressed magnesium and aluminum plates. S. TSUBOI. *Mem. Coll. Sci. Kyōtō* 11A, 375-82(1928).—A circular plate of Mg 2.4 mm. thick was compressed to a thickness of 0.4 mm., and the arrangement of the microcrystals investigated by x-ray analysis. Most of the crystals were arranged fibrously with the principal axis of the hexagonal crystal in the direction of compression, but the arrangement was not exact. Al sheets of 1.8 mm. thickness were similarly reduced to 0.13 mm. by compression, both circular and approx. elliptical specimens being used. The microcrystals tended to take up a fibrous structure with the (110) planes parallel to the surface of the plate, and their [112] axes parallel to the direction of flow of the metal. Consequently, with the elliptical specimens the arrangement was different at the extremities of the major and minor axes because of the different directions of flow. B. C. A.

Imperfections of crystals. F. ZWICKY. *Calif. Inst. Tech. Proc. Natl. Acad. Sci.* 15, 253-9(1929).—Z. shows theoretically that even the most perfect crystals contain microscopic cracks. Since the max. lateral contraction on extension of rock salt crystals is 5.4%, the ions in one lattice plane will try to arrange themselves in a lattice characterized by spacings 6% smaller than the spacing in the solid crystal, while the surface planes will exhibit the same tendency to a lesser extent. The equil. configuration of the crystal being one of min. energy, and having thus a varying space lattice decreasing from the interior to the surface, then, since the surface cannot contract as a whole, there will be patches of a definite av. size, between which cracks will open. The new surface formed will be at the expense of the energy gained by the contraction, and V-shaped cracks will appear, not only on the surface, but throughout the entire crystal. In this way elementary blocks of about 10,000 atoms will be formed (Cf. C. A. 20, 1385). The surface of the elementary blocks will increase with an increase in the lattice const., and decrease with increasing tendency to a lateral contraction of the lattice plane forming the surface. The depth of the largest cracks will be detd. by the ratio of the energy of contraction to the surface energy, but in general the cracks will be irregularly distributed over the surface of the crystal. LOUIS WALDBAUER

The lattice constants of calcium oxide and calcium hydroxide. E. RUMPF. *Ann. Physik* 87, 595-6(1928).—The mean value, calcd. from 12 Debye-Scherrer plates, for the CaO lattice const. is 4.799  $\pm$  0.002 A. U. For Ca(OH)<sub>2</sub>, which is hexagonal, the values from three plates are:  $a$  = 3.582  $\pm$  0.001,  $c$  = 4.904  $\pm$  0.008 A. U. R. L. H.

Determination of the lattice constants of the mixed-crystal system KCl-KBr. FRIDA OBERLIES. *Ann. Physik* 87, 238-58(1928).—Mixed crystals of KCl and KBr were made by fusion, followed by slow cooling. These were examd. by the Bragg method, using a Cu anticathode. Due to vaporization from the W filament, W lines were also obtained. For KCl,  $d$  = 3.1362 A. U., for KBr,  $d$  = 3.2952 A. U. Vegard's additivity law holds within the exptl. error. No new interference lines, as would be expected from a regular arrangement of the components, were found. R. L. H.

Crystallography of aliphatic dicarboxylic acids. WILLIAM AUGUSTUS CASPARI. Davy-Faraday Lab. Royal Institution. *J. Chem. Soc.* 1928, 3235-41(1928).—Single crystals of adipic (C<sub>6</sub>), pimelic (C<sub>7</sub>), suberic (C<sub>8</sub>), azelaic (C<sub>9</sub>), sebacic (C<sub>10</sub>), brassylic

( $C_{13}$ ), and hexadecanedicarboxylic ( $C_{16}$ ) acids were examd. by the x-ray rotating or oscillating crystal method. The acids, with their  $a$ ,  $b$ ,  $c$  axial lengths in A. U., their  $\beta$ -angles, and the no. of mols. per unit cell, resp., are: adipic, 10.27, 5.16, 10.02,  $137^\circ 5'$ , 2; pimelic, 9.93, 4.82, 22.12,  $130^\circ 40'$ , 4; suberic, 10.12, 5.06, 12.58,  $135^\circ 0'$ , 2; azelaic, 9.72, 4.83, 27.14,  $129^\circ 30'$ , 4; sebacic, 10.05, 4.96, 15.02,  $133^\circ 50'$ , 2; brassylic, 9.63, 4.82, 37.95,  $128^\circ 20'$ , 4; hexadecanedicarboxylic, 9.76, 4.92, 25.10,  $131^\circ 10'$ , 2. The unit cells have nearly const.  $a$  and  $b$  axes; as regards the  $c$  axes, the acids fall into two groups, one having the mols. of even no. of C atoms, the other the odd. The  $c$  axes of the even-numbered mols. are proportional to the no. of C atoms; for the odd-numbered mols. they are proportional to twice the no. of C atoms. In the latter group, two mols. lie end to end in the cell along the  $c$  axis. The  $\beta$ -angles are always much smaller for the odd-no. acids than for the evens. The space lattice is  $\Gamma_m$ , the space group  $C_{2h}^6$ . If the mols. are asymmetrical, four mols. differently oriented must appear in the cell; if symmetrical two only appear. The first case corresponds to odd-no. acids, the second to even. If the mol. chain is zigzag, odd-no. mols. do not have center of symmetry, even-no. mols. do. The cross section of the cells perpendicular to  $c$  is fairly const. at about  $36 \text{ A. U.}^2$ , a value in good agreement with that found for all other long-chain aliphatic compds. The data indicate a mean difference of 1.53 A. U. between C atoms. The gap between C chains along the  $c$  axis which is occupied by the O and H atoms of two carboxyl groups is about 2.09 A. U. and somewhat larger than that found for the hydrocarbon  $C_{20}H_{42}$ , as might be expected.

R. L. HERSHEY

The crystal structure of strontium and barium. FRITZ EBERT AND HELLMUTH HARTMANN. *Z. anorg. allgem. Chem.* 179, 418-20(1929).—Cryst. structure was detd. at room temp. by the powdered-crystal method of x-ray analysis. Sr has a face-centered cubic structure with  $a = 6.05 \text{ A. U.}$  Ba has a body-centered cubic structure with  $a = 5.01 \text{ A. U.}$

R. J. HAVIGHURST

Stretching of cadmium crystals. W. BOAS AND E. SCHMID. *Z. Physik* 54, 16-45 (1929).

GEORGE GLOCKLER

Influence of admixtures to sodium nitrate solutions on the structure of the crystals obtained. P. P. ORLOV. *Bull. Acad. Sci. Union Rep. Sov. Soc. Class Sci. Phys.-Math.* No. 6-7, 529-48(1928).—The fundamental idea expressed by O. in 1896 on the basis of observed changes of the cryst. structure of NaCl, that the structure of crystals is influenced by adding admixts. which are apt to react both with the solvent and with the solute, is now confirmed by the changes of the cryst. structure of  $\text{NaNO}_3$ . In the latter case the admixts. affecting the structure are: formamide, hydroxyisobutyric acid, lactic acid, etc. A microscopic examn. of  $\text{NaNO}_3$  crystals obtained from hot solns. contg. any of the above reagents reveals sharp-edged rhombohedrons and double crystals; on cooling, they become covered by scales and apparently tend to revert to the usual rhombohedral structure. Very concd. solns. of  $\text{Cr}(\text{NO}_3)_3$ , particularly after standing for a long time, have the effect of dulling (blunting) the edges of  $\text{NaNO}_3$  crystals. A lengthy discussion of the possible nature of the interaction of these admixts. is given.

BERNARD NELSON

Crystal structure of trimethylethylammonium chlorostannate. R. W. D. WYCKOFF AND R. B. COREY. Rockefeller Inst. N. Y. *Am. J. Sci.* 17, [5], 239-44(1929).— $[\text{N}(\text{CH}_3)_3\text{C}_2\text{H}_5]_2\text{SnCl}_6$  has been examd. by the Laue and spectrographic methods. The crystals are cubic, contain 4 mols. per unit cells; the length of the unit cell is 13.17 A. U. The Sn and Cl atoms are at  $4b$  and  $24a$  with  $a$  for Cl =  $0.185 \pm 0.01$ . The chlorostannate groups are of the same size, shape and distribution as in  $(\text{NH}_4)_2\text{SnCl}_6$ . The suggested arrangement of the C and N atoms in the  $[\text{N}(\text{CH}_3)_3\text{C}_2\text{H}_5]$  groups gives the same approx. distances as in analogous compds. The structure is like that of  $\text{CaF}_2$ ; the space group is  $\text{Ti-6}$ .

R. L. HERSHEY

Orientation of single crystals of zinc. K. TANAKA. *Mem. Coll. Sci. Kyōto* 11A, 361 5(1928).—Com. Zn plates 1.5 mm. thick were rolled to 20-70% reduction in thickness, and large crystals grown by annealing at  $400^\circ$  for 1 day. X-ray examn. showed that in most of these crystals the base of the hexagonal crystal was parallel to the plane of the plate. A similar arrangement was found when the plates were extended instead of being rolled before annealing. On drawing com. zinc wires 1.5 mm. diameter through a 0.5-mm. die and then annealing, most of the resulting crystals had their  $[11\bar{2}0]$  axes parallel to the axis of the wire. A rather random distribution was obtained after annealing a wire extended for a small percentage only. When a circular zinc plate is melted, and then cooled gradually from the circumference, large crystals grow towards the center, and most of them grow parallel to the plane of the base of the hexagonal crystal.

B. C. A.

**Lattice dimensions of spinel ( $MgAl_2O_4$ ).** E. POSNJAK. *Am. J. Sci.* 16, 528-30 (1928).—The spinel was prepd. by heating a mixt. of  $Al_2O_3$  and  $MgCO_3$  in the correct proportion to about  $1700^\circ$ . The resulting sintered product was fine-grained and isotropic and had a refractive index of  $1.717 \pm 0.002$ . The radiation used was  $K\alpha$  of Mo and the spacings were standardized with NaCl. A table gives complete powder diffraction data for the spinel. The mean length of the edge of the unit cube is  $8.03 \pm 0.01$ . In the spinel structure 8 mols. are associated with the unit cell. The calcd. d. of the spinel was found to be 3.628, which agrees within 2% with E. Dufau's [*Bull. Soc. Chem.* 25, 669(1901)] value of 3.57.

A. J. MONACK

**The change that a gaseous molecule may undergo between two consecutive collisions.** R. D. KLEEMAN. *Phil. Mag.* [7], 7, 53-63(1929).—K. has shown previously (*C. A.* 22, 3086) that  $pv = \xi MRT$ , where  $\xi$  is a function of  $T$ ,  $v$  and  $M$ . He now shows that  $\xi$  is an inverse function of the vol. From this it follows that the velocity of a mol. in a gas changes between two consecutive collisions. He further discusses the effect of heat radiation on the mol. velocity of translation and suggests exptl. methods of investigating the nature of the function  $\xi$ . K. applies the above ideas to an electron gas and to Carnot's cycle.

L. H. REYERSON

**The pressure of gaseous mixtures. II. Helium and hydrogen and their intermolecular forces.** C. W. GIBBY, C. C. TANNER AND IRVINE MASSON. Univ. of Durham, Eng. *Proc. Roy. Soc. (London)* A122, 283-304(1929); cf. *C. A.* 17, 2804.—The compressibility of He and H and 10 mixts. of the 2 were measured up to 125 atm at  $25^\circ$ . The pure gases and an equimol. mixt. were also studied at  $25^\circ$ ,  $50^\circ$ ,  $75^\circ$ ,  $100^\circ$ ,  $125^\circ$ ,  $150^\circ$  and  $175^\circ$ . The method consisted in a series of comparisons of 2 vol. ratios; one, for the gas under investigation, the other for the manometric gas H, both being mounted in the same app. and subject to the same pressures. The pressure measurements were indirect, in that they were calcd. from the observed H vol. by using the compressibility data of Holborn and Otto for this gas (cf. *C. A.* 19, 926). The deviations from Dalton's law of partial pressures were positive and at a max. in an equimol. mixt., for which, at high compression they attain 4% of the ideally additive pressure. Within a certain range of compn. the mixt. is still more incompressible than H. The data are expressible by equations of the form  $pv = a + bp$  within the exptl. limits of  $\pm 5$  parts in 10,000. The values of  $a$  and  $b$  are tabulated. The observations support the assumption that a spherically symmetrical field of force surrounds a He and a H mol. The influence of temp. upon the values of  $b$ , for the pure gases and mixts., is examined in the light of Lennard-Jones' analysis of intermol. forces (cf. *C. A.* 21, 3290).

R. L. DODGE

**Budde effect in bromine and chlorine.** GEORGE B. KISTIAKOWSKY. *J. Am. Chem. Soc.* 51, 1395(1929).—Using simultaneously a sensitive manometer and a Pt-thermometer, the author shows that neither the warming nor the expansion of halogens on illumination is affected by extreme drying and purification.

G. B. KISTIAKOWSKY

**The electrical conductivity of potassium chloride vapor.** T. PEĆZALSKI AND J. CICHOCKI. *Compt. rend.* 187, 534-6(1928).—The satn. current of KCl vapor at  $550^\circ$  between Cu electrodes at 90 volts is about  $10^{-4}$  amp. This current decreases with the time in consequence of polarization. Chlorine is liberated at the anode. KCl vapor is about 0.002% dissociated into ions at this temp.

F. R. BICHOWSKY

**Determination of gas temperatures by measurement of pressure difference.** HANS SCHMICK. *Z. tech. Physik* 10, 146-7(1929).—The principle of measuring the temp. of a gas by means of the flow of a certain amt. through 2 orifices in series is discussed briefly. If the gas has an unknown abs. temp.  $T_1$  at one orifice and a known temp.  $T_2$  at the next one the measured pressure differentials  $\Delta p_1$  and  $\Delta p_2$  will be proportional to these temps. The exptl. errors were found to be considerable (cf. also Göbel, *Ber. d. Stahlwerksausschuss d. V. d. Eisenhüttenl.* No. 105(1926)), as much as 15% of  $\Delta p$  in some expts. on a gas furnace and on a Bunsen flame.

B. J. C. VAN DER HOEVEN

**Thermal conductivity of gas mixtures.** T. L. IBBS AND A. A. HIRST. *Proc. Roy. Soc. (London)* A123, 134-42(1929).—A method is described of estg. thermal cond. of gas mixts. by the use of Shakespear's katharometer. From known cond. of A-He mixts. and calibration curve of the instrument with these gases, cond. of  $O_2$ , CO,  $CO_2$ ,  $H_2$ ,  $N_2$  and mixts. of these gases were calcd.

G. B. TAYLOR

**The effect of intensive drying on certain physical properties of benzene.** HENRY V. A. BRISCOE, JOHN B. PERL AND PERCY L. ROBINSON. Univ. Durham. *J. Chem. Soc.* 1929, 368-77.—Expts. were made to det. the effect of intensive drying on the density and surface tension of  $C_6H_6$ . At present, the  $C_6H_6$  has stood for 16 months in contact with  $P_2O_5$  in several forms of sealed app. The changes in d., measured by calibrated floats, do not exceed 5-7 parts per 100,000, and confirm Baker's conclusion

that intensive drying does not change the d. of  $C_6H_6$ . This has been found to apply not only to the sample as a whole, but also to fractions obtained by distn. When brought into contact with  $P_2O_5$ ,  $C_6H_6$  changes in d. by 1 part in 8000 during the first few days only, as a result of the soln. of the oxide. The max. observed change in capillary rise on 16 months drying was 0.4 mm., as compared to the 6 mm. expected from previous results of Baker. The surface tension of  $C_6H_6$  in contact with  $P_2O_5$  was not appreciably different from  $C_6H_6$  distd. from  $P_2O_5$ . No evidence of the sepn. of pseudo components as a result of intensive drying could be found. M. W. S.

Relations of coefficient of compressibility of liquids and solids. N. BĂRBULESCU. *Bul. stiinte fizice soc. română stiinte* 29, 29-34 (1926-7). (In French).—The value  $0.5 \times 10^6$  obtained by Richards for compressibility of diamond is not correct, although the sp. heat theory proposed by Born and Kármán leads to almost the same value. To obtain an abs. temp. of fusion exceeding  $3400^\circ$  there must be assumed for compressibility of diamond a max. value of  $0.1 \times 10^{-6}$ . E. M. SYMMES

Viscosity of binary systems of liquids. N. N. EFREMOV. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 118-59 (1928).—Chloral and bromal form alcoholates of various degrees of stability. In the liquid phase they are usually partially dissoed. into their components. Systems chloral-allyl alc. and nitrobenzene-isobutyl alc. were investigated in detail.  $CCl_3CHO \cdot C_4H_9OH$  is stable even at elevated temps. Density isotherms of the system chloral-allyl alc. are smooth curves and the change in the temp. coeff. of internal friction is analogous to the change in viscosity. Density isotherms of the system nitrobenzene-isobutyl alc. approach straight lines and the change in the temp. coeff. of internal friction is also similar to the change in viscosity. Nitrobenzene has a higher sp. gr. but smaller viscosity than isobutyl alc. up to  $77^\circ$ , when both have the same viscosity because of the high temp. coeff. of isobutyl alc. The temp. coeff. diminishes rapidly with increase in temp. and at  $65$ - $105^\circ$  the curves are almost straight lines. V. KALICHEVSKY

Electric conductivity of binary liquid systems of allyl mustard oil and amines. N. VOSKRESENSKA. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 160-82 (1928).—Systems of allyl mustard oil, b.  $150.5$ - $151.0^\circ$ , with dimethylaniline, b.  $193$ - $193.5^\circ$ , diethylaniline, b.  $215$ - $215.3^\circ$ , pyridine, b.  $116$ - $117^\circ$ , methylaniline, b.  $193.5$ - $194.0^\circ$ , and ethylaniline, b.  $203.5$ - $204^\circ$ , were investigated. Sp. cond. varied from  $17.81 \times 10^{-6}$  to  $1340 \times 10^{-6}$ . Considerable time was required for cond. to attain a const. value. None of the diagrams (compn. vs. cond.) approached a straight line. Systems of allyl mustard oil with tertiary amines, which do not react, show a max. cond. that is 6-70 times greater than the cond. of individual components. Systems with secondary amines, which react, show two max. with a min. at the points closely approaching equimol. concn. V. KALICHEVSKY

Temperature—conductance curves of solid salts. II. Halides of potassium and thallium. T. E. PHIPPS AND E. G. PARTRIDGE. *J. Am. Chem. Soc.* 51, 1331-45 (1929).—Tables are given to show the relation between  $\log k$  (logarithm of sp. conductance) and  $1/T$  (reciprocal of abs. temp.) for  $TlCl$ ,  $TlBr$  and  $TlI$ . These data are also shown graphically. The heat of liberation (C. A. 20, 2102) for  $TlCl$  was found to be  $11.48 \times 10^{-13}$  ergs per ion; for  $TlBr$  the value was  $11.64 \times 10^{-13}$ . The  $\log k$ - $1/T$  curve for  $TlI$  shows 2 slopes. The heat of liberation for the upper slope was  $10.0 \times 10^{-13}$ , while that for the lower slope was  $6.6 \times 10^{-13}$  ergs per ion. Values of  $\log k$  and  $1/T$  for  $KCl$  crystals and  $KCl$  pellets (formed by compressing  $KCl$  in a die by means of high pressure) are given. The heats of liberation for  $KCl$  crystals are  $32.1 \times 10^{-13}$  for the upper slope and  $15.7 \times 10^{-13}$  for the lower slope; values for  $KCl$  pellets are  $30.3 \times 10^{-13}$  for the upper slope and  $14.7 \times 10^{-13}$  for the lower slope.  $\log k$  and  $1/T$  data are given for  $KBr$  crystals and pellets and  $KI$  pellets. The heats of liberation are as follows:  $KBr$  crystals, upper slope  $31.3$ , lower slope  $15.4 \times 10^{-13}$ ;  $KBr$  pellets, upper slope  $29.2$ , lower slope  $14.4 \times 10^{-13}$ ;  $KI$  pellets, upper slope  $25.7$ , lower slope  $13.5 \times 10^{-13}$  ergs per ion. It was found in most cases that the heat of liberation calcd. from the upper slope is approx. double that from the lower slope. It is concluded that in the polar lattices only the positive ion conducts at lower temps. but that both ions conduct at higher temps. A. J. MONACK

Surface conductance. DAVID R. BRIGGS. *Colloid Symposium Monograph* 6, 41-52 (1928).—In aq. solns. of low sp. cond. present in the interstices of a diaphragm material, e. g., pure paper pulp, the elec. conductance through the interface phase is much greater than that through an equal vol. of liquid in bulk. This fact has been largely neglected in calcs. of the  $\zeta$  potential at interfaces when electrokinetic technic was used. There is described and illustrated a method and app. for detn. of surface conductance of diaphragms, which is important in electrokinetic detns. only when

solns. have low sp. conductivities, or when the micellar material has a high sp. surface area. Salt solns. show definite valence and lyotropic effects on surface conductance.

JEROME ALEXANDER

Electrical relations at surfaces, the spreading of liquids, the thickness of surface films, and the drop-weight and ring methods for the determination of surface tension. WILLIAM D. HARKINS. *Colloid Symposium Monograph* 6, 17-40(1928).—Hexane, emulsified in 0.1 M Na oleate gives droplets mainly 1 to 1.5 $\mu$  (limits about 0.2-10 $\mu$ ). A 1- $\mu$  droplet is surrounded by approx. 10 to 15 million negative oleate ions and oleic acid mols., and thus acts like a multivalent ion of very high charge, surrounded by a diffuse (Gouy) layer of positive ions. If a current passes, the Na ions moving toward the negative electrode tend to follow the contour of the droplets and to drag some negative ions and the solvent with them at a less velocity. While Stokes' law may be expected to hold if the droplets rise under the influence of gravity, motion in a current is affected by this elec. flow of solvent. Stokes' law indicates that the 1- $\mu$  particles have a negative charge of 2430; i. e., only a few of the film-mols. are ionized. By applying the formula for the potential of a charged sphere, the droplet shows a  $\phi$  potential of 84 milliv., which corresponds to the  $\psi$  potential calcd. from the Debye-Hückel theory. Contrary to common assumption, larger drops move faster than smaller ones (Mooney), though electrolytes diminish the difference. II. (With BERNARD GINSBERG.) *Ibid.*—Formulas are developed thermodynamically, for the spreading coeff. If enough benzene is dropped on pure water to make a layer about 1 mm., it spreads to make a uniform surface layer, as is expected from the initial spreading coeff. of 8.9. The 'holes' which appear in this layer as the benzene evaps., are found, by surface-tension measurements, to be covered with a monomol., or thicker, invisible film of benzene. The film surrounding the holes accords with the value of the final spreading coeff. of -1.49 ergs per sq. cm., and indicates a considerable angle of contact. Many exptl. data are given to show that Antonow's rule, generally considered valid in books on surface tension, etc., is not valid. A new drop-wt. app., devised by H. N. Harkins, P. L. K. Gross and W. D. Harkins is described and illustrated. III. (With D. M. GANS.) Monomol. and polymol. films are discussed. Many writers use equations derived from the basic equation of Gibbs by inaccurate assumptions. IV. (With H. F. JORDAN.) Improvements in the ring method for detn. of surface tension are suggested: (1) The liquid under test is placed in a shallow vessel within a spherical flask, and a clean surface is made by overflowing; (2) the pull is detd. by a chainomatic balance sensitive to 0.05 mg.; (3) to avoid surface waves, the balance is raised by a train of gears; (4) the Pt-Ir ring has a double stirrup; (5) the plane of the ring is made exactly parallel to the liquid surface; (6) the large size of the contg. vessel obviates the need of a correction for surface curvature.

JEROME ALEXANDER

Critical-temperature measurements on carbon dioxide in small capillaries. HARVEY T. KENNEDY. *J. Am. Chem. Soc.* 51, 1360-6(1929); cf. C. A. 22, 2966.—The app. by which the CO<sub>2</sub> was purified is illustrated and described. Detns. of crit. temps. were made on samples contd. in 2 small capillaries whose internal diams. midway between the 2 ends were 0.004 and 0.060 mm., resp. Several detns. were also made with a 2-mm. tube. The crit. temp. was found to be independent of the size of the tube; 30.96° was taken as the most probable value. Large differences in crit. point were found for different methods of illumination.

A. J. MONACK

The life history of adsorbed atoms and ions. JOSEPH A. BECKER. *Trans. Am. Electrochem. Soc.* 55 (preprint) 21 pp.(1929).—Adsorbed particles may exist on the surface either as positive adions (adsorbed ions) negative adions or adatoms. Whether a given substance will be adsorbed as an atom, a positive ion or a negative ion, will depend on the fields of force that exist near the metal surface, and near the particle at their distance of nearest approach. The ratio of adions to adatoms can be determined from thermionic expts. The adsorbed ions produce elec. fields, which extend to 10 or more atom diameters, which close to the surface may attain enormous values, and which appreciably alter the electron work function and the evapn. energy for atoms and ions. The ratio of ions to atoms that evaporate from one and the same surface is detd. by the electron work function of the surface and the ionization potential of the adsorbed particles. Within a certain range of temp., the adsorbed particles migrate over the surface like a two-dimensional gas. Adatoms and adions have chem. properties vastly different from those of ordinary atoms. The length of time that an atom remains on the surface before evapn. is detd.

C. G. F.

The activity and adsorption of *p*-toluidine in the surface of its aqueous solution. J. W. MCBAIN, W. F. K. WYNNE-JONES and F. H. POLLARD. *Colloid Symposium Monograph* 6, 57-62(1928).—The partial pressure and activity of aq. *p*-toluidine are

proportional to the concn. This supports the 2-fold conclusion of McBain and Davies: 1st direct exptl. observations show that in all these solns. of sol. substances, even when far from satn., the surface is covered with a monomolecular film of solute, and there is also a large excess in the neighborhood of the surface, probably extending in the form of oriented mols. well into the soln.; 2nd the thermodynamic treatment of Gibbs, generally followed, is insufficient, because it omits consideration of adsorption resulting from the admitted electrification of all such surfaces, as exhibited for instance in expts. on electrokinetics.

**Adsorption of sodium oleate at the air-water interface.** M. E. LAING, J. W. MCBAIN AND E. W. HARRISON. *Colloid Symposium Monograph* 6, 63-72(1928).—Contrary to the predictions of the Gibbs theorem, both in its popular and in its exact form, Na oleate is positively adsorbed in the air-water interface. The amt. adsorbed is nearly twice as great as can be packed into a monomolecular film. This supports the views of McBain and Davies (cf. preceding abs.), based on findings with *p*-toluidine, camphor and amyl alcohol. The adsorbed soap is in hydrolytic equil. with the soln., but its hydrolysis is completely suppressed by a small excess of alkali. JEROME ALEXANDER

**The adsorption of methylene blue by lead sulfate.** WILDER D. BANCROFT AND C. E. BARNETT. *Colloid Symposium Monograph* 6, 73-6(1928).—For any concn. of dye, the amt. of adsorption by a powd. solid is a function of the apparent  $p_H$  of the soln. The max. adsorption of a dye by a crystal is no safe criterion of the total surface of the crystal. Therefore Paneth's method in its present form, is not reliable. Contrary to Marc's statement,  $PbSO_4$  crystals adsorb methylene blue, but the amt. lies within his large exptl. error. JEROME ALEXANDER

**The effect of adsorbed water on the electrical conductivity of powders.** FRANK B. KENRICK AND F. J. GIFFEN. *Colloid Symposium Monograph* 6, 53-6(1928).—The method consists in measuring, by means of an electroscope, the rate of discharge of a condenser through the powder under various conditions of moisture, fixed by passing air of known water content through the powders. Some powders, e. g., glass, conducted well even with small concns. of water vapor; others, like salicylic acid, remained practically non-conducting until the satn. point was reached, when all powders conducted well. In general, substances which initiate bubbles when in contact with aq. solns. of O (satd. at 30-40 atm. pressure) are less conducting in damp air. The initial cond. of glass dropped on standing after moistening, and rose after dry air produced an initial drop in the moistened glass. This suggests an equil. between a surface of adsorbed water and water dissolved in the glass. JEROME ALEXANDER

**Some adsorption phenomena on silver iodide.** II. A. OBRUCHEVA. *Biochem. Z.* 207, 25-7(1929).—The adsorption of caprylic acid, octyl alc., etc., by AgI is studied quant. S. MORGULIS

**Investigation on adsorption of gases and vapors on different kinds of silica gel.** F. BOSSHARD AND E. JAAG. *Helv. Chim. Acta* 12, 105-13(1929).—The adsorptive capacity of  $SiO_2$  gels for  $SO_2$  and  $Br_2$  as affected by the method of prepn. of the gel was studied. All gels prepd. followed the Freundlich equation. A. WHITE

**Lyosorption in organic liquids.** W. HALLER. *Kolloid-Z.* 46, 366-7(1928).—Different powdered substances, talc,  $Al_2O_3$ ,  $SiO_2$ ,  $MgO$ ,  $CaCO_3$ ,  $Fe_2O_3$ , graphite and Norit, were shaken with org. liquids and allowed to settle. The vol. occupied by the powders differed with the liquids, the liquids falling in the same series for each powder. In the order of largest vol. they were:  $CCl_4$ , benzine, benzene,  $CHCl_3$ ,  $Et_2O$ ,  $AcOH$ ,  $EtOH$  and  $Me_2CO$ . The resistance offered to a flow of these liquids through a plug of the powdered materials stands in the same order. The property of the liquid involved is its ability to be adsorbed on the solid surface and the process is called *lyosorption*. The sp. polarization,  $P_e$  of the liquid parallels its lyosorption.  $P_e = [(\epsilon - 1)/(\epsilon + 2)] \cdot (1/d)$ , where  $\epsilon$  = the dielec. const. and  $d$  the density of the liquid. J. G. McNALLY

**Remark on the paper of H. Staudinger: The constitution of high molecular substances.** KURT H. MEYER. *Naturwissenschaften* 17, 255(1929); cf. *C. A.* 23, 2334.—Objections are raised to the mol.-wt. detns. of S. It is pointed out that solvation has not been taken into account. The differences in opinion of S. and of Mark and the author are particularly stressed. B. J. C. VAN DER HORVEN

**The structure of the threads obtained by drying solutions containing ferric chloride.** PAUL BARY. *Compt. rend.* 187, 538-40(1928).—Two classes of filaments are formed by allowing basic  $FeCl_3$  solns. to evap., concentric and needle-like. These filaments consist of (1) a less hydrophilic colloid mostly of  $Fe_2O_3$  and (2) a more hydrophilic gel contg. more  $FeCl_3$ . F. R. BICHOWSKY

**Influence of organic substances on the thixotropy of ferric oxide sol.** H. FREUNDLICH AND K. SÖLLNER. *Kolloid-Z.* 43, 348-55(1928).—The liquefying action of amino

acids on a thixotropic sol cannot be related to the diminution in H-ion concn. (which rather promotes setting), for addn. to amino acids (glycine, alanine) both to concd. thixotropic  $\text{Fe}_2\text{O}_3$  sols and to dil., non-thixotropic sols lowers the H-ion concn. The action is considered to be due to the tendency of amino acids to form complex ferric salts, which are notably hydrophilic. The complexes bound to the colloid particle increase in water content and favor sol formation. Other substances (e. g., sugar) which form complexes with ferric salts also influence the thixotropy in the same sense as do amino acids. Contrary to results formerly obtained with small quantities of glycine, larger amts. have a peptizing effect on  $\text{Fe}_2\text{O}_3$  sols and thus raise the coagulation value. The relation between time of setting,  $\theta$ , and electrolyte concn.,  $c$ , can be expressed for  $\text{Fe}_2\text{O}_3$  sols by the formula  $\theta = e^{-c/k}$ , where  $k$  is a constant. B. C. A.

The coagulation of highly solvated sols by organic liquids and salts. III. BR. JIRGENSONS. *Kolloid-Z.* 47, 236-43(1929); cf. C. A. 23, 1333.—The coagulation of albumin, hemoglobin and casein by  $\text{EtOH}$ ,  $\text{C}_2\text{H}_5\text{OH}$  and  $\text{Me}_2\text{CO}$  from sols. contg. high concns. of inorg. salts was studied. At concns. up to 30-40% by vol., the org. liquid sensitized the soln. Between 30 and 60% a region of stabilization appeared and the sol was again sensitized at concns. above 60%. The dipole action of the org. liquid on the shell of adsorbed ions and water around the micelles tends to disrupt the shell and cause coagulation. Stabilization is caused by the dipole action of the inorg. salt ions adsorbed on the micelles. This dipole action reaches a max. and decreases as the concn. of org. liquid increases. J. G. McNALLY

The effect of temperature on the coagulation of copper colloidal solution. E. F. BURTON AND MRS. BEATRICE RIED DEACON. *Colloid Symposium Monograph* 6, 77-82 (1928).—If samples of Cu colloid were raised to different high temps. for half an hour, there existed one temp. below which the samples were not coagulated and above which they were coagulated as a result of this heating. Copper tubes were used, because impurities dissolved from glass acted as coagulants. Heat speeds the coagulation, though from indications, certain Cu colloids might be expected to remain stable indefinitely at room temp. JEROME ALEXANDER

Coagulation kinetics of colloids of the second order. K. JABLONZYNSKI AND MISS H. JASZCZOLT. *Roczniki Chem.* 9, 111-4(1929).—The velocity of coagulation of colloids, studied spectrophotometrically, is detd. by the equation:  $\log [(\log \text{tg } \alpha_\infty - \log \text{tg } \alpha_0)/(\log \text{tg } \alpha_\infty - \log \text{tg } \alpha)] = K_1 t$  (cf. C. A. 22, 3080; 21, 684), provided the final angle measuring the opacity be approx.  $90^\circ$ ; if that angle is smaller than  $90^\circ$ , the coagulation velocity is expressed by the equation:  $\log \text{tg } \alpha - \log \text{tg } \alpha_0 = K_1 t$ . Both equations were tested for the colloids of the second order  $\text{AgCl}$  and  $\text{AgBr}$  in the presence as well as in the absence of gum arabic. JAROSLAV KUČERA

Jellies and gelatinous precipitates. P. P. VON VEIMARN. *Kolloid-Z.* 46, 356-8 (1928).—Jellies are classified as either membrane or network jellies. The methods of prep. each type, the form of the dispersed particles and the influence of mech. factors on the formation of jellies are discussed. J. G. McNALLY

The influence of the relative volumes of solid and liquid phase on swelling. PAUL P. KESSENBAUM. *Kolloid-Z.* 46, 367-8(1928).—Both the rate and extent of gelatin swelling in water depend on the amt. of gelatin in contact with a unit vol. of water. This relationship is influenced by the nature and amt. of other reagents present in the system and by the purity of the gelatin. The adsorption of these reagents by the gelatin accounts for the influence of the vol. of gelatin on its water adsorption. J. G. McNALLY

Preparation of negatively charged sols by means of tartaric acid. V. Physico-chemical properties of tungstate-tartaric acid colloids. A. V. DUMANSKII AND S. I. D'YACHKOVSKII. *Kolloid-Z.* 48, 49-57(1929).—See C. A. 23, 2341. E. C. M.

The cooling curves of gelatinizing systems. MARTIN H. FISCHER. *Kolloid-Z.* 46, 359-66(1928).—The time-temp. curves of rapidly cooled sols. of-Na soaps show kinks in the curve corresponding to an exothermic change at the point where the soln. becomes opaque. These cooling curves are similar to those of hydrated salts dissolved in their water of crystn. The exothermic change is thought to be caused by the swelling of the soap micelles, which process resembles the recombination of the inorg. salt mol. with its water of crystn. J. G. McNALLY

Soap gels. P. A. THIESSEN. *Kolloid-Z.* 46, 350-5(1929).—The formation of crystn. centers in Na oleate hydrosols was studied and found to follow the same laws as the crystn. of single-phase melts. The clean soap sols. were rapidly cooled at a temp. of about  $0^\circ$ , allowed to remain at this temp. for a time and then warmed to  $12-15^\circ$ . The no. of macroscopic particles that were visible after standing for a given period of time at this higher temp. was taken as an index of the crystn. nuclei formed.

The no. of such nuclei increased rapidly when the temp. of supercooling was decreased beyond a critical temp. ( $+1^\circ$  for a 12.9% sol.), and increased as a linear function of the time of supercooling and the concn. of the soln. Solns. held at a high temp. before supercooling gave fewer crystn. centers than similar solns. that had been kept at lower temps. Photomicrographs of the nuclei in the clear soln. show the same structure as the solid phase previously observed in the opaque gels produced by cooling.

J. G. McNALLY

**Fractionation of gelatin.** M. KUNITZ AND JOHN H. NORTROP. Rockefeller Inst. *J. Gen. Physiol.* 12, 379-90(1929).—A salt-free soln. of gelatin of  $p_H$  4.7 may be sepd. into 2 fractions at  $23^\circ$ , one sol. in water at any temp., the other insol. in water even when heated to  $80^\circ$ . The sol. fraction is proportionally much greater than the insol. fraction. The insol. fraction does not swell in water, but swells in and is finally dissolved by acid and alkali. Blocks of concd. gel composed of various mixts. of the sol. and insol. fractions, made by dissolving the fractions in dil. NaOH, swell differently when placed in large vols. of dil. buffer soln. of  $p_H$  4.7 at  $5^\circ$ . The gel consisting of the insol. fraction shows only a trace of swelling, whereas swelling increases rapidly with the increase in the proportion of the sol. fraction. The insol. fraction made up to a 5% gel in dil. NaOH soln. loses about 70% of its wt. if placed in buffer soln. of  $p_H$  4.7 at  $5^\circ$ , whereas a similar gel made from ordinary gelatin loses only about 20% of its wt. under the same conditions. Isoelec. gelatin cannot be resynthesized from the two fractions. An insol. substance similar to the insol. fraction obtained by repptn. of gelatin is produced on partial hydrolysis of gelatin in dil. HCl soln. at  $90^\circ$ .

C. H. RICHARDSON

**The double refraction of plastic materials.** W. STAUF. *Kolloid-Z.* 46, 345-50 (1928).—The double refraction produced by strain is proposed as a test for such plastic materials as celluloid, casein, glyptol resins, etc. In the case of celluloid made from an 11% N nitrocellulose, the only material on which exptl. data are given, the accidental double refraction is positive at 40% elongation up to 30% camphor, 40% giving negative double refraction. The accidental double refraction increases as the temp. of stretching decreases and is decreased by the addn. of most plasticizers.

J. G. McNALLY

**Influence of solvent on the optical rotation dispersion.** A. L. TH. MOESVELD. *Proc. Acad. Sci. Amsterdam* 32, 344-55(1929).—See C. A. 23, 1553. E. C. M.

**Solubility of antimony in water.** JULIUS GRANT. *Analyst* 54, 227-8(1929).—Finely divided Sb is distinctly sol. in water and air. This was noticed in the study of some Sb deposits. Therefore, when Sb deposits are washed with water, some of the metal is likely to be dissolved. In the absence of air, the soly. is very much less in the case of both electrolytic deposits and powdered Sb.

W. T. H.

**The Debye formula.** N. BARBULESCU. *Bul. stiint. fizice soc. rom. stiint. 29*, 9-14(1926-7).—The Debye formula for sp. heat of solid substances is deduced by integration of the Planck equation, by assuming that the total radiation of an oscillating system is proportional to the internal energy of the system.

E. M. SYMMES

**Distribution of trichloroacetic acid between water and organic solvents.** I. M. ANDREASOV. *Ukrainskii Khim. Zhur.* 3, Sci. part, 463-6(1928).—Timofeev (*Nauka na Ukraine*, No. 4; cf. C. A. 11, 788; 20, 2820), showed that the mol. wt. of  $\text{CCl}_3\text{CO}_2\text{H}$  (I) is different in active solvents (capable of lowering the range of esterification) and in inactive solvents. To obtain new data for mol. conditions of I in the same solvents, A studied the distribution of I between  $\text{H}_2\text{O}$  and a corresponding solvent. According to the Bertholet-Nernst law in case of equal mol. wt. of distributed substance in both of the immiscible solvents the ratio of concns. must be const.:  $C_1/C_2 = K$ , and in case of unequal mol. wt.:  $C_1^n/C_2 = K$ . As in aq. soln. the mols. of I are hydrated, no associated mols. are present. The same applies to the active solvents where mols. of the acid are dissoed. Therefore the distribution of I between  $\text{H}_2\text{O}$  and the active solvent must be according to the 1st equation. In inactive solvents the mols. of I are more or less assocd., and the distribution of the acid between them and  $\text{H}_2\text{O}$  must be according to the 2nd equation, where  $c_1$  is the concn. of the acid in the aq. layer,  $C_2$  in inactive solvent, and  $n$  the degree of assocn. of I in inactive solvent. From the tabulated results it can be seen that the wider the range of reaction in an inactive solvent the greater is the coeff. of distribution. The various solvents can thus be classified according to the range (Timofeev, C. A. 9, 2896):  $\text{CS}_2 > \text{CHCl}_3 > \text{C}_6\text{H}_6 > \text{CCl}_4 > \text{C}_6\text{H}_5\text{NO}_2$ , and according to the coeff. of distribution thus:  $\text{CS}_2 > \text{CHCl}_3 > \text{CCl}_4 > \text{C}_6\text{H}_6 > \text{C}_6\text{H}_5\text{NO}_2$ . From the study of the coeff. of distribution it follows that in  $\text{C}_6\text{H}_6$ ,  $\text{C}_6\text{H}_5\text{NO}_2$ ,  $\text{CHCl}_3$  and  $\text{CS}_2$  the mols. of I are doubled, while in  $\text{CCl}_4$  its mol. wt. is normal, these results differing from those of Timofeev.

CHAS. BLANC

The distribution law. III. Application of the van Laar distribution law to a con-

densified system of molten metals. RICHARD LORENZ AND GEORG SCHULZ. Univ. Frankfurt a.M. *Z. anorg. allgem. Chem.* 179, 339-44(1929); cf. *C. A.* 23, 2633.—The distribution law for condensed systems,  $(x/y)^{\omega} = K$ , has been applied to the data obtained for the distribution of Ag between molten Pb and Al. In this form the ratio is expressed in mol. fractions and  $\omega$  represents a complex function of the van der Waals consts.,  $a$  and  $b$ . The function is composed of 2 parts, 1 of which is detd. empirically and the other of which is calcd. from known values of  $a$  and  $b$ . The results show that the formula is valid over the range from 0.9 to 30 at. percent of Ag in the Al phase. Satn. exists in this phase at 60 at. % Ag. H. F. JOHNSTONE

Voltage effect of electrolytic conductance in very strong fields. MAX WIEN. *Ann. Physik* [5], 1, 400-16(1929); cf. *C. A.* 22, 3088.—Limiting tension effects and concn. effects were detd. for  $K_3Fe(CN)_6$ ,  $Li_3Fe(CN)_6$ ,  $K_4Fe(CN)_6$ ,  $MgCrO_4$ ,  $MgSO_4$ ,  $Ba_2[Fe(CN)_6]_2$ ,  $Ba_2Fe(CN)_6$ . Three solns. of each salt were examd. Their sp. conds. were resp.:  $2.3 \times 10^{-8}$ ;  $4.6 \times 10^{-8}$ ;  $9.2 \times 10^{-8}$ . For these solns. the limiting tension effect agrees with the concn. effect. For ions of low valence, values calcd. on the basis of the Debye-Onsager theory agree with expt. results. The influence of assocn. did not make itself felt in the case of these highly dil. solns. FRANK URBAN

Exact calculation of the Wien difference of potential effect ("Spannungseffekt") in electrolytes. M. BLUMENTRITT. *Ann. Physik* [5], 1, 195-215(1929).—Wien observed a rise in the cond. of electrolytes with the applied voltage (cf. *C. A.* 22, 906). This has been discussed by Joos, by B., and by J. and B. (cf. *C. A.* 22, 4325, 3088, 2861). This "Spannungseffekt" is now computed according to L. Onsager's modification of the Debye-Hückel theory, which includes a consideration of the effects of the Brownian movement (cf. *C. A.* 21, 2412). This takes care of certain discrepancies that appeared in the earlier work. With these modifications the results calcd. by the present theory show excellent agreement with expt. for the "Spannungseffekt" up to fields of 25,000 v./cm. W. W. STIFLER

The electrical conductivity of hydrochloric, hydrobromic and hydriodic acids and the mobility of the hydrogen ion. M. HLASKO AND D. WAZEWSKI. Wilno Univ. *Bull. intern. acad. Polonaise* No. 4-5A, 181-90(1928).—In general acids that are hydrides of various elements increase in strength as one descends a column of the periodic table. This investigation shows that the acids HCl, HBr and HI are no exception to the rule. The authors det.  $\lambda_{\infty}$  for HCl, HBr and HI as 431.5, 433.7 and 432.3, resp. These values together with their value for the mobility of the H ion, viz., 355.1, are notably larger than those usually given. In dil. solns. the relative strengths of the acids are  $HI > HBr > HCl$ , but in very concd. solns. the reverse is the case, HCl having the largest degree of dissociation, a circumstance that is explained by the rule of Nernst and of J. J. Thomson by taking into account the changed dielec. const. of the medium. The densities and viscosities of aq. solns. of these acids are given. The viscosities diminish in the order HCl, HBr, HI. R. E. GIBSON

Conductivity of electrolytes for high-frequency currents. H. RIECKHOFF AND H. ZAHN. *Z. Physik* 53, 619-27(1929).—The theory of Debye and Falkenhagen (*C. A.* 22, 3573) concerning the cond. of electrolytes for high-frequency currents is tested exptly. and found satisfactory for a number of electrolytes over a large range of concn. However with concd. solns. the agreement is only approx. For a completely dissociated electrolyte having two ions,  $\lambda$  the mol. cond. is given by:  $\lambda = \lambda_{\infty} - (\lambda_1 + \lambda_2)\sqrt{\gamma}$ , where  $\lambda_{\infty}$  is the cond. at infinite diln.,  $\lambda_2$  is the decrease in mol. cond. caused by the increased Stokes' friction force due to the ion atm. and  $\lambda_1$  is due to the dissymmetry of the ion atm. relative to the ion when moving under the elec. field;  $\gamma$  = concn. in moles per l. GEORGE GLOCKLER

Relation of the electric conductivity and the vapor pressure of solutions. TH. DAHLBLOM. *Tek. Tid., Uppl. C, Kemi* 58, 76-9(1928).—The following equation was calcd. from the detns. of elec. conductivity and vapor pressure published in the tables of Landolt-Börnstein-Roth:  $K \log(p_0/p) + rC = nF$ , where  $K$  is a const. dependent on the temp. of the soln.,  $p_0$  is the vapor pressure of  $H_2O$ ,  $p$  that of the soln.,  $r$  is a const. specific for the dissolved substance,  $C$  the elec. cond. of the soln.,  $n$  the concn. in mols. per 100 g.  $H_2O$  and  $F$  a const. specific for the dissolved substance and considered by the author as in a certain way expressing the relationship of the substance to the solvent. At  $0^\circ K = 3060^\circ$ . For NaCl in  $H_2O$  at  $0^\circ$  the equation  $3060 \log(4.579/p) + 685 C = n 75.5$  agrees with the exptl. facts from very dil. to satd. soln. From the detns. of Kohlrausch (cond.) and Dieterici (vapor pressure) the following values of  $r$  and  $F$  are calcd.: for KCl, resp., 710 and 87; for NaCl 685 and 75.5; LiCl 1560 and 105;  $CaCl_2$  1920 and 207. From the detns. of vapor pressure at  $100^\circ$  by Tamman and elec. cond. at  $100^\circ$  by the author  $K$  is calcd. as 3926 and the values of

and  $F$  for  $\text{CdSO}_4$  as, resp., 87 and 25.5; for  $\text{MnSO}_4$  186 and 34;  $\text{ZnSO}_4$  428 and 55;  $\text{MgSO}_4$  550 and 63;  $\text{Na}_2\text{CO}_3$  76 and 75;  $\text{KOAc}$  245 and 98;  $\text{K}_2\text{CO}_3$  311 and 149.

C. A. ROBAK

The potential of inert electrodes in solutions of sulfurous acid and its behavior is an oxidizing and reducing agent. ARTHUR A. NOYES and HAROLD H. STEINOUR. Calif. Inst. of Tech. *J. Am. Chem. Soc.* 51, 1409-28(1929).—Measurements were made of the e. m. f. against the molal H electrode of platinized electrodes in solns. of  $\text{H}_2\text{SO}_3$ . From a study of the effect of electrode treatment, agitation,  $\text{SO}_2$  and  $\text{O}_2$  partial pressure, the presence of S and of  $\text{H}_2\text{S}_2\text{O}_8$ , and the H-ion concn., it is concluded that the fairly definite e. m. f. of  $-0.37$  volt is due to an equil. between  $\text{H}_2\text{SO}_3$  and  $\text{H}_2\text{S}_2\text{O}_4$  (which N. and S. propose to call "dithionous" acid). Toward compds. with a more negative potential,  $\text{H}_2\text{SO}_3$  acts as an oxidizing agent; toward those with a potential more positive than  $-0.14$  volt, it acts as a reducing agent; for intermediate values, it may be either, but generally oxidizing (cf. Carter and James, *C. A.* 19, 771).

T. H. CHILTON

The colorimetric measurement of hydrogen-ion concentration in very weakly buffered solutions. ERIK ÖMAN. *Papier-Fabr.* 27, 27-30(1929).—The  $p_H$  value obtained by indicators in a weakly buffered soln., such as distd.  $\text{H}_2\text{O}$ , varies with the amt. of indicator used. Measurements may be made with several known vols. of indicator, making comparison with standard buffers contg. the same amt. of indicator as used in the several samples. Then by plotting the cc. of indicator vs.  $p_H$  a smooth curve is obtained which upon extrapolation gives the true  $p_H$  (with 0 cc. of indicator). The same method may be applied with a common color comparator by using 0.5, 1 and 2 times the standard vol. of indicator and making observations through, resp., 2, 1 and 0.5 times the standard thickness of soln. The accuracy of the result is limited only by the accuracy of the several detns.

R. H. DOUGHTY

The influence of neutral salts on acid-base equilibria. V. First and second dissociation constants of succinic acid, tartaric acid and adipic acid and the influence of neutral salts on the  $p_H$  of a mixture of the acid and its acid salt, and the acid salt and normal salt, respectively. I. M. KOLTHOFF and W. BOSCH. *Rec. trav. chim.* 47, 861-72 (1928); cf. *C. A.* 22, 4316.—The following values have been found from  $p_H$  measurements for the first and second dissocn. const. of the three dibasic acids: succinic,  $6.6 \times 10^{-5}$  and  $2.7 \times 10^{-6}$ ; adipic,  $4.6 \times 10^{-5}$  and  $3.6 \times 10^{-6}$ ; tartaric,  $9.6 \times 10^{-4}$  and  $2.8 \times 10^{-5}$ . The results are extrapolated for infinite diln. Neutral salts increase the activity of the undissocd. acid. The dissocn. const. of the acid is not increased. The Debye-Hückel equation does not completely represent the effect of neutral salts on the ratio of the activity coeffs. of the univalent and bivalent anions of the weak dibasic acid. The sp. ionic interaction must be taken into account. VI. Dissociation constants of acetic, caproic and benzoic acids and the influence of neutral salts on the dissociation constants of weak acids. *Ibid* 872-82.—The dissocn. const. of the 3 monobasic acids at  $18^\circ$  are: acetic,  $1.7 \times 10^{-5}$ ; caproic,  $1.44 \times 10^{-5}$ ; benzoic  $7.0 \times 10^{-6}$ . In this case also there is no evidence that neutral salts increase the dissocn. const. of weak acids.

B. C. A.

The change of potential in acid-alkali titrations and the determination of ionization constants. F. L. HAHN. *Ber.* 62B, 727-36(1929).—The ratio  $\Delta\epsilon_{\text{max}}/\Delta v$  where  $\epsilon$  is the potential and  $\Delta v$  the volume of reagent added, can be used for the detn. of ionization const. The accuracy attainable is about  $\pm 10\%$  for univalent acids and bases,  $\pm 20\%$  for bivalent ones and  $\pm 30\%$  for ampholytes.

FRANK URBAN

Amphoteric hydroxides, their aqueous solutions and crystallized salts. VII. The reaction of stannates in aqueous solution by change of hydrogen-ion concentration with hydrochloric acid. GERHARD JANDER, FRANZ BUSCH and THEODOR ADEN. Univ. Gottingen. *Z. anorg. allgem. Chem.* 177, 345-62(1928); cf. *C. A.* 21, 3522.—Pptn. occurs between  $p_H$  0.9 and 11.6. Just below 11.6 hydrolysis either results in pptn. of all of the Sn or attainment of the upper limit. Addn. of HCl results in soln. of the ppt at the lower limit. Alk. stannates or those that have hydrolyzed to  $p_H$  11.6 show no absorption between 220 and  $700\mu$ . A  $0.1 M \text{Na}_2(\text{Sn}(\text{OH})_6)$  and  $0.02 N$  HCl mixt. gives strong absorption starting about  $300\mu$ . Further addn. of HCl including complete soln. makes no characteristic change in the absorption but the intensity increases. In  $5 N$  HCl soln. absorption above  $300\mu$  increases. In strongly acid solns. at least 3 different compds. of  $\text{Sn}^{++++}$  are present. Addn. of  $\text{Na}_2(\text{Sn}(\text{OH})_6)$  soln. to Cu salts in  $\text{NH}_3$  soln. of  $p_H$  11.5-12.0 gives  $\text{Cu}(\text{Sn}(\text{OH})_6)$ . Ni behaves similarly. No  $\text{Cu}(\text{Sn}_2(\text{OH})_{10})$  was found. Probably in  $5 N$  HCl  $\text{SnCl}_4$  is present. With decreasing  $\text{H}^+$  concn. this forms  $\text{SnOCl}_2$ . Going toward greater alkalinity a compd. of lower Cl and higher OH is probably formed before  $\text{Na}_2(\text{Sn}(\text{OH})_6)$  is reached.

FOSTER DEB SNELL

**Reactions in liquid hydrogen sulfide. VI. Reactions with organic compounds.** R. W. BORGESSON AND J. A. WILKINSON. *Iowa State Coll. J. Am. Chem. Soc.* **51**, 1453-6(1929); cf. *C. A.* **23**, 2092.—Reactions with the following types of org. compds. were studied: satd. hydrocarbons, unsatd. hydrocarbons, alcs., phenols, ethers, amides, ketones, alkyl and aryl halides, acids, acid anhydrides, esters, sugars, nitro compds., Grignard reagent, aldehydes, amines and acyl halides. The substances were cooled to  $-77^\circ$ , liquid  $H_2S$  was added, and the tubes were sealed and allowed to come to room temp. After several weeks the tubes were cooled, opened,  $H_2S$  was evapd. and residues were examd. Several compds. of each type were studied. Qual. solubilities are given. The presence of a double bond is usually shown by mercaptan formation. The last 3 types named are the only ones that show much evidence of reacting with liquid  $H_2S$ . There are 10 references.

GERALD M. PETTY

**Curves of thermodynamic potentials of alloys in the region of formation of chemical compounds.** A. B. MLODZHEVSKII. *Ann. inst. anal. phys.-chim. (Leningrad)* **4**, 247-81 (1928).—It is shown mathematically that the existence of a sharp point (which detd. the presence of a nondissocd. compd.) on the m. p. curves of binary alloys is detd. by the discontinuity of the curves of the thermodynamic potential of the liquid phase. The non-dissocd. compd. must be considered as a new substance which is independent of the original components of the alloy.

V. KALICHEVSKY

**The velocity of decomposition of potassium persulfate in aqueous solution.** ANTON KAILAN AND LUDWIG OLBRIICH. *Monatsh.* **47**, 449-84(1927).—Using the method of Green and Mosson (*C. A.* **5**, 820), the authors studied the velocity of decompn. of  $K_2S_2O_8$  at  $25^\circ$  both alone and in the presence of  $H_2SO_4$ . They also studied the reaction at  $99^\circ$  alone and in the presence of  $K_2SO_4$ ,  $HNO_3$ ,  $H_3PO_4$  and  $H_2SO_4$ . The results indicate a unimol. reaction and agree quant. with previous work. The speed of the reaction is sensitive to ionic influences; in particular  $H^+$  and  $NO_3^-$  ions accelerate the reaction while  $SO_4$  and  $K^+$  ions retard it. Decrease in the partial pressure of  $O_2$  over the soln. does not increase the velocity of the reaction and so the effect of substances like toluene which accelerate the reaction is not due to oxidation. R. E. G.

**The constant of mass action.** R. F. GOLDSTEIN. *Phil. Mag.* [7], **7**, 205-6(1929); cf. *C. A.* **22**, 4040.—Kleeman (*C. A.* **22**, 1888) failed to consider the free energy decrease in the dissocn. of the mol. species which would dissoc. after passing the semipermeable membrane. If this is taken into account the const. of mass action reduces to the simple van't Hoff form.

L. H. REYERSON

**The constant of mass action.** R. D. KLEEMAN. *Phil. Mag.* [7], **7**, 206-8(1929); cf. preceding abstr.—A new deduction of K.'s previous results is given. The usual deduction of the van't Hoff cycle does not take into account assocn. or dissocn. in the mixt. which must follow the removal of a mol. species.

L. H. REYERSON

**Equilibrium in the system: methanol-hydrogen-carbonic oxide.** D. M. NEWITT, B. J. BYRNE AND H. W. STRONG. *Proc. Roy. Soc. (London)* **A123**, 236-52(1929).—Equil. in the system:  $CH_3OH-H_2-CO$ , was approached from both sides by static and dynamic methods. Total pressures of the order of 100 atms. were measured by movement of a disk observed by optical methods. The compn. at equil. was detd. by gas analysis. Partial pressures were calcd. assuming no deviation from Boyle's law. The results from  $260^\circ$  to  $380^\circ$  are not in agreement with prediction for the equil. position made by Kelley or by Audibert and Raineau. The free-energy equation derived from the measurements is  $\Delta F = 70.5T - 30,500$ .

G. B. TAYLOR

**The iron-water system.** G. SCHIKORR. *Z. Elektrochem.* **35**, 62-5(1929).—An equil.  $H_2$  pressure of 190 mm. Hg is calcd. from electrochem. data for the reaction  $Fe + 2HOH \rightarrow Fe(OH)_2 + H_2$ . Exptl. data show that pressures up to 5.8 atm. are developed by the iron-water system and evidence is given that the  $H_2$  is generated by the oxidation of  $Fe(OH)_2$  to  $Fe_2O_3$ .

J. G. McNALLY

**Acid and salt effects in catalyzed reactions. XIX. Catalytic activity of chloroacetic acid in the hydrolysis of ethyl acetate.** HARRY M. DAWSON AND WM. LOWSON. *Univ. Leeds. J. Chem. Soc.* 1929, 393-401; cf. *C. A.* **23**, 2093.—An investigation was made of the catalysis by chloroacetic acid of the hydrolysis of EtOAc in the presence of varying amts. of Na chloroacetate. Since there were previous indications of catalysis of this reaction by both the AcOH mol. and the acetate ion (*C. A.* **22**, 716) and since, in the equation,  $v = k_a[H^+] + k_s[A^-] + k_m[HA]$ ,  $k_m$  increases and  $k_a$  diminishes with increase in the ionization constant,  $K$ , of the catalyzing acid, it was expected that catalysis by the chloroacetic acid mol. could be easily demonstrated. However, the formation of HCl by hydrolysis of the chloroacetate places a limit on the amt. of chloroacetate that can be added to reduce the concn. of  $H^+$  to the point where the velocity of hydrolysis of the EtOAc will not be dominated by its effect. Also, the increase

in  $k_m$ , in replacing AcOH by chloroacetic acid, is much less than the increase in  $K$ . Further,  $k_m/k_h$  for chloroacetic acid is about  $1/35$  the value in the acetone-iodine reaction. Consequently, the detn. of  $k_m$  for the ester hydrolysis is complicated by "inert salt effects." Expts. were made at  $25^\circ$  on solns. contg. 20 cc. (0.206  $M$ ) of EtOAc per l. With 0.1  $N$  chloroacetic acid and 1.0  $N$  chloroacetate, and with 0.05  $N$  chloroacetic acid and 0.50  $N$  chloroacetate, no evidence could be found of catalytic activity by the chloroacetic anion. Hence, the catalytic effect of chloroacetic acid can be expressed by the equation,  $v = k_h[H^+] + k_m[HA]$ , when provision is made for the effects of ionic environment on  $k_h$  and  $K$ . The dependence of  $k_h$  on the reaction medium was detd. from reaction velocity measurements in NaCl solns. with 0.01  $N$  HCl as catalyst. Variations in  $K$  were detd. by combining these last expts. with a corresponding series with 0.1  $N$  AcOH as catalyst. The value of  $k_h$  increases linearly up to 2  $M$  NaCl.  $K$  passes through a max. at about 0.5  $M$  NaCl. When the total ion concn. is kept const., the catalysis by free chloroacetic acid and its mixts. with chloroacetate can be satisfactorily explained on the basis of fixed values for  $K$ ,  $k_h$ , and  $k_m$ .  $k_m = 0.09 \times 10^{-4}$ .  $k_m/k_h =$  about  $1/700$ .  $K$  may be taken as  $1.5 \times 10^{-3}$  in very dil. solns.

MERRILL W. SEYMOUR

An investigation of the combustion of platinum. ERIC K. RIDGAL AND O. H. WANSBROUGH-JONES. *Proc. Roy. Soc. (London)* A123, 202-16(1929).—The kinetics of the reaction between  $O_2$  at pressures 5-200 bars on Pt wires at  $1600$ - $1900^\circ$ .  $K$  is shown to comprise a surface reaction proportional to the pressure and a zero-order gas-phase reaction with Pt vapor. The energy of activation of the surface reaction is found to be 2.75 v. The product of reaction is  $PtO_2$ .

G. B. TAYLOR

The reaction kinetics in a macro-heterogeneous medium. ST. J. V. PRZYBYCKI. *Biochim. Z.* 206, 60-98(1929).—A very extensive theoretical discussion. S. M.

Fusion curves represented in a special system of coördinates. N. V. LIPIN. *Ann. inst. anal. phys.-chim. (Leningrad)* 4, 59-64(1928).—The relationship between the compn. of a binary mixt. and its fusion temp. is derived from the fusion equation of Shreder (*Gornui Zhurnal* 1890, No. 11, 272) and represented in two special systems of coördinates.

V. KALICHEVSKY

Reaction limits, reaction regions, and reaction spaces. W. P. JORISSEN. Univ. of Leiden. *Chem. Reviews* 6, 17-43(1929); cf. *C. A.* 23, 753.—Ternary and quaternary systems of gases and of solids are reviewed with special emphasis on their graphical representation.

ARTHUR FLEISCHER

Heterogeneous equilibrium at  $97^\circ$  in systems which contain water, sodium sulfate, and sulfates of bivalent metals. A. BENRATH AND H. BENRATH. *Z. anorg. allgem. Chem.* 179, 369-78(1929); cf. *C. A.* 22, 903, 4040; 23, 1343.—Study of heterogeneous equilibria by the analytical method at  $97^\circ$  shows the following solid phases in equil. with soln. contg.  $Na_2SO_4$  and a sulfate of a bivalent metal:  $ZnSO_4 \cdot H_2O$ - $ZnSO_4$ ,  $Na_2SO_4 \cdot 4H_2O$ - $ZnSO_4$ ,  $3Na_2SO_4$ - $Na_2SO_4$ ,  $CdSO_4 \cdot H_2O$ - $CdSO_4$ ,  $Na_2SO_4$ - $CdSO_4$ ,  $3Na_2SO_4$ - $Na_2SO_4$ ,  $FeSO_4 \cdot H_2O$ - $FeSO_4$ ,  $Na_2SO_4$ ,  $2H_2O$ - $FeSO_4$ ,  $3Na_2SO_4$ - $Na_2SO_4$ ,  $CoSO_4 \cdot H_2O$ - $CoSO_4$ ,  $Na_2SO_4$ ,  $4H_2O$ - $Na_2SO_4$ ,  $NiSO_4 \cdot 6H_2O$ - $NiSO_4$ ,  $Na_2SO_4$ ,  $4H_2O$ - $Na_2SO_4$ ,  $CuSO_4 \cdot 3H_2O$ - $CuSO_4$ ,  $Na_2SO_4$ ,  $2H_2O$ - $Na_2SO_4$ ,  $MgSO_4 \cdot H_2O$ - $MgSO_4$ ,  $Na_2SO_4$ ,  $2H_2O$ - $MgSO_4$ ,  $3Na_2SO_4$ - $Na_2SO_4$ . The systems contg. Fe and Cu were investigated in dil.  $H_2SO_4$  soln.

R. J. HAVIGHURST

The reaction between iron, iron oxides and water. G. SCHIKORR. *Z. Elektrochem.* 35, (65-70)(1929).—When  $Fe(OH)_3$  is heated with Fe and water, it becomes black and  $H_2$  is generated. Evidence is given that the dark color is caused by the formation of  $Fe_3O_4$  obtained by reducing  $Fe_2O_3$ . The  $H_2$  is formed by the oxidation of  $Fe(OH)_3$  to  $Fe_2O_3$ . The velocity of formation of  $H_2$  is inversely proportional to the cube root of the  $H_2$  pressure on the system, and the rate is doubled by an increase in temp. from  $25^\circ$  to  $35^\circ$ .

J. G. McNALLY

The oxidation of copper at higher temperatures. W. FRITKNECHT. Bern. *Z. Elektrochem.* 35, 142-51(1929).—At higher temps. the rate of oxidation of Cu follows the law  $x^2 = Kt$  after the reaction is well under way; during the early stage of the reaction the rate of oxidation is faster than the equation indicates.  $K$  diminishes faster with fall of temp. than is required by the theoretical equation  $K = Ae^{-E/RT}$ . In oxidations by means of mixts. of  $O_2$  with  $N_2$  and  $CO_2$ , the velocity const. is independent of the partial pressure of  $O_2$  up to the dissozn. pressure of CuO and thereafter diminishes approx. proportionally to the log of  $O_2$  pressure. The oxide layer formed consists of  $Cu_2O$ , with a superficial layer of CuO. This is thickest at medium temps. The  $Cu_2O$  has a metal-like structure. It shows crystal growth which follows the same rules as do metals. The diffusion of  $O_2$  occurs through the crystallites and along the crystallite boundaries. The discrepancy between the exptl. results and the theory is a conse-

quence of the crystal growth of the  $\text{Cu}_2\text{O}$  and the marked decrease in crystallite size with falling temp.

The specific heat of superheated steam at pressures from 30 to 120 atmospheres and from saturation temperatures to  $450^\circ$ . OSCAR KNOBLAUCH AND W. KOCK. *Z. Ver. deut. Ing.* 72, 1733-9(1928); *Mech. Eng.* 51, 147-50(1929); *Naturwissenschaften* 17, 269-70.—By use of an adiabatic flow calorimeter,  $C_p$  for steam has been measured from satn. to  $450^\circ$  and from 30 to 120 atms. At const. pressure the sp. ht. increases rapidly as satn. is reached. Full tables are given.

The properties of the thermodynamic diagram relative to the saturated vapor. G. BRUHAT. *Compt. rend.* 187, 529-31(1928).—The isochores, plotted on an entropy-temp. diagram undergo an abrupt change of direction in crossing from the liquid to the gas phase. The angle thus made is calcd.

Reduction in entropy of a thermodynamic system caused by the interference of intelligent beings. L. SZILARD. *Z. Physik* 53, 840-56(1929).—It was usually stated that the second law of thermodynamics could be violated by a Maxwell demon. S. considers entropy changes of some simple thermodynamic systems which are being interfered with by intelligent beings or their equivalents. Conclusion: Their acts of interference cause in themselves an entropy increase that is exactly equal to the entropy decrease produced in the system by their interference.

The individuality of heats of dilution of strong electrolytes. E. LANGE AND J. MEIXNER. *Naturwissenschaften* 17, 273-4(1929).—Recent measurements on  $\text{LiF}$  and  $\text{KNO}_3$  have shown that the integral heats of diln. ( $C. A.$  23, 1046, 1562)  $V_e$  of strong electrolytes show individual differences even below 0.01  $N$  concn. for uni-univalent salts. The  $V_e$  values ( $\text{LiF} > \text{KF}$ ,  $\text{LiF} > \text{LiBr}$ ,  $\text{KF} > \text{KCl} > \text{KNO}_3$ ,  $\text{KCl} > \text{CsCl}$ ) are larger for smaller ion diams.,  $a$ , ( $\text{Li} < \text{K} < \text{Cs}$ ;  $\text{F} < \text{Cl} < \text{Br} < \text{NO}_3$ ); the  $V_e$  of  $\text{LiF}$  and of  $\text{CaSO}_4$  is larger than required by the Debye-Hückel law (with  $a = 0$ ) for  $dD/dT = -0.337$ . Even with introduction of a finite  $a$  and  $da/dT = 0$  the value of  $V_e$  from  $-0.239 \times 10^{-7} \sum \nu_i z_i^2 (Ne^2/2D) [x/(1 + ax) + (T/D)(dD/dT)]$  can only give individual deviations downward for  $V_e$ . For pos. deviations neg.  $a$  values would be required. A new law analogous to the one of Gronwall, LaMer and Sandved (*C. A.* 22, 3334) including higher members of the activity function was derived for  $\pm 2$

valent electrolytes with  $a_{\text{kat.}} = a_{\text{an}} = a$  in the form  $V_e = RT \left[ \sum_{m=1}^{\infty} (e^2 z^2 / D a k T)^{2m} - 1 \right]$ .  $X_{2m} - 1 - (e^2 z^2 / D a k T) [1 + (T/D)(dD/dT)]$  cal. per mole. The factors  $X$  are those of G. L. and S.,  $da/dT = 0$ ,  $dD/dc = 0$ ,  $D_{25} = 79$  are assumed. Graphically this law means that for very low concns. ( $c < 10^{-4} N$ ) the Debye-Hückel law is followed ( $a = 0$ ) asymptotically. For little higher concns. ( $c > 0.00025 N$ ) experimentally significant, plus or minus deviations are to be expected, depending on the value of  $a$ . For increasing  $a$  the law approaches the Debye-Hückel law with finite  $a$ . Neg.  $V_e$  values cannot be explained by the new expression. Various curves are given for  $a$  from 0.8 to 10 Å. U. in fair agreement with values for different salts. For  $\text{CaSO}_4$  the  $V_e$  curve appears to approach at low concn. the required limit. Neg. tendencies of some  $V_e$  curves ( $\text{KNO}_3$ , specially) might perhaps be due to  $dD/dc \neq 0$ ,  $da/dT \neq 0$  or by the influence of heat of disson.

Heat of fusion (and specific heat) allylphenylthiourea. V. P. SHISHOKIN. *Ann. inst. anal. phys.-chim.* (Leningrad) 4, 183-94(1928).—Sp. heats of liquid and solid  $\text{CS}(\text{NH}_2\text{C}_6\text{H}_5)(\text{NH}_2\text{C}_6\text{H}_5)$  are 0.423 and 0.335, resp., and the heat of fusion is  $6600 \pm 100$  cal. per mol.

The limiting value of the latent heat of vaporization. J. E. VERSCHAFFELT. *Z. physik. Chem.*, Abt. A, 140, 64(1929).—A rejoinder to Kolossowsky's interpretation of V.'s results (*C. A.* 22, 4337).

The heat capacity of hydrogen iodide from  $15^\circ \text{K.}$  to its boiling point and its heat of vaporization. The entropy from spectroscopic date. W. F. GIAUQUE AND R. WIERB. Univ. Calif. *J. Am. Chem. Soc.* 51, 1441-9(1929); cf. *C. A.* 22, 719, 3570.—Entropies for the gaseous state calcd. from spectroscopic data agree within the exptl. error with those calcd. from calorimetric data. Transition points were found at about  $70^\circ$  and  $125^\circ \text{K.}$  The m. p. is  $222.31 \pm 0.05^\circ \text{K.}$  and the b. p. is  $237.75 \pm 0.05^\circ \text{K.}$  The heat of fusion is  $686.3 \pm 0.8$ , and the heat of vaporization is  $4724 \pm 5$ . The entropy of the gas is  $47.8 \pm 0.1 \text{ E. U.}$  at the b. p. There are 17 references.

### 3—SUBATOMIC PHENOMENA AND RADIOCHEMISTRY

S. C. LIND

**Behavior of the radioactive deposit during operations for the determination of the emanation in water.** HENRYK HERSZFINKIEL. *Roczniki Chem.* 8, 519-25 (Polish), 525-6 (German) (1928).—The expts. of Hammer and Vohsen (*C. A.* 7, 2902) and of Engler, Sieveking and Koenig (*C. A.* 8, 2527, 3267) were repeated and it was found that the radioactive deposit in water was not liberated at concns. below 0.01%. Moreover the deposit seps. on to the walls of the vessel on shaking, boiling and by air passage and this also takes place in the state of rest, only more slowly. This behavior agrees with similar observations of Lachs and Wertenstein (*C. A.* 16, 3805). Even by an enormous diln. of radioactive ppt. in H<sub>2</sub>O, the ppt. does not appear in the gaseous state.

**The structure of atoms.** FELIX JOACHIM V. WISNIEWSKI. *Physik. Z.* 29, 716-21 (1928).—The paper represents an attempt to produce a picture of the structure of an atom on the basis of the assumption that every single atom contains an energy level *K*, one of the energy levels *L*, one of 5 energy levels *M*, etc., by substituting for these energy levels those corresponding to individual electrons of the electron orbits. Satisfactory results have been obtained for the energy levels *K*; *L*<sub>I</sub>, *L*<sub>II</sub>, *L*<sub>III</sub>; *M*<sub>II</sub>, *M*<sub>III</sub>, *M*<sub>IV</sub> and *M*<sub>V</sub>.

**The significance of atom models.** A. SOMMERFELD. *Z. Elektrochem.* 34, 426-30 (1928).—Historical review.

**Atomic nuclei and their changes.** E. RUTHERFORD. *Apoth. Ztg.* 44, 577-8 (1929).—An address given before the Ger. Chem. Soc.

**Thermal equilibrium of dissociation of atom nuclei.** SEITARÔ SUZUKI. *Proc. Phys.-Math. Soc. Japan* [3], 10, 166-9 (1928).—The formation of a He nucleus from 4 protons can be treated as an ordinary reversible chem. combination and the Sackur-Tetrode equation applied to it. The result of the computation indicates that dissoen. of He nuclei should take place at  $2.1 \times 10^9$  degrees and pressures between 10 and 0.1 atm. No star has been observed where He is thermally dissociating into protons.

**Significance of the packing fraction.** MARCEL FRANCON. *J. Phys. Chem.* 33, 296-300 (1929).—It is pointed out that the packing fraction (a term introduced by Aston to designate the divergence of the mass no. of an atom from a whole no., divided by the mass no.) is of utmost importance in estg. the energy emitted or absorbed in formation of the elements, and in formulating theories of nuclear structure. Curves given by Aston (*C. A.* 21, 3543) illustrating the variations of packing fractions with mass nos. show that the nucleus has a structure very different from the arrangement of planetary electrons. Cosmological speculations may be drawn from this quantity; thus ele-

ments tend to the formation of other elements for which the packing fraction is as small as possible. H. R. MOORE

**A theoretical expression for the life of the atom in the metastable state.** MEGHNAD SAHA AND D. S. KOTHARI. Univ. Allahabad. *Naturwissenschaften* 17, 271(1929). (In English.)—The life of the excited atom in metastable state has been previously found to be  $T = 3 mc^3/8 \pi^2 e^2 \nu^2$ , of the order  $10^{-8}$  sec. for  $\nu = 10^4 c$ . From the fact that during transitions between metastable states only the magnetic moment of the atom changes and that it can therefore be compared to a closed oscillator, it is derived that the life of an atom in the metastable state is roughly  $T = 3 c^4 m^2 / \pi^2 e^2 h \nu^3$ . This equation gives a value of  $T = 1.5 \times 10^{-1}$  sec. for  $\nu = 10^4 c$ , which is of the correct order of magnitude. B. J. C. VAN DER HOEVEN

**Application of the Pauli-Fermi electron gas theory to the problems of cohesion forces.** YA. FRENKEL. Leningrad. *Z. Physik* 50, 234-48(1928).—This is a mathematical paper in which F. discusses the kinetic energy pressure of an electron gas from the standpoint of relativistic mechanics, and shows that condition for min. energy, which detcs. the state of a mech. system at abs. zero, applied to the Pauli-Fermi metal model, is equiv. to the virial law. The Thomas-Fermi relation for the dependence of electron concn. on potential energy at  $T = 0$  is deduced on the basis of the min. energy principle. The inner structure of at. nuclei is considered. F. shows that an extremely high pressure may possibly cause, even at abs. zero, such a sepn. of electrons from individual nuclei, that the entire mass may be visualized as the mixt. of electrons and nucleus gas, and discusses the structure of stars from this viewpoint. R. L. H.

**Transition probabilities in lithium atoms. II.** B. TRUMPY. Trondhjem. *Z. Physik* 50, 228-33(1928).—T. shows how the method of Schrödinger-Sugiura may be applied to the calcn. of the transition probabilities of the quantum jumps  $2_2 - 2_1$  and  $3_2 - 2_1$  of the Li atom. The values of  $f$  are 0.7230 and 0.0642, resp. By using the exptl. relation, obtained previously (C. A. 21, 3827),  $a_{ki} \sim 1/n^3$ , where  $n$  is the variable quantum number, the  $f$  values for the remaining quantum jumps of the principal series are calcd. and thus  $\Sigma f$  for the continuous part of the absorption is detd.  $\Sigma f$  is 0.171. R. L. H.

**The radiation from atoms.** J. KLEIBER. *Ann. Physik* 87, 461-8(1928).—K. discusses the classical and Bohr theories as regards radiation from atoms and presents a new method of deriving the Balmer formula. R. L. HERSHEY

**A further optical contribution to the investigation of the atomic structure of helium.** J. STARK. *Ann. Physik* 87, 927-34(1928).—A study of the action of an elec. field on He lines bears out S.'s earlier theory (C. A. 22, 3582) that the structure of certain elements possess designated axes. Thus the series components of He, the alkalis and alkaline earths are analogous to H lines in an elec. field. For He, fields of 300,000-555,000 v./cm. give rise to the para series lines  $2P_2 - mP_2$  and the ortho series lines  $2p_2 - mp_2$ . These ortho and para lines lie on opposite sides of the zero line. With regard to the 1S state of He, the magnetic moment of the electron giving rise to the para series is opposed to the magnetic moment of the second electron. H. R. M.

**The nature of cosmic radiation.** W. BOTHE AND W. KOLHÖRSTER. *Naturwissenschaften* 17, 271-3(1929).—Expts. lead to the conclusion that the cosmic radiation is not  $\gamma$ -radiation but is of corpuscular nature. This conclusion necessitates revision of many previous theories. It is only suggested that electrons penetrating the atmosphere at the required speed must have an energy of at least  $10^8$  e v. B. J. C. v. H.

**Absorption in lead, secondary rays and wave lengths of cosmic rays.** I. MISSEVSKII AND I. TUVIM. *Z. Physik* 50, 273-92(1928).—The absorption of cosmic rays by Pb under exptl. conditions similar to those with  $H_2O$  has been detd. The electroscopie was placed within a pile of Pb blocks, the dimensions of the pile being varied. Primary cosmic rays are absorbed in Pb, as in  $H_2O$ , by scattering without noticeable photo effects. In order to study the steep part of the absorption curve, which is in the region of the smaller Pb piles, the electroscopie was placed in a large ice block and the absorbing Pb placed either within or upon the ice block. These expts. showed that the steep drop in the absorption curve in the neighborhood of the boundary of air or ice is due to a scattered radiation, similar to  $\gamma$ -rays, which has considerable photo effect when absorbed in Pb. The results obtained show that the method of calcn. of wave length of cosmic rays by assuming that the absorption coeff. agrees with the scattering coeff. is correct. The wave length reported is  $4.4 \times 10^{-4}$  A. U. R. L. HERSHEY

**Cosmic rays and a cyclic universe.** EDMUND C. STONER. Univ. Leeds. *Proc. Leeds Phil. Lit. Soc., Sci. Sect.* 1, 349-55(1929).—A theoretical discussion on the relative merits of Millikan's (C. A. 22, 1900) and Jeans' (C. A. 23, 1048) interpretation of the nature of cosmic rays and a cyclic system for the universe. S. questions the atom-

upbuilding from electrons and protons and believes the universe is running down through an irreversible transmutation.

Optical method for analyzing  $\alpha$ -ray tracks. L. F. CURTISS. *Nature* 123, 520 (1929).—A double camera (= 2 cameras placed at right angles) take 2 views of an  $\alpha$ -ray track simultaneously on sep. negatives. In order to secure a full-sized image of the  $\alpha$ -ray track it is only necessary to replace the developed negatives in the camera and project them on the focal plane. By adjusting a thin translucent screen a position is found where no part of the composite image appears double. The screen is then in the proper plane. The adjustment is very sensitive and a permanent record can be obtained by replacing the screen by a photographic plate. GEO. GLOCKLER

The detection and estimation of mesothorium in living persons. I. HERMAN SCHLUNDT, HOWARD H. BARKER AND FREDERICK B. FLINN. *Am. J. Roentgenol. and Radium Therapy* 21, 345-54 (1929).—Seven persons who had worked in Ra refineries or luminous-material plants and who might have ingested radioactive material were studied. Electroscope measurements of the  $\gamma$ -ray activity of the subject were made with a Wulf-Hess quartz-fiber instrument. Emanation measurements of the expired air were made with a Lind instrument with a large ionization chamber. Methods for estg. the total radioactive material present, and for discriminating between Ra and MsTh are given. E. H. QUIMBY

Analytical determination of uranium, thorium and lead, as a basis for age-calculations. CLARENCE N. FENNER. *Am. J. Sci.* [v], 16, 369-81 (1928).—Detailed directions are given for the detn. of U, Th and Pb in radioactive minerals such as euxenite, polycrase, samarskite and monazite. B. C. A.

Radioactive minerals from Divino de Ubá, Brazil. C. N. FENNER. *Am. J. Sci.* [v], 16, 382-91 (1928).—A specimen of monazite from Divino de Ubá contained 5.091% Th and 0.0927% Pb, from which its age is calcd. to be  $3.6 \times 10^8$  years. The age of samarskite from the same source is  $3.4 \times 10^8$  years, reckoned from its content of 10.88% U, 1.64% Th and 0.52% Pb. B. C. A.

A basis for dosage determination in interstitial radiation. EDITH H. QUIMBY AND HAYES E. MARTIN. *Am. J. Roentgenol. Radium Therapy* 21, 240-50 (1929).—The distribution of radiation in the tissues around buried radioactive sources, (radon or radium) is detd. for different strengths and arrangements of the sources. Practical dosage problems are considered. E. H. QUIMBY

Pleochroic halos in biotite. D. E. KERR-LAWSON. *Univ. Toronto Studies, Geol. Series* No. 27, 15-27 (1928); cf. C. A. 22, 2106.—An examn. of biotite from Murray Bay, Que., using a microphotometer for detg. the space distribution of the darkening effect in the haloes, indicated that no anomaly with regard to the detd. constants of the uranium series existed. The haloes were exceptionally perfect in definition for their kind, and afford no suggestion that different disintegration const. prevailed during their formation from those now accepted. The persistence of a marked concentric distribution of the darkening effect in the haloes is due to a terminal reversal effect by which in the region of the range of a given set of alpha particles the development of darkening due to other sets of alpha particles is inhibited. J. W. SHIPLEY

The conductivity of metals. LUDWIG KAUL. *Metallbörse* 18, 1435-6 (1928).—A structure is suggested for the Cu atom, composed of H and He atoms so arranged that "electron-channels" exist for the easy passage of electrons. R. J. H.

The perpendicular deflection of slow electrons by gas molecules. RUDOLF KOLATH. *Ann. Physik* 87, 259-84 (1928).—An electron stream, defined by slits, was partly deflected by gas mols. That fraction which was deflected at right angles to the main stream was defined by passing through the spaces between flat ring plates, set perpendicular to and concentric with the main beam. The electrons passing directly through this laminated cylinder and those impinging on the plates were measured by one electrometer, those passing between the plates, which had been deflected perpendicularly, or nearly so, were measured on another. The electron velocities were measured by detg. the opposing field necessary to stop the electron stream. The velocity region 1-6  $\sqrt{v}$ . was studied for He, Ne, A, Kr, H<sub>2</sub>, CO, CO<sub>2</sub>, N<sub>2</sub>O and CH<sub>4</sub>. All these gases showed perpendicular deflection with loss of velocity. Only one max. was found for each gas on the velocity vs. fraction deflected curve. Perpendicular deflection first appears, on reducing voltage, at about 30 v.; the maxima occur in the range 1.5-3.0  $\sqrt{v}$ . The shape and position of the maxima permit division into three groups: A-group, Ne, A, Kr, CH<sub>4</sub>; H<sub>2</sub>-group, H<sub>2</sub>, He; N<sub>2</sub>-CO<sub>2</sub>-group, N<sub>2</sub>, CO<sub>2</sub>, CO, N<sub>2</sub>O. R. L. HERSHEY

Measurement of the heat effects of the condensation of electrons upon metals.

REINHOLD VIOHL. *Ann. Physik* 87, 176-96(1928).—Electrons emitted by a filament were deflected by a magnetic field through slits and on to a Ni block. A Cu-constantan thermocouple was used to measure the heat effects. Corrections were made on the residual kinetic energy from considerations of the magnetic field and the curvature of the electron path. Contact potential may not be neglected. The heat of condensation on Ni is  $97,800 \pm 9800$  cal. per mol.

R. L. HERSHEY

The expulsion of secondary electrons by electrons of 1-30 kilowatts. E. BUCHMANN. *Ann. Physik* 87, 509-35(1928).—The ionization per cm. and at 1 mm. pressure by electrons of velocities above 1 kw. has been measured in air, A, CO<sub>2</sub> and H<sub>2</sub>. The studies for air were carried to 30 kw., for the others to about 7 kw. The electron stream was obtained from a glowing filament, defined by a canal system, passed through an ionization chamber, and received in a Faraday chamber. The ionization current was measured by receiving the pos. ions, rather than the electrons, upon the plate of the ionization chamber. The ionization is proportional to the pressure, and, with the exception of H<sub>2</sub>, equal to a const. times the mol. wt. of the gas. The ionizing power and the probability of ionization decrease with increasing velocity of the primary electrons. No noticeable break in the ionization curve for A was found at the crit. potential of the K shell. The total no. of secondary electrons was detd. at velocities of 4, 7, 8 and 13 kw. The total no. of secondary electrons is directly proportional to the velocity of the primary electrons. The av. energy requirement  $\epsilon$  of secondary electron, in air, is  $31 \pm 3$  v. From the total no. of secondary electrons, the ionization per cm. and  $\epsilon$  the length of path of the primary electrons is calcd. at different velocities. R. L. H.

Electron reflection from cobalt and electron waves. MYRL N. DAVIS. Univ. of Wisconsin. *Nature* 123, 680-1(1929).—The total secondary electron emission from a Co target is measured, and is sep'd. into 2 groups by a retarding potential such that only those electrons having within a few v. of the energy of the primary electrons ( $\epsilon$  e., reflected electrons) can reach the collector. The data show that the important maxima of the total secondary emission may be attributed to the reflected electrons. By applying the Bragg formula, D. calcs. from the most important set of planes for Co in the close-packed hexagonal form the ranges of electron velocities or the bands on the wave-length scale which should be sent back into the receiving cylinder by constructive reflection. By taking their relative intensities as those of the known x-ray reflections, a fair correspondence is obtained between 3 groups of bands and the most prominent maxima of the secondary-electron curve. This necessitated the shifting of the observed curve by about 4 or 5 v., which is about the observed thermionic work function of Co.

G. CALINGAERT

The ratio of ionization and excitation in the motion of electrons through neon. F. M. PENNING AND M. C. TEVES. N. V. Philips Gloeilampenfabrieken, Eindhoven. *Physica* 9, 97-110(1929).—Breakdown of a gas for elec. discharge depends mainly on two factors; the first, how many positive ions are required to liberate one electron from the cathode (C. A. 22, 1904); the second, how many atoms are ionized by an electron in a homogeneous field per unit of distance. The underlying theory is the one of Holst and Oosterhuis (C. A. 18, 786) that at the breakdown point one electron on its way to the anode forms enough positive ions to cause the liberation of one new electron at the cathode. By the method of Townsend with improvements the second problem was exptly. studied on Ne. The problem here studied is different from the one of Compton and Van Voorhis on the probability of ionization; their calcs. include an electron path of only one ionization (cf. also Druyvesteyn, C. A. 23, 760). A curve for  $X/p = \text{const.} = 13.2$  ( $X = v.$  per c. m.;  $p = \text{pressure}$ ) derived from their work has an entirely different shape from those here obtained; it neglects the excitations. Difficulties are met if it is tried to include excitations and thereby calc. the theoretical form of the authors' curves from the data of C. and V.; little is known about the probability of excitation as a function of electron velocity. It is, however, possible to derive from the measurements some values for  $f_i$  the total no. of ionizations performed by an av. electron (one ionization or excitation being taken as max.) on its path and also the ratio of ionizations to excitations  $f_i/(1-f_i)$ . The  $f_i'$  versus  $X/p$  curve for 38.1 v. is a straight line with  $f_i' = 0$  for  $X/p = 4$ ,  $f_i' = 0.22$  for  $X/p = 20$ . The individual detns. derived from the  $f_i$  curves measured show rather considerable deviations; the values for  $f_i$  are taken as preliminary ones. An error of 5 to 10% due to regeneration of electrons by the positive ions is included in the results. For the lower values of  $X/p$  ( $< 15$ ) the curve of  $f_i'$  is considered most reliable. It is also shown that the breakdown potential  $V_d$  rises steeply at the  $X/p$  values where  $f_i$  approaches zero. B. J. C. VAN DER HOEVEN

Selenium and cathode rays. C. E. S. PHILLIPS. *Nature* 123, 681-2(1929).—Careful expts. have shown that the resistance of a Se cell exposed to cathode rays de-

creases rapidly, showing less lag than under exposure to light. X-rays produce a gradual but considerably smaller decrease in resistance.

**Radiometer effect of positive ions.** C. T. KNIPP AND W. S. STEIN. *Phil. Mag.* [7], 7, 70-9(1929).—Expts. are carried out to det. whether pos. ions exert a mech. force on a radiometer or the force is a secondary effect. The evidence, while inconclusive, seems to indicate that a part of the effect is mech.

**Temperatures of positive ions in a uniformly ionized gas.** JANE M. DEWEY. Princeton Univ. *Nature* 123, 681(1929).—An ionized gas may be considered as a mixt. of 3 gases, neutral mols., electrons and pos. ions, each occupying a different energy level, *i. e.*, having a different temp. Assuming (1) that the pos. ions acquire energy solely from the energy of random motion of the electrons, and (2) that they lose energy by collision with the mols. of neutral He at a rate which may be calcd. from the kinetic theory, D. calcs. the temp. of the pos. ions from that of the electrons and the pressure of the gas in a field-free space. The results are compared with those observed by D for He (C. A. 23, 2654). The calcd. values, although consistently high, agree in order of magnitude, and are within the error of calcn. and measurement. According to the calcn. the ion temp. should increase with decreasing electron temp. and increase with increasing electron concn.

**Photoelectric emission from phototropic mercury compounds.** BH. S. V. RAGHAVA RAO AND H. E. WATSON. *J. Indian Inst. Sci.* 12A, 17-29(1929); cf. C. A. 22, 4382.—By making use of a thermionic valve in conjunction with a photoelec. cell, the photoelec. emission from 12 phototropic Hg compds. of the type  $Hg.X_2$ ,  $2Hg.Y$  and  $X.Hg.CNY$  was measured ( $X = Cl, Br, I, HS, CNS, CNSe$ ;  $Y = O, S, Se$ ). A quartz-Hg arc lamp was the source. In all cases the emission from compds. prepd. in the dark was either zero or very small. On exposure to light the compds. darkened and the emission increased to a max. and then remained steady. In a few instances increase in emission took place in 2 stages, indicating the formation of an intermediate compd. The initial photoelec. current depends somewhat on the duration of exposure of the compd. to light; but the final max. did not deviate in value over a period of 80 hrs. On heating or keeping in the dark, the photosensitiveness decreased to that of the freshly prepd. compds. The max. current for any compd. was  $82 \times 10^{-11}$  amps. and the lowest was  $1.5 \times 10^{-11}$  amps. No definite relation could be found between phototropic and photoelec. activity.

**The magnetic moment of the complex ions of the iron group.** PIERRE WEISS. *Trans. Am. Electrochem. Soc.* 55, (preprint) 4 pp.(1929).—The magnetic moments of the simple ions of the Fe group, with minor exceptions, depend only on the no. of electrons in the ion, in accordance with Kossel's displacement law, and as shown by Cabrera's curve. For complex ions an "effective" atomic no.,  $N^1$ , must be used, which is defined by the equation  $N^1 = N - v + 2i - 2p$ , in which  $N$  is the total number of electrons in the central atom,  $v$  the valence,  $i$  the coordination index, and  $p$  the no. of pairs of electrons in the outer shell;  $p$  is generally 4 (rare-gas configuration), but in some cases the influence of the subjacent  $M$  shell may cause  $p$  to become 6, in which cases the coordination index will be 6 also. This leads to a generalization of Kossel's law: "The magnetic moment of a complex ion is equal to that of the normal ion of the same valence or to that of a normal ion whose effective at. no. is greater by 4." B. MILLER

**The longitudinal magnetic action upon bundles of slow electrons (concentrations and periodic expansion).** JEAN THIBAUD. *Compt. rend.* 188, 54-6(1929).—A theory based on classical considerations is developed for the periodic distention of slow-electron beams (under 500 v.) produced by a magnetic field.

**Cathode drop.** M. E. BĂDĂRĂU. *Bul. stiinte fizice soc. română stiinte* 29, 3-8 (1926-7).—Two theories have been advanced to explain the phenomenon of cathode drop. The Starck theory assumes the existence of an ionization potential of metals by positive ions. The Holm theory assumes that metals struck by positive ions emit electrons, whatever may be the energy of these ions. It follows from the latter that the cathode drop is due to the necessity of equil. between the ions which strike the cathode and the ions derived from gaseous mols., ionized by electrons emitted by the cathode. Tests to verify one or the other assumption have shown that the Starck theory must be abandoned, while that of Holm can serve as a starting point. E. M. S.

**Continuous spectrum x-rays from thin targets.** WARREN W. NICHOLAS. *Bur. Standards J. Research* 2, 837-70(1929).—The continuous radiation from thin Al and Au foils as anticathodes in x-ray tubes is analyzed by a crystal. The high-frequency limit of the continuous spectrum from an infinitely thin target consists of a finite discontinuity. The energy distributions on a frequency scale are approx. horizontal for Al and for Au and for  $\psi = 40^\circ, 90^\circ$  and  $140^\circ$ , where  $\psi$  = angle between

measured x-rays and cathode stream; this agrees with Kramer's, but not with Wentzel's theory. The intensities for these values of  $\psi$  are 3:2:1, resp. Observations do not support a supposed quantum process in which a single cathode ray, losing energy  $h\nu$  by interaction with a nucleus, radiates a single frequency,  $\nu$ , in the continuous spectrum, nor the "absorption" process assumed by Lenard. The synthesis of thick-target spectra from thin targets is discussed and empirical laws are formulated describing the dependence on  $\psi$  of thick-target continuous spectrum energy. A structure for the moving electron is proposed.

H. W. WALKER

**The complexity of the  $K\beta'$  line of x-ray spectra.** V. DOLEJŠEK AND H. FILČÁKOVÁ. *Nature* 123, 412-3(1929).—Earlier investigations appeared to show that the  $K\beta'$  line seemed to be distinguished only with certain compds. but D. and F. now show on various Mn compds. that such is not the case. In all cases studied the  $K\beta'$  line is readily distinguished. The line is studied for various elements and found to be a complex line and it is impossible to arrange it in the scheme of Bohr and Coster. The origin of the line is as yet unknown.

GEORGE GLOCKLER

**Determination of total absorption coefficients of different metals and organic compounds in the short wave-length x-ray region.** H. STUMPEN. *Z. Physik* 50, 215-27(1928).—The total absorption coeffs. for Cu, Ag, Al,  $H_2O$ , toluene, xylene, olein and stearic and palmitic acids have been detd. with radiation from Cu, Ag, Mo and W anticathodes. The wave-length range was from 0.1 to 0.7 Å. U. A Bragg spectrometer, with a calcite crystal, was used to obtain a monochromatic beam. Two opposed ionization chambers, only one of which was exposed to the x-radiation, were used. The second compensated the losses due to ionization of the air, which, because of the highly sensitive electrometer used, were not negligible. The results are presented in tables and photographs. The results for metals agree well with those of Allen and Richtmyer.

R. L. HERSHEY

**Diffraction of x-rays in liquids containing heavy atoms.** J. A. PRINS. *Nature* 123, 84(1929).—By means of the spectrograph devised by Coster and P. (C. A. 22, 4292) the diffraction patterns caused by heavy atoms in a soln. have been studied, the solvent being a liquid having such light atoms that diffraction from it may be neglected. Solns. of I ions in  $H_2O$ , and  $CCl_4$  and methylene iodide in  $C_6H_6$  were used. If the dissolved mols. are dispersed like mols. in the gaseous state the scattering at small angles should be greater than that for ordinary liquids. Such an effect was found for d<sup>1</sup> solns. For concd. solns. of I ions (KI and LiI) a reversal is found, scattering again decreasing with increasing concn. This cannot be explained by a geometrical close-packing, but may be due to electrostatic repulsion, as if the ions were much larger, causing an apparent close packing.

R. L. HERSHEY

**Method of determining the orientation of crystal axes by x-rays.** S. TAKEYAMA. Kyoto Imp. Univ. *Mem. Coll. Sci. Kyoto Imp. Univ.* 11A, 469-79(1928).—A V-shaped frame of Pb wires is placed on an ordinary rotating crystal spectrometer between the crystal and the plate and rotated with the crystal. The defining system is a long vertical slit producing vertical lines on the photographic plate. The positions of the shadows cast on these lines by the Pb wires, together with the knowledge of the diffracted wave length, permit the calcn. of the crystallographic axial orientation. The method is useful for thick crystals, for substances on the surface of thick materials and for microcrystals on metallic surfaces. Microcrystals on the polished surface of Cu have their (111) or (100) planes nearly parallel to the polished surface.

R. L. HERSHEY

**The intensities of x-ray diagrams of native cellulose.** K. R. ANDRESS. *Z. physik. Chem.*, Abt. B, 2, 380-94(1929).—An interpretation of the intensities of x-ray diagrams is given.

H. W. WALKER

**The fine structure of the normal scattered molybdenum  $K\alpha$  radiation from graphite.** D. COSTER, I. NITTA AND W. J. THIJSEN. Rijks Univ., Groningen. *Nature* 123, 442(1929).—The work of the authors confirms that of Ehrenberg (C. A. 23, 2360) disproving the contention of Davis and Mitchell (C. A. 23, 765) that the normal scattered radiation from x-rays should have a much more complicated structure than the primary radiation.

G. CALINGAERT

**Remark on the fine structure of the Compton effect.** MAURICE DE BROGLIE. *Compt. rend.* 187, 697(1928).—The results of Davis and Mitchell (C. A. 23, 765) lead to the conclusion that the continuous x-ray spectrum, diffused under the influence of an exciting pencil contg. all wave lengths, must show bands and in the curve of total absorption of an element vs. wave length a part of the absorption max. must be attributed to diffusion.

ALBERT L. HENNE

**Contributions to the method of crystal class determination.** A. HETTICH AND A. SCHLEERDE. *Z. Physik* 50, 249-65(1928).—X-ray examn. of crystals permits the

differentiation into only 11 of the 32 classes, i. e., into those having symmetry centers. This is due to the fact that the x-ray diffraction introduces an apparent symmetry center, whether such exists in the crystal or not. Further differentiation must depend upon some method of polarity study. H. and S. have used the high-frequency piezoelec. method of Giebe and Scheibe (*C. A.* 23, 3207) to investigate a no. of crystals, all systems being represented. The 11 crystal classes having symmetry centers naturally do not produce any effect. Thus it is possible to decide on the presence of a symmetry center. The static method of Meissner (*C. A.* 21, 3825) has been used on  $\text{NaClO}_3$ , cane sugar and tartaric acid. It is possible to explore a no. of crystallographic directions from a single point on the crystal. A diagrammatic representation of the polarity characteristics of each of the 32 classes is included. The expts. agree with this representation. Laue diagrams and a detn. of the polarity characteristics by Meissner's method permit a unique detn. of the crystal class.

R. L. HERSHEY

The angular distribution of Compton recoil electrons. D. SKOBEŁTYN. *Nature* 123, 411-2(1929).—Up to the present the intensity problem of the Compton effect has been left unsolved. There are 2 ways of exptl. test: the investigation of angular distribution of secondary quanta (scattered) radiation and the study of secondary electrons. In both cases decisive information may be obtained only by using  $\gamma$ -rays. The angular distribution of 1000  $\beta$ -ray tracks from a narrow beam of  $\gamma$ -rays filtered through 3.5 mm. of Pb has been detd. and is compared with theory. The angular distribution is definitely not in accord with the theory of Dirac (*C. A.* 21, 2599) and that of Gordon (*C. A.* 3542) but the formula of Klein-Nishina (*Z. Physik* 52, 853-68(1929)) is in good agreement with the present data. The discrepancies, however, exceed even in this case the probable statistical deviations.

GEORGE GLOCKLER

The Raman and infra-red spectra of carbon dioxide. C. R. BAILEY. *Nature* 123, 410(1929).—The results of Rasetti (*Nature* 123, 205(1929)) on the Raman lines in  $\text{CO}_2$  lead B. to consider the emission spectrum of  $\text{CO}_2$  in the infra-red (*C. A.* 22, 2887) as a system of bands which are themselves multiples of a fundamental frequency  $\nu_0 = 107 \text{ cm}^{-1}$ . The wave nos. of the individual bands are obtained by multiplying by  $N$  ( $N$  ranges from 12 to 64). At present it is difficult to see the underlying phys. significance of the results.

GEORGE GLOCKLER

A violation of the selection principle for the principal quantum number. SAKAE IDER. *Phys. Lab. Upsala, Sweden. Nature* 123, 643(1929); cf. Thibaud, *C. A.* 22, 3808.—Careful measurements in the L series and detn. of  $\nu/R$  for the 2 new lines of Ta, W, Pt and Au seem to indicate that the doublets found by Thibaud and Soltan (*C. A.* 22, 1098, 2713) are due to the transitions  $N_{IV}-N_{VI}$  and  $N_V-N_{VI,VII}$ . This would then be the first exptl. evidence of x-rays transitions within the levels of the same principal quantum nos.

G. CALINGAERT

Fine structure absorption edges in metals. B. B. RAY AND P. C. MAHANTI. *Nature* 123, 528-9(1929).—It is well known that when pure metals are examd. by x-ray absorption in general no fine structure edges are observed. If the fine structure edge is supposed to be due to the removal of an electron from the K shell to the various optical levels of the atom, then the non-appearance of the fine structure in metals can be explained by assuming that electrons in metals are free and there exist no definite optical levels in the atoms in the metallic state.

GEORGE GLOCKLER

Origin of the ultra-violet beryllium hydride band spectrum. E. BENGTSSON. *Nature* 123, 529(1929).—The carrier of the ultra-violet BeH band spectrum is shown to be the  $\text{BeH}^+$  mol. (cf. Watson, *C. A.* 23, 768).

GEORGE GLOCKLER

Spectral absorption of certain monoazo dyes. I. The effect of position isomerism on the spectral absorption of methyl derivatives of benzeneazophenol. WALLACE R. BRODE. U. S. Bur. Standards. *Bur. Standards J. Research* 2, 501-40(1929).—Azobenzene, benzeneazophenol, and all the possible mono- and di-Me derivs. of  $\text{PhN}_2\text{C}_6\text{H}_4\text{OH}$ , in which not more than 1 Me substitution occurs in a  $\text{C}_6\text{H}_5$  ring, have been prepd. and their absorption spectra studied, in EtOH, concd. HCl and 3% aq. NaOH as solvents. Similar effects to those observed on these dyes in NaOH as a solvent (*C. A.* 23, 2428) are shown in the alc. and HCl solns. in particular the  $p'$ -substitution increasing the absorption and the  $o'$ -substitution decreasing the absorption. A simple mathematical relation is shown to exist between the frequencies of the absorption bands observed in any one solvent. A more extended discussion of the component bands in NaOH is given.

WALLACE R. BRODE

Relations between the absorption spectrum and chemical constitution of azo dyes. II. Influence of position isomerism on the absorption spectrum of the nitro derivatives of benzeneazophenol, benzeneazo-*o*-cresol and benzeneazo-*m*-cresol. WALLACE R. BRODE. *Ber.* 61B, 1722-31(1928); cf. preceding abstract.—The absorp-

tion spectra of alc. solns. and of solns. in aq. NaOH of the nitro derivs. of benzeneazo-phenol, benzeneazo-*o*-cresol and benzeneazo-*m*-cresol were measured from the red to the ultra-violet (frequency interval from 400f to 1300f). The results, illustrated graphically show that the principal band of the *o*'- and *m*'-nitro derivs. of benzeneazo-phenol is accompanied by a second band of higher frequency; and that the principal band of these compds. in aq. NaOH appears to be double. A comparison of these results with those previously obtained for the Me derivs. (C. A. 23, 2428) shows that a shift of the bands to lower frequencies accompanies an increase in mol. wt. of the dye; that a marked increase in intensity of the principal band and a slight intensity decrease in the second band is effected by substitution of a nitro group in the *p*'-position, that substitution of the nitro group in the *o*'-position brings about a general decrease in intensity of the absorption without altering the positions of the bands. C. C. KIRSS

Near infra-red absorption spectra of some aldehydes, ketones, esters and ethers. JOSEPH W. ELLIS. Univ. of Calif. *J. Am. Chem. Soc.* 51, 1384-94 (1929).—The near infra-red absorption spectra (below  $2.5\mu$ ) have been recorded for a no. of aldehydes, ketones, esters and ethers. The observed absorption band (often doubled) between  $1.9$  and  $2.0\mu$  in all the carbonyl compds. studied is interpreted as the second overtone of the  $5.8\mu$  band which has been previously ascribed to the carbonyl group. There is evidence in some compds. for the third, fourth and fifth overtones of the  $5.8\mu$  band at  $1.45$ ,  $1.61$  and  $0.97\mu$ , resp. WALLACE R. BRODE

The line absorption of chrome alum crystals. H. SAUER. *Ann. Physik* 87, 197-237 (1928).—The line absorption of chrome alums of the type  $\text{RCr}(\text{SO}_4)_2 \cdot 12\text{H}_2\text{O}$  with K, Rb, Cs, Tl,  $(\text{NH}_4)$ ,  $(\text{NH}_4\text{OH})$  and  $(\text{NH}_4\text{CH}_3)$  as the univalent cation and of the type  $\text{RCr}(\text{SeO}_4)_2 \cdot 12\text{H}_2\text{O}$  with K, Rb, Tl and  $(\text{NH}_4)$  as cations has been measured at  $-190^\circ$ ,  $-78^\circ$  and  $+18^\circ$ , as has the continuous absorption of the K Cr alums at room temp. The wave-length range was from about 6200 to 6800 Å. U. The effects of different cations and of the substitution of  $(\text{SeO}_4)^{--}$  for  $(\text{SO}_4)^{--}$  are in general found in position and intensity changes of the absorption lines, with a const. characteristic appearance, so that the individual lines of the various alums may be related. CsCr and  $(\text{NH}_4\text{CH}_3)$  Cr alums are an exception; their lines correspond for themselves but not for the other alums, an effect probably due to lattice change. In the shorter wave-length range a regular equidistant line series is found, which may be explained as due to coincidence of lattice, electron and perhaps mol. vibrations, and which corresponds to a residual ray wave length of  $232\mu$ . Increasing temp. displaces the lines and continuous absorption toward longer wave lengths. The lines broaden proportionally to  $\sqrt{T}$ . A characteristic and intense doublet appears in most alums at about 6700 Å. U. The ratio of absorbing to total centers is  $3 \times 10^{-8}$  for the characteristic doublet; for the continuous absorption in the visible ultra-violet it has a max. of about  $10^{-3}$ . A not electrostatically bound, hompolar Cr- $(\text{H}_2\text{O})$  complex appears as the probable unit in causing the line absorption. R. L. HERSHEY

Line absorption spectra in solids at low temperatures in the visible and ultra-violet regions of the spectrum. S. FREED AND F. H. SPEDDING. *Nature* 123, 525-6 (1929).—Hund calcd. (C. A. 20, 144) the character of the most stable energy level of certain rare gas ions and their corresponding magnetic moments, assuming a certain arrangement of electron levels and the presence of the normal multiples coupling between the orbital and spin moments of the electrons. He assumed that the rare-gas ion was in the gaseous state and found beautiful agreement with magnetic data on the solids and their solns. This remarkable fact suggested to F. and S. that the absorption spectra of the rare earths might resemble the line spectrum of their ions in the gaseous state. They studied  $\text{GdCl}_3 \cdot 6\text{H}_2\text{O}$ ,  $\text{SmCl}_3 \cdot 6\text{H}_2\text{O}$  and  $\text{ErCl}_3 \cdot 6\text{H}_2\text{O}$  at various temp. down to liquid  $\text{H}_2$  temp. and found that the absorption spectra were made up of lines which became finer at lower temps. This work promises quant. information concerning the influences of neg. ions and water of crystn. on the various spectra. G. G.

The influence of adsorbed ions on the light absorption of heavy-metal halides. K. FAJANS AND G. KARAGUNIS. Chem. Lab. Bayer Akad. Wissenschaften, München. *Naturwissenschaften* 17, 274 (1929).—Previously extinction measurements on the light absorption by AgBr showed an influence of adsorbed Ag and Tl ions (cf. Fromherz, C. A. 22, 4381; C. A. 23, 3176). The influence of gelatin was negligible; similar effects were found for  $\text{PbI}_2$  in the presence of Pb ions, i. e., there is always an increase in extinction. These measurements were all made in the long-wave range but expts. were now performed with finely dispersed AgI (little scattering of light) on both sides of a max. of the absorption curve at  $420m\mu$ .  $\text{Ag}^+$  adsorbed on AgI causes an increase in absorption at all points up to 40%, 0.05 N  $\text{AgClO}_4$  being used. It is assumed that the light absorption is closely related to the photoelec. cond. and to the photochem. decompn.

of AgI. The adsorption complex  $(Ag_2I_2)Ag^+$  may be considered as an intermediary step in the soln. process of AgI in Ag salt solns. whereby complex ions,  $Ag_2I^+$ , are formed. The intermediary substance absorbs strongly; the end product,  $Ag_2I^+$ , however, absorbs practically no visible light, having a first absorption max. at  $245.5m\mu$  in the ultra-violet (Fromherz and Menschick, cf. following abstr.). Apparently a loosening up of the AgI lattice takes place first with considerable deformation of the I shell and increased absorptive ability; later a closing of the electron shield of I constitutes the second phase of the soln. and assocn. process.

B. J. C. VAN DER HOEVEN

Optical relations between alkali halide phosphors and complex salt solutions. H. FROMHERZ AND W. MENSCHICK. Chem. Lab. Bayer Akad. Wissenschaften, München. *Naturwissenschaften* 17, 274-5(1929).—Alkali halide phosphors are formed by the incorporation of traces of heavy metal ions (Ag, Cu, Pb, Tl) in the lattice of alkali halide crystals. For the excitation absorption bands in the ultra-violet are necessary which closely resemble those of the pure admixt. but are of a peculiar sharpness (cf. Pohl, C. A. 22, 3356, 4371), for which a special chem. condition is suggested to be responsible. If this condition consists of the coöperation of a strongly deformed cation (heavy metal, not an inert gas-like one) with a deformable anion (halide) an analog of this condition is found in concd. solns. of heavy-metal halides with alkali metal halides. With the solns. the result of the interaction will be the assocn. to complex ions ( $AgCl_2^-$ ,  $CuCl_3^{--}$ , etc.). The absorption spectra of these complex ions were therefore compared with those of the alkali halide phosphors investigated by Smakula (C. A. 22, 193) and by MacMahon (C. A. 23, 766). For the solns. the extinction curve by the pure alkali halide was graphically subtracted from the total one to give that of the complex only. It was found that in shape, position and sharpness the bands of both systems agree; those of the solns. are shifted 6 to  $10m\mu$  towards the red (pure alkali halide solns. show a  $30m\mu$  red shift as compared with their spectrum in cryst. form). From the ratio of intensities of absorption it is derived that only 0.2 to 2% of the heavy metal in the crystal lattice is optically active. The curves given are of NaCl + 0.6% Ag and of KCl + 1.0% Cu in crystal form; the corresponding ones in intensity are of solns. of NaCl + AgCl ( $c = 1.41 \times 10^{-3}$  mol. per l.) and KCl + CuCl ( $c = 1.95 \times 10^{-3}$  mol. per l.).

B. J. C. v. d. H.

Color and optical anisotropy of organic compounds. C. V. RAMAN. *Nature* 123, 494(1929).—From the study of scattering of light done at Calcutta R. deduces the following generalization: The types of mol. structure of Ca compds. which favor the development of color are those which exhibit an exceptionally high degree of optical anisotropy.

GEORGE GLOCKLER

Hyperfine structure in the arc spectrum of cesium and nuclear rotation. D. A. JACKSON. *Proc. Roy. Soc. (London)* A121, 432-47(1928).—The arc spectrum of Cs was investigated to det. if any of its lines possessed hyperfine structure, resulting from a nuclear magnetic moment, due to quantized nuclear spin. The lines belonging to the principal series would, because of the greater degree of penetration of the electron in the  $1s$  or  $6i$  orbit, and the correspondingly greater interaction, show the greatest effect. The lines of the principal series are very easily broadened if the vapor pressure of the metal becomes high, so that great care had to be used in obtaining the spectrum of Cs at a sufficiently low temp. The most satisfactory method of excitation was the application by means of external electrodes of a very high-frequency a. c. to a tube of Heat about 2-mm. Hg pressure contg. a small quantity of Cs. The lines belonging to the principal series were very close doublets with very nearly const. frequency differences. The measurements were made from spectrograms obtained with grating or prismatic spectrographs in conjunction with Fabry and Perot interferometers with 2.5-5-, 10- or 20-mm. etalons. The frequency differences in  $cm^{-1}$  for the 6 lines constituting the first 3 pairs of the principal series are  $0.315 \pm 0.003$  for  $1S - 2^2P_{1/2}$ ,  $0.294 \pm 0.001$  for  $1S - 2^2P_{3/2}$ ,  $0.308 \pm 0.003$  for  $1S - 3^2P_{1/2}$ ,  $0.300 \pm 0.003$  for  $1S - 3^2P_{3/2}$ ,  $0.305 \pm 0.010$  for  $1S - 4^2P_{1/2}$  and  $0.299 \pm 0.005$  for  $1S - 4^2P_{3/2}$ . A theory is worked out which explains the origin of these doublets, assuming a nuclear spin of one-half quantum; by correlating the difference in sepn. of the hyperfine structure doublets in the  $1S - m^2P_{1/2}$  lines and the  $1S - m^2P_{3/2}$  lines, it is shown that a ratio of the magnetic to the mech. moment of the nucleus about twice as great as the corresponding ratio for the electron would account for the observed frequency differences. The results are compared with those found for the hyperfine structure of some of the Bi lines by Back and Goudsmit, and are found to be in satisfactory agreement. A selection principle is found which applies to the Bi and the Cs spectrum.

W. F. MEGGERS

The arc spectrum of samarium. Measurements made at normal pressure between  $\lambda = 2750$  A. U. and  $\lambda = 2200$  A. U. S. PIÑA DE RUBIES. *Compt. rend.* 188, 1101-2(1929).—The list of new lines published for Sm (cf. C. A. 23, 2654) is extended

in the ultra-violet. The wave lengths of about 150 faint new lines range from 2748.73 to 2284.98 A. U. W. F. MEGGERS

The intensities of some  $\text{Fe}^+$  multiplets in the arc and chromosphere spectra. WM. CLARKSON. *Phil. Mag.* [7], 7, 98–105 (1929).—Results of intensity measurements of the multiplets  $2^4\text{F} - 2^4\text{F}'$  and  $2^4\text{F} - 2^4\text{D}$  for ionized Fe, for an Fe arc, and for the chromosphere ("flash" spectrum) show similar wide divergencies from theoretical intensities of individual lines. One line in each multiplet is particularly abnormal. Comparisons of multiplet summations show (1) the multiplet summation rules apply in the case of ionized Fe, as in Ni and Co, only when extended to the total sums of the 2 multiplets; (2) the arc is free from self-absorption and thus gives fundamental line intensities, while the flash sums demonstrate self-absorption. The flash arc relation was found to be linear but the 2 very abnormal lines lie off this curve. L. H. REYERSON

An analysis of the arc and spark spectra of yttrium (Yt I and Yt II). WM. F. MEGGERS AND HENRY N. RUSSELL. *Bur. Standards J. Research* 2, 733–69 (1929).—This paper presents an almost complete classification of the spectra emitted by the neutral and singly ionized atoms of Yt, and a partial classification of lines emitted by the doubly ionized atom. In Yt III the term  $4^2\text{D}$ ,  $5^2\text{S}$ ,  $5^2\text{P}$ ,  $6^2\text{S}$ ,  $5^2\text{D}$  and  $4^2\text{F}$  have been found. The terms of Yt II belong to the singlet and triplet systems,  $1\text{S}_0$  coming from  $s^1$ , being lowest. In Yt I the terms belong to the doublet and quartet systems, with  $1\text{D}$ , coming from the electron configuration  $(5s)^24d$ , lowest. The identifications of many of the terms have been established by Zeeman effects. In all 3 spectra terms which form series have been found, and from these the following ionization potentials have been calcd.: 6.5 v. for the neutral atom; 12.3 v. for  $\text{Yt}^+$ ; and 20.6 v. for  $\text{Yt}^{++}$ . In all, 448 lines of Yt I, 223 of Yt II, and 10 of Yt III have been classified. C. C. K.

The arc spectrum of silicon. A. FOWLER. Imperial Coll. of Science and Technology, London. *Proc. Roy. Soc. (London)* A123, 422–39 (1929).—New wave lengths of Si I have been obtained with a vacuum grating spectrograph down to 1600 A. U. in the Schumann region. These, together with those of longer wave length previously detd., were made the basis of an analysis of the term structure of the arc spectrum. The deepest term is  $3^2\text{P}$  coming from the configuration  $s^2p^2$ . The other terms which have been found are triplets and singlets and are in accord with those required by Hund's theory. Several series of terms have been established from which the value  $65765 \text{ cm.}^{-1}$  is derived for  $3^2\text{P}_0$ . This gives an ionization potential of 8.12 v. for the neutral Si atom. A comparison of the structure of Si I with P II shows a close similarity between the two. Comprehensive tables contain the details of the investigation. C. C. KIESS

The spectrum of doubly ionized nitrogen (N III). L. J. FREEMAN. *Proc. Roy. Soc. (London)* A121, 318–43 (1928).—The spectrum of doubly ionized N has been photographed from 8000 to 850 A. U. by using condensed discharges in vacuum tubes contg. N. The lines of N III have been distinguished from those of other stages of ionization by comparing the relative intensities of the lines under various conditions of discharge. The wave lengths corresponding to 154 lines have been measured; they range from 979.9 A. U. to 6487.55 A. U. Most of these lines have been classified, 100 in the quartet system and 20 in the doublet system. No intercombinations between doublet and quartet terms have been found but approx. values for the deepest term of each were derived from successive terms fitting a Rydberg formula. Thus the abs. values for the ground term  $3^2\text{P}_{1,2}$  are 384088.4 and 383914.0, while the lowest quartet level identified is about 163078.3 which should be increased by about 58,000 to bring it to the same zero as the doublet term. The lowest of the quartet terms has not yet been evaluated; by analogy with the doublet terms, it seems probable that it should lie near 380,000. W. F. MEGGERS

A preliminary report on the measurement of the  $\text{K}_\alpha$  line of carbon. CARL E. HOWE. *Proc. Natl. Acad. Sci.* 15, 251–3 (1929).—The wave length of the  $\text{K}_\alpha$  line of C has been measured by others; the values range from 44.9 A. U. to 45.5 A. U. New measurements are now made from spectrograms made at grazing incidence from a ruled grating in a vacuum spectrograph. The mean of 14 detns. is  $44.60 \pm 0.04$  A. U. W. F. MEGGERS

Separation of various spark spectra of antimony. R. SOULILLOU. *Compt. rend.* 188, 1103–4 (1929).—The electrodeless discharge which with a large no. of elements has been found useful in identifying groups of lines belonging to successive stages of ionization is employed for a similar purpose with Sb. Between 3800 and 1900 A. U. nearly 300 lines have been recorded and these are divided among Sb II, Sb III and Sb IV spectra. The wave lengths for 40 lines (3719.60 to 2054.01 A. U.) of Sb II, 17 lines (3738.58 to 2479.17 A. U.) of Sb III, and 19 lines (3687.01 to 2076.37 A. U.) of Sb III are presented. W. F. MEGGERS

**The continuous spectrum of the hydrogen tube.** D. CHALONGE AND M. LAMBREY. *Compt. rend.* 188, 1104-6(1929).—Investigation of the continuous spectrum from H between 2200 and 4500 A. U. shows that (1) as the pressure increases the intensity of the continuous spectrum passes through a max. between 2 and 3 mm.; (2) for a given pressure the intensity increases with current but the distribution is not sensibly modified by change in current; (3) the spectral distribution of energy emitted by tubes of different designs differs extremely little; (4) the intensity as compared with that of a C arc is about 2.1 at  $\lambda 4400$  and 23.0 at  $\lambda 2200$ . These features suggest the possible use of radiating H tubes as intensity standards in the ultra-violet. W. F. MEGGERS

**The structure of the band spectrum of helium.** V. W. E. CURTIS AND A. HARVEY. *Proc. Roy. Soc. (London)* A121, 381-401(1928); cf. C. A. 22, 1910.—The details and analysis of 5 new  $\text{He}_2$  bands are given. One of these is a weak vibrational band assoc. with the known band near 5730 A. U. ( $3D \rightarrow 2P$  of  $\text{He}_2$ ). Another is the  $\text{He}_2$  counterpart of the  $\text{He}$  band designated  $3X \rightarrow {}^3P$ . The remaining 3 have  ${}^3P$  as the final electronic level and a new type of level (Z) as initial. It is rotationally single like S and X but the rotation terms cannot be represented by the usual type of formula, nor are the relative intensities of the branches at all similar to those in other bands. In consequence of the abnormal character of the initial level the appearance of the Z - P bands is very peculiar; the wave nos. of the R branch, e. g., decrease continuously with increase of rotational quantum no., thus giving it the appearance of a P branch. Two perturbations are recorded in these bands, one a large displacement and the other a splitting into 2 components of about equal intensity. The Zeeman effect has already been found to be very unusual in magnitude and character for the  $4Z \rightarrow 2P$  band. The X and Z levels are clearly addnl. to the ordinary at. system of levels, and evidence is discussed which leads to a tentative identification of them with certain new types predicted by Hund for diatomic mols. but not hitherto definitely established by observation. Although the chief properties of the new bands may readily be accounted for on this view, several unexplained peculiarities remain, such as the absence of Q branches in  $X \rightarrow P$  transitions and the relative intensities of the branches in Z - P transitions. W. F. MEGGERS

**A study of the helium band spectrum.** SUNAO IMANISHI. *Sci. Papers Inst. Phys. Chem. Research (Tokyo)* 10, 193-209(1929).—Improvements in the technic of producing the band spectrum of  $\text{He}_2$  have made it possible to obtain good spectrograms for the region 3000 A. U. to 7000 A. U. in the first 4 orders of a 15-foot concave grating with exposures of 4 to 10 hrs. Some of the results for bands between 3180 A. U. and 3570 A. U. are given. Three new bands at 3356, 3367 and 3564 A. U. are found, and extensions are made to other series. W. F. MEGGERS

**The Fulcher bands of hydrogen.** IAN SANDERMAN. *Proc. Roy. Soc. Edinburgh* 49, 48-64(1929).—The band spectrum of  $\text{H}_2$  presents a problem of peculiar interest since our knowledge of mol. spectra cannot be said to be satisfactory until the spectrum emitted by the mol. of the lightest element has been elucidated. The first advance was made in 1913 when Fulcher discovered the 2 triplet and 4 singlet series commonly called the "Fulcher bands" interpreted as due to changes in rotational energy of the emitting mol. The Fulcher triplets are the first 3 members of series spaced according to a parabolic law, and the hypothesis has been advanced that these series are due to rotational changes in the mol. while the spacing of the triplets themselves was traceable to changes in vibrational energy. This hypothesis recently received striking confirmation in the work of Richardson (C. A. 20, 2949, 21, 705), who has shown the existence of the complete band analog of the Balmer series in the secondary spectrum of H. However, the new and more accurate measurements by Gale, Monk and Lee, while strongly confirming Richardson's allocation of the Q branches, have failed to yield confirmation of the remaining branches which he gives. The present paper gives a no. of combination relations which have been found to hold between the lines of the Fulcher bands. These indicate that there are 3 main branches in each band, designated R', Q, and P' branches, the Q branch being identical with that of Richardson. The R' and P' branches have a common initial level differing from that of the Q branch, while all 3 branches have a common final level. W. F. MEGGERS

**The Fulcher bands of hydrogen.** IAN SANDEMAN. *Nature* 123, 410-11(1929) — S. inquires how the Fulcher bands of  $\text{H}_2$  fit into the new wave mechanics and in particular detcs. the const.  $\sigma$  in the term form  $B(j(j+1) - \sigma^2)$ . An analysis of the bands shows that the terms fit this form provided the quantum no.  $j$  is given integral values. The further consequences of this relation are discussed in terms of modern band analysis. GEO. GLOCKLER

**The band spectrum of fluorine.** H. G. GALE AND G. S. MONK. *Astrophys. J.*

69, 77–102(1929); cf. *C. A.* 22, 4062.—The principal bands of  $F_2$  are photographed with a grating of large dispersion (2.63 Å./mm.); the new measurements show that the bands consist of *P*, *Q* and *R* branches with alternate weak and strong lines in each branch. The *Q* branch is about twice as strong as the *P* and *R* branches. Two of the strongest bands, whose null points lie at  $\nu_0 = 16378.8$  and  $\nu_0 = 17439.5$ , have been completely analyzed, and three fainter bands at  $\nu_0 = 15337.6$ ,  $\nu_0 = 17075.9$  and  $\nu_0 = 18548.4$  partly analyzed. There are strong perturbations in all the bands in both frequency and intensity which have hitherto masked their true character. These perturbations are in the initial state. The analysis of the bands yields the following values of the moments of inertia for the initial and final states of the  $F_2$  mol. and the internuclear distances, resp.,  $I'_0 = 34.2 \times 10^{-40}$ ,  $I_0'' = 26.0 \times 10^{-40}$ ,  $\gamma'_0 = 1.48 \times 10^{-8}$  cm.,  $\gamma_0'' = 1.28 \times 10^{-8}$  cm. The structure and intensity relations indicate that the bands are of the  $^1S - ^1P$  type. A ratio of intensities of strong to weak lines within a branch of 3:1 indicates a nuclear spin of  $1/2(h/2\pi)$ ; the best plots show this intensity ratio to be at least 3:1 and probably greater (cf. *C. A.* 22, 4062). W. F. MCGEES

The spectrum of hydrogen. The bands analogous to the parhelium line spectrum. II. O. W. RICHARDSON AND P. M. DAVIDSON. King's College, London. *Proc. Roy. Soc. (London)* A123, 466–88(1929); cf. *C. A.* 23, 2096.—Details are presented of a third system of  $H_2$  bands which originate in the electronic levels with principal quantum no. 3, the other 2 systems having been previously described (*C. A.* 23, 2883). These new bands are designated as the  $3^1A \rightarrow 2^1S$  system and are characterized by strong *P* branches, weak *R* branches, and the absence of *Q* branches. The lines show no Zeeman effect. Coming from the electronic levels with principal quantum no. 4 are 5 band systems denoted by  $4^1A \rightarrow 2^1S$ ,  $4^1B \rightarrow 2^1S$ ,  $4^1C \rightarrow 2^1S$ ,  $4^1X \rightarrow 2^1S$ , and  $4^1E \rightarrow 2^1S$ . These bands, consisting of *P* and *R* branches, start in the ultraviolet between 3620 and 3700 Å. U. and include nearly all the strong lines in that region of the spectrum. By coordinating the 4-quantum systems with the proper 3-quantum systems it is possible to represent the  $\nu_0$  lines by a Rydberg formula, thereby evaluating the electronic terms and making possible the calcn. of the ionization potential of the  $H$  mol. By the formulas of the old quantum mechanics an ionization potential of 15.381 v. is derived for  $H_2$ , and 15.235 v. by the wave mechanics. These values, however, give practically the same value, 4.465 v., for the heat of dissocn. of  $H_2$ . C. C. KRESS

Titanium oxide bands in the orange, red and infra-red region. F. LOWATER. Coll. of Science, South Kensington. *Nature* 123, 644(1929).—Bands in the region of  $\lambda 5600$  to  $\lambda 8000$  have been analyzed into at least 2 systems, distinct from that of the blue-green region, previously analyzed by Birge and Christy (*C. A.* 22, 4063, 4369). One of these in the orange is a singlet system due to the electronic transition  $^1P - ^1S$ , the other a triplet system in the red and infra-red due to the transition  $^3S - ^3P$ . Of the former only 1 sequence has been found; of the latter, 4 have been detd., namely, the (0,1), (9,0), (1,0) and (2,0), the  $\Delta\nu$  sepns. of the triplet heads of the (0,0) sequence being 66.7 and 74.6  $cm^{-1}$ , resp. The mol. const. detd. from the vibrational analysis of the triplet system show that in the final state the vibrational frequency of the rotationless mol. with infinitesimal amplitude of vibration is the same as that in the blue-green system, and that thus their final energy level,  $^3P$ , is the same. Further, since the sepns. of the triplets of red-infra red system pertains to this final level, it pertains also to the final level of the blue-green system. Analysis of the other bands found in the red is in progress. G. CALINGAERT

A new band system of carbon monoxide ( $3^1S \rightarrow 2^1P$ ), with remarks on the Ångström band system. R. C. JOHNSON AND R. K. ASUNDI. King's College, Univ. of London. *Proc. Roy. Soc. (London)* A123, 560–74(1929).—A new system of four CO bands has been observed with heads at 3680, 3893, 4125 and 4380 Å. U. These bands, consisting of *P*, *Q* and *R* branches, represent the electronic transitions  $3^1S \rightarrow 2^1P$ , and have a structure similar in every respect to the Ångström system which results from the transition  $2^1S \rightarrow 2^1P$ . Detailed analyses of the fine structure are given for the (0,1), (0,2) and (0,3) bands of the new system, and also for the 4511 and 4123 Å. U. bands of the Ångström system. From the analyses the const. of the  $3^1S$ ,  $2^1S$ , and  $2^1P$  levels of the CO mol. have been detd. These data, including the moments of inertia and the nuclear sepns. of the mol. in the different energy states, are presented in a table. C. C. KRESS

The absorption band spectrum of chlorine. A. ELLIOTT. *Proc. Roy. Soc. (London)* A123, 629–44(1929).—New wave-length measurements have been made of the absorption bands of  $Cl_2$  obtained by passing white light through a one-meter column of the gas at 1 atm. The bands consist of *P* and *R* branches and are due to the mol.  $Cl_{35}Cl_{35}$  and  $Cl_{35}Cl_{37}$ . In the mol. with equal nuclear masses the band lines show an alterna-

tion in intensity, which is not present in the bands of the non-sym. mol.  $\text{Cl}_2\text{Cl}_{17}$ . The analysis of these bands according to the usual procedure gives data for the rotational consts., moments of inertia, and internuclear distances of the mols. From these it is seen that absorption of a quantum of energy expands the normal  $\text{Cl}$  mol. considerably; and that although the sym. and non-sym. mols. have different moments of inertia yet their internuclear seps. are the same. C. C. KIESS

The photographic measurement of the relative intensities of the  $L_{\alpha_1}, \alpha_2, \alpha_3$  lines of silver. H. C. WEBSTER. Univ. of Melbourne. *Proc. Phys. Soc. (London)* **41**, 181-91(1929).—The relative intensities of the  $L_{\alpha_1}, \alpha_2, \alpha_3$  lines of Ag were detd. by a method of photographic photometry. Although it is difficult to deduce intensities of x-rays from the blackening produced in the photographic emulsion, yet the photographic method gives a permanent record and makes it possible to get results for weak lines because the photographic effect is cumulative. The intensity of an x-ray line of frequency  $\nu$  is defined as the no. of quanta of characteristic radiation of this frequency which proceed per sec. from the anticathode of the tube. By measuring, with a Moll microphotometer, the densities of the Ag lines produced by a vacuum spectrograph, for different exposure times, the following intensity ratios were found:  $L_{\alpha_1}:L_{\alpha_2} = 100:12.0$ ;  $L_{\alpha_1}:L_{\alpha_3} = 100:4.6$  to  $100:7.3$  according to tube voltage. Not so accurate is the value of the ratio 100:40 found for  $L_{\alpha_1}:L_{\beta_1}$ . C. C. KIESS

Spark satellites of the  $L_{\alpha}$  lines of silver. H. C. WEBSTER. Univ. of Melbourne. *Proc. Phys. Soc. (London)* **41**, 192-3(1929).—Four spark satellites of Ag were observed on the hard side of  $L_{\alpha_1}$  on photographs obtained with a vacuum spectrograph. Their wave lengths in X units detd. with reference to  $L_{\alpha_2}$  are:  $\alpha'_2, 4134.7$ ;  $\alpha'_1, 4130.5$ ;  $\alpha''_2, 4125.6$ ;  $\alpha''_1, 4119.0$ . C. C. KIESS

Excitation of mercury vapor by the resonance line. LORD RAYLEIGH. *Nature* **123**, 488(1929); cf. *C. A.* **22**, 4065.—The light emitted by Hg vapor which has been excited by 2537 is this same light, i. e., simply resonance radiation. In the expts. with a blast of vapor with air at 9 mm. in the tube its source can be observed as sepd. in space from the source of the continuous bands, which are doubtless of mol. origin. However, *in vacuo* the resonance radiation itself can be observed a considerable distance from its origin. This would show that the interval between excitation and emission is under some conditions enormously longer than  $10^{-7}$  secs., as usually assigned. If so, many views held at present will need revision. GEORGE GLOCKLER

Optical determination of the heat of dissociation of salt vapors. G. H. VISSER. *Physica* **9**, 115-8(1929).—The heats of dissocn. of NaBr, LiF and LiBr were detd. by the optical method of Terenin (*C. A.* **20**, 2788; **21**, 3833) in which  $\lambda_m$  of fluorescence light of a salt vapor  $MX$  irradiated with monochromatic ultra-violet light of limiting  $\lambda_p$  is related by  $h\nu_p = D + h\nu_m$  ( $D$  is heat of dissocn.). From the limiting  $\lambda_p$  which gives fluorescence, a high-powered spectroscopic and monochromatic metal spark light being used,  $D_{\text{opt}} = 82.6 \pm 1.5, 78.4 \pm 2.5, 96.7 \pm 1.4$  cal. as compared with thermochem. data of 90.45, 71.25 and 87.06, resp., for the 3 salts. The agreement, especially for the first 2 salts, is considered reasonable. Addnl. work, however, on TII vapor, previously studied by T., showed that contrary to his observations  $\lambda_p$  changes with temp. and pressure of the salt vapor and all 3 Zn lines (2034, 2064 and 2100) gave fluorescence as shown from a spectrophotogram. From one photogram  $D = 48$  cal. for TII would follow; Terenin's value is 61.1 cal.; the thermochem. value is 58.5 cal., which indicates the inadequacy of the method. At the same time the observations clear up the inconsistency of differences in absorption and emission spectrum of TII found by Terenin with regard to their temp. and pressure influence. B. J. C. VAN DER HOEVEN

The formula for the optical dispersion of quartz. T. BRADSHAW and G. H. LIVENES. Univ. College, Cardiff, Eng. *Proc. Roy. Soc. (London)* **A122**, 245-50(1929).—A review of the various formulas for optical dispersion of quartz is given, many of which have no theoretical significance, while those that do, show deviations in parts of the spectrum. Lowry's latest and most accurate formula,  $\omega = [9.5639/(\lambda^2 - \lambda_1^2)] - [2.313/(\lambda^2 - \lambda_2^2)] - 0.1905$ , where  $\lambda_1^2 = 0.0127493$  and  $\lambda_2^2 = 0.000974$ , is compared with that derived by the authors, which is,  $\omega = [845.694/(\lambda^2 - \lambda_1^2)] - [0.40235/(\lambda^2 - \lambda_1^2)^2] - [838.4320/(\lambda^2 - \lambda_2^2)] - [0.13331233/(\lambda^2 - \lambda_2^2)^2] + [43.05794/(\lambda^2 - \lambda_3^2)] + [2119.117/(\lambda^2 - \lambda_3^2)^2]$ , where  $\lambda_1^2 = 0.01274912$ ,  $\lambda_2^2 = 0.01208000$  and  $\lambda_3^2 = 80$ . The latter formula is slightly more satisfactory than any so far proposed in agreeing with observed data and also provides an explanation of the practically const. effect of the infra-red band. Instead of introducing a new band in the extreme ultra-violet it has only been necessary in this formula to split the old single band into a close doublet. It appears possible to improve the formula when better exptl. accuracy makes it advisable. RAYMOND H. LAMBERT

**Zeeman effect in the spectrum of argon (A II).** C. J. BAKKER, T. L. DE BRUIN AND P. ZEEMAN. *Z. Physik* 52, 299-300(1928).—Slight deviations from the g-sum rule of Landé are corrected (cf. C. A. 23, 38). GEO. GLOCKLER

**The Zeeman effect in the spectrum of ionized argon (A II).** C. J. BAKKER, T. L. DE BRUIN AND P. ZEEMAN. Univ. Amsterdam. *Verslag Akad. Wetenschappen Amsterdam* 37, 562-81(1928).—See C. A. 23, 38. B. J. C. VAN DER HOEVEN

**Retardation of the green fluorescence of mercury vapor.** STEFAN PIENKOWSKI. *Bull. intern. acad. polonaise* 1928, 241-56; cf. C. A. 22, 3097; 23, 337.—By means of the app. previously described, it is detd. that the period of lag in the green fluorescence of Hg which has been excited by ultra-violet rays from Al is of the order of  $10^{-6}$  sec. and diminishes with increase in density of the vapor. Microphotometric curves show that the intensity of luminescence increases from the moment optical excitation starts until it reaches a max. in a period which increases inversely with the density of the vapor ( $4.7 \times 10^{-5}$  to  $1.5 \times 10^{-5}$  sec.). The rate of increase of intensity and rate of extinction increase with the vapor density. These facts confirm the theory that in the green luminescence of Hg a modification of the mol. of this metal takes place because of short wave excitation which causes it when leaving the state of purely optical excitation (incapable of fluorescence) to enter a new state which produces green fluorescence under mol. impacts. C. H. PEET

**Remarks on an ultra-violet luminescence of calcium oxide and calcium sulfide caused by x-rays.** E. RUMPF. *Ann. Physik* 87, 590-4(1928).—An ultra-violet luminescence first found in taking x-ray spectrograms of CaO and CaS has been studied. Two bands appear from CaO; the stronger has a max. between 345 and 375  $m\mu$ , and the weaker has a max. between 320 and 330  $m\mu$ . It is probably due to impurities; the voluntary addn. of traces of Cu and Mn produce wider bands. The luminescence from CaS is about 10  $m\mu$  greater in wave length and much weaker than that from CaO. R. L. HERSHEY

**The formation of phosphorescence centers in calcium sulfide.** F. BANDOW. Heidelberg. *Ann. Physik* 87, 469-508(1928).—The effects of various additions to CaS phosphors have been examd. The studies on  $\text{CaSCu}\alpha$ ,  $\text{CaSMn}\alpha$  and  $\text{CaSBi}\alpha$ , showed that for CaS phosphors as ordinarily produced, the addn. of fluoride is necessary to obtain the max. phosphorescence for a given metal content. The necessary fluoride content for max. phosphorescence decreases with decreasing metal content. Phosphors whose basic material is CaS only have been examined. They show, without additions, the max. phosphorescence obtainable from ordinary sulfides with the sufficient fluoride content. The explanation of the fluoride effect must include some effect upon the heavy-metal atoms. The assumption that the no. of separable electrons per metal atom is changed by the fluoride and not the no. of centers seems to agree best with the facts. Since phosphors having only CaS as a base show the full phosphorescence, it is obvious that the  $\text{CaSO}_4$  content of the usual sulfides hinders the electron sepn. R. L. HERSHEY

**Increase of energy with elementary processes.** H. BRUTLER AND B. JOSEPHY. Kaiser Wilhelm Inst., Berlin. *Z. physik. Chem., Abt. A*, 139, Haber Bd., 482-96(1928); cf. C. A. 22, 1096, 4363, 4369, 4376.—By choosing the right conditions the process is observed that on collision of 2 activated atoms one takes up the combined amt. of energy. The reactions  $\text{Na} + \text{HgCl}_2$ ,  $\text{Na} + \text{Cl}_2$  and  $\text{K} + \text{Cl}_2$  give a typical intensity increase in the spectrum of Hg. The max. is twice the energy of the nascent particles. In the last 2 reactions at. Hg has been mixed in. The heat of formation of 4 mols. of NaCl is needed for the "exciting" of 1 atom of Hg. E. SCHOTTE

**The photochemical reaction between mercury vapor and oxygen.** W. ALBERT NOYES, JR. Univ. Chicago. *Z. physik. Chem., Abt. B*, 2, 445-8(1929); cf. C. A. 22, 2717.—The results obtained in the action between O and excited Hg atoms by N, do not differ greatly from those obtained by Leipunskii and Sagulin (C. A. 23, 1054), but the interpretation of the mechanism of the reaction by the latter is shown to be doubtful from energy considerations. The decrease in pressure during the action is probably due to the formation of  $\text{O}_3$  and to the action of  $\text{O}_3$  with the Hg vapor to form  $\text{HgO}$ . On the basis of exptl. facts a series of reactions is formulated which may explain the mechanism of the action, but a final decision is withheld. H. F. JOHNSTONE

**Absorption spectrum and decomposition of hydrogen peroxide by light.** H. C. UREY, L. H. DAWSEY AND F. O. RICE. *J. Am. Chem. Soc.* 51, 1371-83(1929).—With a H discharge light source, a continuous absorption spectrum was observed for  $\text{H}_2\text{O}_2$ , with no indication of any structure. The absorption begins at 300  $m\mu$  and extends toward the ultra-violet to the limit of the app. used. There was no difference in the absorption of the liquid and vapor states. From the absorption data and the emission spectrum, the decompn. of  $\text{H}_2\text{O}_2$  is shown to be;  $\text{H}_2\text{O}_2 + h\nu = 2\text{OH}$ . W. R. B.

The effect of temperature in retarding the photochemical reactions of colored solutions in benzene. N. ZCHODRO. Inst. of Physics and Biophysics. *J. chim. phys.* 26, 178-81(1929).—Increase of temp. diminishes the rate of decoloration of benzene solns. colored by cyanine and gallocyanine. White light was used, and the course of the reaction followed by means of a spectrophotometer at 15°, 32° and 45.5°. A theoretical explanation is given. MALCOLM DOLE

The chemical effects of x-rays. ST. REINER. Duisburg. *Z. angew. Chem.* 42, 77-8(1929).—Expts. on the base exchange in zeolites under x-ray radiation show that metals may be introduced into desmine, under radiation, which ordinarily do not give rise to base exchange in their salt solns. alone. R. L. HERSHEY

The x-ray photolysis of hydrogen peroxide. ORRO RISSE. Tech. Hochschule, Stuttgart. *Z. physik. Chem., Abt. A*, 140, 133-57(1929); cf. *C. A.* 22, 3841.—The effect of concn. on the x-ray photolysis of  $H_2O_2$  soln. by unfiltered W radiation was investigated in the range 0.001 *M* to 0.25 *M* and an empirical curve obtained. At very low concns. the quantity decompd. varies linearly with the product of intensity and time, and the reaction velocity is practically independent of the concn.; while at high concns. the velocity equation for a monomol. reaction holds fairly well. Since the observed data over the whole range do not fit the equations for mono-, bi-, or tri-mol. reactions, it appears that the reaction is a complicated one, probably involving the action of the  $H_2O$ . The cond. of pure  $H_2O$  changes from 1.5 to  $2.28 \times 10^{-6}$  reciprocal ohms, and the  $p_H$  from 6.0 to 7.0 under intensive radiation from x-rays.  $H_2O_2$  is formed quantitatively in amts. corresponding to the  $O_2$  absorbed in the  $H_2O$  and is absent if the air is completely removed from the  $H_2O$  previously by boiling. There is a continuous increase of the acidity up to 0.5-1% and an increase in the sp. cond. to twice its original value even when the atm. gases are removed. The increase of acidity is greater with ultra-violet light, but in that case there is no formation of  $H_2O_2$  in  $H_2O$  satd. with  $O_2$ . It is formed, however, if  $ZnO$  is present. This shows that the activation of the  $O_2$  is a necessary condition for the formation of  $H_2O_2$  by x-rays. In distinction to its spontaneous decompn. by ultra-violet light  $H_2O_2$  gives off when decompd. by x-rays a combustible gas mixt. with the  $O_2$  in amts. of 1.5-2% of the total gas evolved. This may be  $H_2$ , but its identity was not proved. The formation of at. H and O could not be demonstrated. The temp. coeff. of the x-ray reaction at about  $1/60^\circ N$  was equal to one between 2° and 50°. Strong alkalis and acids limit the decompn. Energy considerations show that in very dil.  $H_2O_2$  solns. about 70 kg.-cal. is necessary for the complete decompn. of one mol.; but this value becomes less with increasing concn. A. W. KENNEY

The action of x-rays on ferrous sulfate solutions. HUGO FRIEKE and STERNE MORSE. *Phil. Mag.* [7], 7, 129-41(1929).—The authors studied the effect of various doses of x-rays upon solns. of  $FeSO_4$  in concns. 0.001 *M* to 0.00004 *M*.  $FeSO_4$  was oxidized by exposure to x-rays and the amt. transformed increased in direct relation to the diln. Very high dilns. were therefore used in quantities of 1 or 2 cc. A refined electrometric titration method was developed to det. the small changes which occurred. The exposure to x-rays was made in a small cell placed 20 cm. from the target in the x-ray tube, the width of the x-ray beam being a few mm. wider than the cell itself. The x-ray intensity during irradiation of the cell was controlled by placing a small specially constructed ionization chamber directly beneath the cell. The solns. were satd. with air before irradiation and contained 0.8 *M*  $H_2SO_4$ . The abs. amt. of  $FeSO_4$  transformed was directly proportional to the x-ray doses (expressed in arbitrary units) up to a dose of 29.0. Above a dose of 29.0 the relationship is again linear but when the values are plotted the slope of the curve is only half of that observed below a dosage of 29. The no. of mols. of  $FeSO_4$  transformed by dose 29 was equal to the no. of equivs. of gaseous  $O_2$  dissolved in the solns. It was assumed that the oxidation of ferrous ions was a secondary effect due to activated water mols. which were produced by secondary x-ray electrons. This receives confirmation when it is found on calcn. that twice as many ferrous ions are changed in the presence of dissolved  $O_2$  as compared to its absence, when related to the no. of pairs of gaseous ions produced by the same x-ray energy in air. A similar relation appears when the calcn. is made in comparison to water mols. transformed in pure water. Some evidence is presented for the formation of small quantities of  $H_2O_2$ . In the very dil. soln. an apparent reversal of the reaction takes place when only a trace of ferrous ion remains unconverted. L. H. REYERSON

Active nitrogen. V. The decay of the nitrogen after-glow. ERIC J. B. WILLEY. *J. Chem. Soc.* 1929, 228-31.—An error in the calcn. of W.'s previous paper (*C. A.* 22, 3839) led to an incorrect conclusion as to the process of the decay of the N after-glow. By correcting this error, the reaction in question is shown to be a ternary process

represented by the equation  $2N + N_2 \longrightarrow 2N_3$ . This reaction is complicated by a surface reaction taking place at the same time as that in the bulk of the gas. A. G.

Radioactive liquid. E. SOMMER. *Swiss* 127,544, Aug. 15, 1927. Vessels are made of porous thin-walled material contg. radio active salts to impart radioactive properties to the liquids contained therein.

Luminous composition. J. A. F. BEAVIS. *Brit.* 299,228, Dec. 22, 1927. Phosphorescent or luminous salts such as alk. earth sulfides or complex mixts. of such sulfides or of Al with salts of Bi, Th, Tl, U and alkali metals are ground with a resin or resinous compn. and the product is mixed with suitable solvents, diluents or vehicles which may comprise fatty oils, cellulose derivs. or rubber as addnl. ingredients.

## 4—ELECTROCHEMISTRY

COLIN G. FINK

The beginnings of electrochemical activities. J. LYMAN SHEEHAN. *Pamphlet, Am. Electrochem. Soc.*, May, 1929, 13 pp.—Starting with the observation of frictional electricity by Thales of Miletus (600 B. C.), the history of electricity and electrochemistry is followed through the centuries. Particular emphasis is placed upon the researches of Galvani, Volta, Davy, Faraday and Berzelius. C. G. F.

Electrochemical education in England. E. O. JONES. *Pamphlet, Am. Electrochem. Soc.*, May, 1929, 16 pp.—There are only 2 institutions in England which have definite specialized courses in electrochemistry, the Imperial College, which provides a post graduate course for those who have already graduated with honors in chemistry, and Manchester (College of Technology), which awards a B.Sc. (Tech.) in this subject. Facilities exist, however, at many of the higher institutions for the teaching of this subject. At most English universities theoretical electrochemistry is incorporated in the instruction in phys. chemistry, and no more than brief references to technical applications will occur at appropriate points in the other courses. Although electrochemistry does not, at the present time, occupy an important place in the curricula of the

English universities, need for such instruction has not been overlooked. Judging from the information supplied with regard to the openings available, the facilities offered adequately satisfy the present demands, but it is reasonable to anticipate that the government's policy of electrification will increase this demand, and that in the future increasing attention will be paid to applied electrochemistry, and that important schools in this subject will develop as the need arises. C. G. F.

**Electric furnaces for the heat treatment of steel.** J. SAUER. *A. E. G. Mitt.* 1928, 165-71; *Science Abstracts* 31B, 494.—S. describes and illustrates the 2 chief types of elec. furnaces for the heat treatment of steel, *i. e.*, the resistor furnace with chrome-Ni alloy heating elements suitable for temps. up to 1000°, and the "salt-bath" type for temps. up to 1300°. The salt-bath furnaces are subdivided into those in which the salt is heated by a sep. metal-heating element, and those which, after the salt has been heated to fusing point, maintain their temp. by the passage of current through the mass of the salt. The salts generally used consist of a mixt. of Ba and K chlorides for temps. up to 1000° and of BaCl<sub>2</sub> alone for 1300°, while for tempering operations up to 400° KNO<sub>3</sub> is used. For cementation purposes special mixts. are employed, which enable the surface of the steel to be impregnated to a depth of 1/2 mm. The temp. regulators embodied in the furnaces are able to hold the internal temps within the limits of  $\pm 10^\circ$ . Reference is also made to special furnaces on the Wild-Barfield system. H. L. D.

**The manufacture of ferrosilicon in the electric furnace.** JAMES SILBERSTEIN. *Can. Chem. Met.* 13, 91-3, 94(1929).—A comprehensive account of furnace design, construction and operation for Fe-Si manuf. A furnace of 3000-6000 kw. is considered most suitable. Disadvantages of larger units are: (1) the amount of energy not in use during furnace shutdown, (2) difficulty of furnace repairs, and of electrode replacements due to the higher heat and (3) difficulty of keeping a large furnace from blowing. Three octagonal electrodes are employed; the bottoms are made of some form of C; a life of 1 1/2-3 yrs. for continuous operation, and less for intermittent operation, is usual. The characteristics of graphite, amorphous C and self-baking electrodes are pointed out. The greater % of Fe-S produced is the 50% alloy. Raw materials, charging, furnace operation and product are briefly discussed. The cost of manuf. depends chiefly on price of elec. power. The power consumption in 2000-4000-kw. furnaces ranges from 2.1-2.6 kw. hr. per lb. when coke is the reducing agent; electrode consumption is 3-6 lbs. per 100 lbs. Fe-Si when amorphous C electrodes are used, and 2-4 lbs. when Soderberg self-baking electrodes are used. Intermittent operation does not impair the quality of the product. Fe-Si is chiefly used as a steel deoxidizer. 75-90% ferrosilicon is used for 4% Si steel and for Fe-Si alloys contg. over 15% Si. W. H. BOYNTON

**Sponge iron, a raw material for electric steel.** N. K. G. THOLAND. *Pamphlet, Am. Electrochem. Soc.*, May, 1929, 22 pp.—Sponge Fe is now commercially produced in Sweden. When considered as a base for the manuf. of com. and highest grade steels in place of scrap or pig Fe, the specific properties of the various grades of sponge Fe must be taken into account. Scrap nowadays contains foreign metals, such as Ni and Cu; pig Fe is high in C and in impurities difficult to eliminate completely during steel making. Sponge Fe can be made free from Si and very low in C, S and P. Numerous comparative figures are shown, based on actual heats in the elec. furnace. The phys. properties of steels made with sponge Fe excel those of steels made from scrap or pig Fe. C. G. F.

**A new small-capacity electric furnace.** ANON. *J. four élec.* 38, 117-8(1929).—Illus. A new type furnace combines the advantages of radiation and Heroult furnaces. The electrodes are guided across the arch and enter the furnace at a certain angle, which can be changed during operation. The furnace is started by striking an arc between the electrodes; the heating is then changed to direct arc heating. M. McMAHON

**A new ultra-rapid regulator for electric arc furnaces.** ANON. *J. four élec.* 38, 119-26(1929).—The regulator described consists of a solenoid, an oil auxiliary engine fed by the pump; the piston of this engine acts with a lever-distributor of water of the pump under pressure—feeding the lifting jack, which controls the electrodes. The advantages of this type of regulator are reviewed. M. McMAHON

**The electrometallurgical plant at Chateau Feuillet.** ROBERT SEVIN. *J. four élec.* 38, 45-50(1929).—Illustrated description of elec. equipment of plant designed for the manuf. of carbide and Fe alloys, transformers, furnaces, etc. M. McMAHON

**The electrical conductivity of Carborundum.** H. J. SEEMANN. *Physik. Z.* 30, 143-4(1929).—Resistance measurements were made with 6 selected crystals of Car-

borundum at room temp. and at  $-80^{\circ}$ . The ratio  $R_{-80^{\circ}}/R_{-17^{\circ}}$  lies between 4 and 6. The sp. cond. is about 0.1 mho. Conclusion: Carborundum exhibits partly electrolytic and partly metallic conductance.

E. R. SMITH

The base load central station, and its future relation to the electrochemical industry (electrolytic hydrogen). FARLEY G. CLARK. *Pamphlet, Am. Electrochem. Soc.*, May, 1929, 7 pp.—There are available in the U. S. and Canada large quantities of surplus energy, at costs varying from 0.12 to 0.35 cent per kw.-hr. This surplus energy can be converted into a steady supply of a readily usable commodity, namely,  $O_2$  and  $H_2$  gas, by the electrolysis of  $H_2O$ . The manuf. and sale of these gases should become a normal function of the utility companies. At 0.12 cent per kw.-hr. the 2 gases together will cost 22 cents per 1000 cu. ft. (0.78 cent per cu. m.).

C. G. F.

Current efficiencies and watt efficiencies in water electrolysis. R. NITZSCHMANN. *Metallbörse* 18, 1352(1928).—Graphs and tables only are given.

F. M. SYMMES

Frequency and arcing in the alternating current electrolysis of water. J. W. SHIPLEY. *Trans. Am. Electrochem. Soc.* 55 (preprint), 11 pp.(1929).—The rate of generation of electrolytic gases, using NaOH soln. as electrolyte and with frequencies from 0 up to 300 cycles, was detd. for a. c. electrolysis of  $H_2O$ , with Pt, Cu and Ag electrodes. The electrolytic capacity at const. frequency was const. for Cu, but varied with the quarter-wave area for Pt and Ag. The electrolytic capacity of the electrodes at all frequencies is represented by the equation  $Q_0 = Aq_1^n$ , where  $Q_0$  is the av. storage capacity of the electrodes,  $q_1$  is the quarter-wave area, and  $A$  and  $n$  are electrolytic absorption consts. for the metal. The electrolytic capacity at const. quarter wave area decreased to a min. with increasing frequency. Electrolysis at voltages above 110 gave rise to the thermal decompn. of the water by arcing on the electrodes. This decompn. amounted at high voltages (4,200) to more than 13 times that required by Faraday's law. Arcing, with its accompanying decompn. of  $H_2O$ , can be suppressed by applying external pressure, and thus preventing the formation of steam bubbles on the electrodes. This suggests that elec. boilers should operate under pressure, and that the hot  $H_2O$  be permitted to boil in a second chamber at a lower pressure.

C. G. F.

The electrolytic refining of lead containing bismuth. PAUL SCHACHTERLE AND W. RIECKE. *Bergakademie Clausthal. Metall u. Erz* 25, 637-40(1928).—Pb contg. Bi may be refined by electrolyzing from  $PbS_2O_6$  soln., prepd. (1) by passing  $SO_2$  through  $MnO_2$  (100 g.) and  $H_2O$  (400 cc.) at temps. below  $0^{\circ}$ , and adding  $PbO_2$ , the  $PbS_2O_6$  formed being equiv. to 80% of the  $MnO_2$  going into soln., or (2) by passing  $SO_2$  into an  $Fe(OH)_3$  suspension, coagulating with  $H_2O_2$  and adding  $PbO_2$ . The electrolysis is carried on between an Al (or Pb) cathode and a soft Pb anode, in a soln. contg. 60-90 g. Pb (as  $PbS_2O_6$ ) and 15-30 g.  $H_2S_2O_6$  with an org. addn. agent. Good deposits are obtained with the use of pyrogallol (0.22 g./500 cc. of electrolyte) and gelatin (0.036 g./500 cc.) as addn. agents, while with the addn. of dextrin, starch, glycerol, gum arabic, sugar and gelatin + glycerol, they are unsatisfactory. On electrolyzing, the Bi, Cu and Ag present in the crude Pb remain in the slime, while Sn, Sb and As are also present in the electrolyte. This must be as free as possible from Fe and not too poor in Pb. The purification of the electrolyte may be attained by pptg. the Fe present with  $PbO_2$ .

J. BALOZIAN

Steel anodes for chromium plating. E. M. BAKER AND E. E. PETTIBONE. *Metal Ind.* (New York) 26, 520-1(1928); cf. *C. A.* 22, 3844.—A comparison is made of steel and electrolytic Fe anodes in a chromic acid Cr-plating bath. A graph shows that electrolytic Fe is more resistant to corrosion than mild steel, and still more resistant than moderate and high-C steels. The decrease in anode current efficiency with age is more pronounced with the more impure anodes, which is probably due, in part at least, to a protective oxide or chromate coating formed by the continued passage of current. The effect of anode compn. on ratio of trivalent to hexivalent Cr is indicated at various c. ds. with the different kinds of anodes. C from 0 to 1.9 apparently has no effect on the ratio of trivalent to hexivalent Cr in the bath. The C in the anode increases the rate of anode soln., the effect of a small increase being marked, when the Fe is most nearly free from C.

W. H. BOYNTON

Details of cadmium plating. OTTO H. LOVEN. *Metal Ind.* (New York) 27, 224-7 (1929); cf. *C. A.* 23, 2665.—An outline of methods, equipment and precautions necessary to procure a good Cd plate. The resistance of a Cd plate is quickly detd. by means of the acetic acid peroxide test. A one-l. graduated flask is filled  $\frac{1}{2}$  full of water and 35 cc. glacial AcOH added. After shaking, it is transferred to a beaker or crock, 10 g.  $Na_2O_2$  added gradually with const. stirring till soln. is complete. It is returned to the graduated flask and filled to the mark at  $18^{\circ}$ . A few plated pieces

are covered in a dish with the test soln. A brown discoloration appears and the time required for the development is compared by means of a table to the equiv. no. of hrs. salt spray test.

W. H. BOYNTON

**Measurements of hydrogen-ion concentration in plating baths.** R. E. BREWER AND G. H. MONTILLON. *Trans. Am. Electrochem. Soc.* 55 (preprint) 25 pp. (1929).—The  $p_H$  of representative acid plating baths has been measured successfully by the electrometric method, different kinds of indicator electrodes being used. The theory of the electrodes used— $H_2$ ,  $O_2$ , quinhydrone, Sb and  $PbO_2$ —is discussed. The calibration of the  $O_2$  and Sb electrodes, together with the equations for their calibration curves against the normal calomel electrode, is given. Conditions for the best exptl. procedure have been established, as well as the limitations of the various electrodes, in typical Ni, Co, Fe, Zn and Cr plating baths. A comparative study of the results of electrometric and colorimetric methods of measuring H-ion concn. has been made. Titration curves have been constructed from data obtained by adding known vols. of standard acid or alkali soln. to a measured vol. of the bath, observing by electrometric and colorimetric methods the resulting  $p_H$  after each addn., and plotting the results. Comparison of the curves obtained in this way with similar curves of other investigators and a discussion of the significance of the curves are given. Measurements of  $p_H$  have been made by a simple buffer comparison method. Comparison of these results with measurements made on the same baths, employing the colorimetric "drop-ratio" and the usual electrometric methods using different kinds of electrodes, shows the reliability and utility of this procedure. The method provides for rapid cross-checking of all measurements, and eliminates the need of the usual reference electrodes except for preliminary checking.

C. G. F.

**Nickel-chromium process.** W. PFANHAUSER. *Chem.-Ztg.* 53, 207-8(1929).—A discussion of the application of Cr plating with an intermediate Ni plate. It is essential that the Ni plate be sufficiently low in H, that it can take up the addnl. H deposited with the Cr plate without peeling off. Under these conditions, the Cr can be deposited at such high c. d. that the time in the Cr bath can be reduced to 5-10 mins. The  $p_H$  of the Ni bath should be between 5.2 and 5.8, the thickness of Ni deposited generally running from 0.02 to 0.025 mm. Temps. of 35-40° are recommended. It is exceedingly important that the surfaces to be plated be first thoroughly cleaned.

H. STOERTZ

**Electrodeposition of copper. An historical note.** F. A. J. FITZGERALD. *Pamphlet, Am. Electrochem. Soc.*, May, 1929, 4 pp.—In order to incorporate changes in maps that have been engraved on Cu plates, Wheatstone suggested that instead of hammering up and filing away the section to be changed it should be filled up with an electrically conducting material ready for the new engraving. The Cu deposited, however, turned out to be too brittle to stand the pressure of the printing process. William Dalglish overcame this brittleness by placing a plate of smooth Cu horizontally on the bottom of the electrolyzing dish, and suspending over it at a short distance the plate of Cu to be deposited on. With the aid of a mech. device, he kept the dish rocking, and therefore the electrolyte was always in motion. The deposited Cu was hard, elastic, and much more homogeneous than that deposited when the liquid was at rest. It stripped off the matrix satisfactorily. The speed of the movement of the liquid was the important factor in the deposition of the Cu. These expts. resulted in large-scale equipment, which was used by the government in Ireland for more than 20 years.

C. G. F.

**An experimental study of the electrochemical polarization of platinum.** E. I. SHEPITALSKII AND V. V. PICHETA. *J. Russ. Phys.-Chem. Soc.* 60, 1351-81(1928).—The use of S.'s commutator (cf. C. A. 19, 1356) made it possible to measure the e. m. f. of the cell  $(PtO_2 | 1 N H_2SO_4 || 1 N H_2SO_4 | 1 N H_2SO_4, Hg_2SO_4 | Hg)$  while the current was flowing through it ( $Sp$ ) as well as at certain time intervals after opening the circuit ( $Pot$ ). A H-vessel contd. the electrodes, the anode being a loop of polished Pt wire and the cathode a platinized Pt plate. There was a const. flow of 1 N  $H_2SO_4$  (2 cc. a min.) from + to -. The auxiliary Hg cathode was connected by a capillary bridge to the - leg of the vessel. Resistance bridge, Weston cell and Einthoven's string galvanometer were used in the measurements; the Pt-Hg cell was placed in a thermostat at 0° or 18°. Rapid rotation of the anode did not influence the depolarization curves.  $Sp$  increased with the c. d. while  $Pot$  decreased. Both changed irreversibly when the current was first increased to 60 milliamps. and then reduced to 3 milliamps.;  $Pot$  changed reversibly with subsequent variations in the current strength. A study of Pt wires of varying thickness and previous history as the anodes showed that the values of  $Sp$  and  $Pot$  are each detd. by a distinct process. The introduction

of a chem. depolarizer  $\text{Fe}^{++} \rightleftharpoons \text{Fe}^{+++}$  caused a gradual rise in *Pot* while *Sp* was not changed; when the anode was rotated, *Pot* instantly dropped below the previous value while *Sp* declined only slightly. Conclusion: *Sp* does not represent the physico-chem. phenomena at the anode (soln. of  $\text{O}_2$  and  $\text{O}$  in Pt, formation of indefinite compds. of Pt and  $\text{O}$ ), the latter being closely connected with the changes in *Pot*. B. S.

**Electroplating plant.** J. W. PERRING. *Metal Ind.* (London) 34, 345-6, 375-6 (1929).—A brief description of various types of vats, of methods of heating solns. and of a plating shop layout. The "trussed beam" method of preventing sagging is better than the use of uprights. The employment of a false bottom in plating vats would permit rapid recovery of work. The porosity is a drawback to earthenware vats. Where Fe vats are employed for Cr solns. and the work is liable to approach the sides, it is well to hang sheets of glass around the sides. Rough glass contg. wire netting is satisfactory. W. H. BOYNTON

**Some possible uses of alternating currents in electrodeposition.** H. C. COCKS. *Metal Ind.* (London) 34, 396-8, 414, 424-5 (1929).—A paper dealing principally with the electrolysis by a. c. in which metal deposition does not occur. The amts. of electrochem. effects of a. c. alone are dependent on c. d., those of superimposed a. c. on the ratio of the alternating to the direct component of the current, while the effects of both types of current are greatly influenced by the frequency. Exptl. work shows that the superposition of an a. c. on a d. c. electrode process tends to reduce any irreversibility in that process. Superposed a. c. acts as a depolarizer: it reduces anode and cathode polarization and electrochem. passivity. Chem. depolarizers may leave undesirable decompn. products in the electrolyte, but superposed a. c. will not. Superposition results in marked reduction of  $\text{O}_2$  overvoltage and electrochem. passivity of anodes. Work done on the effects of superposed a. c. in processes involving metal deposition is briefly discussed. The effects are noted for Ni plating, and in combined Zn and Ni plating from a feebly acid soln. of Zn and Ni sulfates. Superposition of a. c. assists the anodic soln. of Cr in acid and alk. solns. The only case of the tech. use of superposed a. c. in electrolysis is that of the Wohlwill modified Au-refining process (Brit. pat. 6,276 (1909)). The introduction of the a. c. in the Wohlwill process converted it from a lab. curiosity to a com. success. The sole effect of the a. c. was on the soln. of the anode and it is very remarkable. Recent proof of the desirability of the presence of chlorides in Ni plating baths and of the employment of temps. of 30-50° tend to discount the outstanding advantages of superimposed a. c. W. H. B.

**Service tests of the mercury arc rectifier.** J. VON ISSENDORFF. *Elektrotech. u. Maschinenbau* 47, 353-7 (1929).—Seven illus. C. G. F.

**Vacuum tubes as oscillation generators.** VIII. D. C. PRINCE AND F. B. VOGDES. *Gen. Elec. Rev.* 32, 288-94 (1929); cf. C. A. 23, 311.—Calcs. for circuit with square current waves agree with its actual performance. M. McMAHON

**Edison's first commercial lamp.** CHAS. L. CLARKE. *Gen. Elec. Rev.* 32, 239-42 (1929).—An historical review of the introduction of Edison's incandescent lamp, its initial installations and early tests. Illustrated. M. McMAHON

**Units of electrical measurement.** G. W. VINAL. *Trans. Am. Electrochem. Soc.* 55 (preprint) 15 pp. (1929).—The elec. units and standards, which were the subject of extended investigation 20 years ago, and thought to be satisfactory for many years to come, are again requiring attention. The relation of the international elec. units to the abs. system of units, which they are intended to represent, is known now to a higher accuracy than when they were established. Differences have been found that will become increasingly serious as science and industry advance. C. G. F.

**Electric batteries.** ANDRÉ HELBRONNER and ERIC DUTT. Fr. 650,923, Aug. 11, 1927. In ordinary or dry batteries using insol. ferricyanides (of Zn, Cu, Ag, etc.) the 2nd electrode is formed of an element high in the electrochem. series such as Zn. The electrode may be  $ZnCl_2$ ,  $ZnSO_4$  or a double cyanide of Zn and Na, etc. Cf. C. A. 23, 2108.

**Electric batteries.** ANDRÉ HELBRONNER and ERIC DUTT. Fr. 651,164, Aug. 24, 1927. An anhyd. or hydrated sesquioxide of Ni, Co, V, etc., or peroxides (U, etc., but not Mn) are used as depolarizing agents in ordinary or dry batteries.

**Electric batteries.** P. PÖRSCKE. Brit. 299,591, July 8, 1927. Porous electrodes are formed by mixing metals and metallic oxides, such as Co oxide and Zn powder, with an acid or base such as NaOH to effect local galvanic action with sepn. of one or more constituents of the mixt. and consequent development of porosity. The mixt. may be heated on a supporting plate. Various mech. details are described.

**Bituminous insulating and sealing composition for electric batteries.** BATTERIEN-UND ELEMENTE-FABRIK SYSTEM ZEILER A.-G. Brit. 299,381, July 22, 1927. A saponifiable material such as wax or resin is mixed with soda lye or the like in insufficient quantity to produce complete saponification; unsaponifiable substances such as paraffin or pitch also are added. Water is removed by heating and fillers such as heavy or light spar may be added.

**Storage battery.** WILLIAM MORRISON (to Vesta Battery Corp.). U. S. 1,712,897, May 14. Structural features.

**Storage batteries.** FRANZ PETRIK. Fr. 651,662, Mar. 24, 1928. Method of fixing the plates and poles.

**Storage batteries.** ANDRÉ A. TOUZOT. Fr. 650,401, Mar. 3, 1928. The sheets of cellulose or cellulosic material used for sepg. the plates of storage batteries are impregnated with sol. mineral substances capable of pptg. an insol. element, such as alkali silicates, which may be followed by a pptn. of  $BaSO_4$  or  $CaSO_4$ . By this means deformation by the electrolyte is avoided.

**Lead-plate storage battery.** GEORGE W. HEBBELER. U. S. 1,712,822, May 14. Structural features. U. S. 1,712,823-4 also relate to connectors for batteries.

**Battery electrodes.** ORTO GERGACHEVICS. Ger. 475,294, Dec. 2, 1926. Battery electrodes of the kind prepd. from a mixt. of CuO and graphite are more easily regenerated if an addn. of retort carbon is made to the initial compn. A suitable compn. comprises CuO 80, graphite 30, powd. retort carbon 110 and water 25 parts.

**Composition for molded battery boxes.** JUNJIRO SATO and TSUNAJI SATO. U. S. 1,711,544, May 7. Powd. elaterite 1, gilsonite 25, blown asphalt 24, silex 23 and asbestos 27%.

**Electrolytic cell for reducing mannose to mannitol or for other reductions of sugars, etc.** HENRY J. CREIGHTON (to Atlas Powder Co.). U. S. 1,712,951, May 14. An aq. soln. contg. 15-25% of mannose and 5% of  $Na_2SO_4$  is placed in the cell, on top of the Hg cathode, and the  $PbO_2$  anode, contained in a porous cylinder, is surrounded with an aq. soln. contg. 5% of  $Na_2SO_4$ , the levels of the solns. being the same. An elec. current having a strength of one and one-half amperes for every sq. dm. of cathode surface is passed through the cell, the Hg cathode being vigorously agitated by the agitator. Nascent H is formed and reduces the mannose to mannitol. Other electrolytes may be used such as  $K_2SO_4$ ,  $Na_2CO_3$ ,  $MgSO_4$  or  $Ca(NO_3)_2$ ; the app. may be employed for effecting various electrolytic reductions.

**Apparatus for reduction of mannose, glucose and other sugars.** HENRY J. CREIGHTON (to Atlas Powder Co.). U. S. 1,712,952, May 14. The app. consists of an electrolytic cell, A, in which alkali metal amalgam is formed, a reduction cell, B, in which the sugar in aq. soln. is reduced by the amalgam, and a reservoir contg. a supply of Hg. When the amalgam attains a desired concn. of alkali metal, it is run into the sugar soln., where it falls to the bottom of the reduction cell. The dilute amalgam and the sugar soln. are then stirred vigorously by means of a stirrer to which are at-

tached 2 blades, which are disposed in the sugar soln. and the Hg, resp. The place of the amalgam used is taken by fresh Hg, which is added from the reservoir, and this pure Hg is converted into another supply of dil. amalgam. After the amalgam added to the sugar soln. has been decomposed by the action of the water, some of the resulting Hg is drawn off into the reservoir, a further quantity of amalgam is run from cell A to cell B, and the proper amt. of Hg is transferred from the reservoir to cell A. This process is continued until the sugar has been reduced. From time to time the electrolyte in cell A is renewed. The Hg may be transmitted from the reservoir to cell A by means of a centrifugal pump.

**Photoelectric cell with gas filling and glow discharge.** TELEFUNKEN GES. FÜR DRAHTLOSE TELEGRAPHIE M. B. H. (August Karolus and Fritz Schroeter, inventors). Ger. 475,113, Jan. 9, 1926.

**Accumulator battery.** MAURICE CHARLES. Ger. 475,432, May 18, 1927. Constructional features.

**Accumulators.** COMPAGNIE GÉNÉRALE D'ÉLECTRICITÉ. Fr. 651,305, Jan. 28, 1928. In accumulators having an alk. electrolyte, pairs of plates composed of tubes or pockets filled with active matter are surrounded with frames made by folding a metal sheet so that the 2 frames for each of the plates of a pair and the junction between the plates are obtained in one piece.

**Accumulators.** SIEMENS-SCHUCKERWERKE A.-G. Fr. 650,240, Mar. 1, 1928. Method of charging and discharging simultaneously.

**Accumulator plates.** I. G. FARBENIND. A.-G. (Georg Kränglein and Richard K. Muller, inventors). Ger. 475,242, May 25, 1927. Plates of a Pb alloy having a framework or skeleton of Pb are electrolyzed in an acid bath until free from the accompanying metals and, if pos. plates are being prepd., are simultaneously oxidized to  $PbO_2$ . Electrolysis at ordinary temp. in a bath of  $H_2SO_4$  of sp. gr. 1.10 and with a c. d. of 1.2 amps. per sq. dm. is suitable.

**Electrodeposition of chromium.** F. LAUTERBACH (to W. G. Poetzsch). Brit. 299,395, Oct. 25, 1927. A small proportion of  $Li_2O$ ,  $Li_2CO_3$ ,  $Li_2SO_4$ , or other suitable Li compd. is added to an electrolyte rich in chromic acid to improve its "throwing power." Li is not deposited. A c. d. of 4-20 amps. per sq. dm. and a temp. of 28-40° may be used for the Cr deposition.

**Electrodeposition of nickel, etc.** SOC. ANON. LE NICKEL. Brit. 299,375, April 13, 1927. Metals such as Ni are deposited on wires or thin rods instead of plates, in order to obtain a dense deposit. The cylindrical billets thus formed are suitable for casting in pots.

**Electroplating apparatus with a perforated rotatable and tiltable receptacle for articles to be plated.** JOSE L. MUJICA. U. S. 1,712,674, May 14. Structural features.

**Electric control system for electroplating apparatus.** LAWRENCE C. TURNOCK. U. S. 1,712,284, May 7.

**Internal chromium plating of rifle barrels or other hollow articles.** J. Q. MACDONALD AND W. M. SCOTT. Brit. 299,298, Oct. 22, 1927. Relative motion between the work and the electrolyte is maintained, at least initially, as by causing flow of electrolyte through the article being internally plated around an accurately spaced and tensioned rod or wire anode.

**Electrometallurgy.** TURE R. HAGLUND. Ger. 475,173, Sept. 3, 1924. Oxides of metals such as Cr, Fe, Mn, Ti, V, W and Mo are reduced in an elec. furnace with briquets prepd. from a carbonaceous reducing agent and a slag-forming oxide such as  $Al_2O_3$ ,  $MgO$ ,  $BaO$ , or  $CaO$ . The slag produced may be briquetted with carbonaceous reducing agent and used again. Reducing agents of low sp. gr. are preferred, e. g., coke or wood charcoal.

**Pure aluminum.** ALUMINIUM-IND. A.-G. Ger. 466,278, Feb. 5, 1928. Pure Al is obtained from crude Al or alloys by employing these as the anode, in the form of a plate whose surface is increased by corrugation.

**Recovery of tin.** SIEMENS & HALSKE A.-G. Fr. 650,579, Mar. 8, 1928. In the electrolytic recovery of Sn from alk. lyes, the lye is treated before electrolysis with addnl. oxidizing agents until all the Sn is in the form of stannate, and a colloid such as gelatin is added. The oxidizing agent is introduced in a hollow perforated vessel.

**Electrical treatment of hydrocarbons.** SIEMENS & HALSKE A.-G. (Hans Becker, inventor). Ger. 474,740, Apr. 16, 1925. Addn. to 466,813. App. for treating hydrocarbons by the method of Ger. 466,813 (C. A. 23, 1577) is described.

**Electrolytic production of lead peroxide.** SIEMENS & HALSKE A.-G. Brit. 299,306, Oct. 22, 1927. A coating of Pb peroxide is deposited on an elec. conductor connected as anode from an alk. soln. of a Pb salt such as a soln. formed from  $PbO$  and  $NaOH$

to which is added an org. compd. of one of the classes: (1) compds. with hydroxy groups such as phenol, resorcinol, hydroquinone, pyrogallol, tannin, phloroglucine, glycerol, sugar, or fluorescein; (2) org. acids such as HOAc or succinic acid; or (3) C-N compds. such as dimethylglyoxime, alizarine-bordeaux, rhodanide and cyanides. A current d. of 1 amp. per sq. dm. is used.

**Measuring the concentration of electrolyte solutions.** I. G. FARBENIND. A.-G. (Hermann Wolff, inventor). Ger. 466,530, Jan. 9, 1926. In an app. for the continuous measurement of the concn. of an electrolyte soln., the soln. flows through a vessel in which are immersed (1) two electrodes connected to a source of a. c., and (2) a vessel contg. an electrolyte soln. of const. concn. and contg. also 2 electrodes in series with those in the larger vessel. The circuit includes also a variable resistance and a voltmeter; the arrangement is such that the tensions between each pair of electrodes can be measured and compared.

**Electrical purification of gases.** METALLGES. A.-G. Ger. 475,109, Sept. 18, 1926. The elec. sepn. of suspended particles from gases contg. O is conducted so as to avoid the formation of  $O_3$ . This may be done by arranging the discharge electrode in an atm. of N in a space sepd. from the pptg. space but with openings for the passage of the ions into the gas stream to be purified. For example, the discharge electrode may be enclosed in a porous or perforated casing through which N is led.

**Electric annealing furnace.** PAUL MENÉ. Fr. 650,197, Feb. 29, 1928. Construction of heating chamber.

**Electrode mounting for electric furnaces.** SOC. ELECTRO-METALLURGIQUE DE MONTRICHER. Brit. 299,414, Oct. 26, 1927. Structural details.

**Electrode mounting for electric furnaces.** SOC. ELECTRO-METALLURGIQUE DE MONTRICHER. Brit. 299,429, Oct. 26, 1927. Structural features.

**Electrically heated steam superheater.** SIEMENS-SCHUCKERTWERKE A.-G. Ger. 475,335, June 4, 1926.

**Temperature regulator for electric apparatus.** ALFRED DÄNIKER. Fr. 650,997, Mar. 19, 1928.

**Thermoelectric current controller suitable for protecting electric apparatus.** OTTO DREYER. U. S. 1,711,634, May 7.

**Electric contact points.** MUIRHEAD & Co., LTD., F. H. MUIRHEAD, F. S. HEURTELEY and J. V. FOLL. Brit. 299,593, Oct. 5, 1927. Points such as those of Pt are embedded in a soft metal such as Pb to prevent chattering.

**Electrical conductor.** HENRI ANDRÉ. Ger. 475,339, Aug. 18, 1927. An elec. conductive material with a high neg. temp. coeff. is prepd. by fusing Ag or a Ag salt with an excess of S or P and casting the product. The conductor may be used in a bath of fused S.

**Composition for coating electrical conductors.** JARED E. SMITH. U. S. 1,711,754, May 7. A compn. suitable for coating metal conductors in order to protect them from acids comprises petroleum residuum 99.5 and creosote 0.5%.

**Dielectric materials.** COMPAGNIE FRANÇAISE POUR L'EXPLOITATION DES PROCÉDÉS THOMSON-HOUSTON. Fr. 651,397, Mar. 13, 1928. A dielectric material such as  $PhNO_2$  is mixed with another dielec. material such as nitrotoluene, dinitrobenzene, or  $PhCl$  to lower the m. p. of the material and so improve its value for use at low temps. Impurities in  $PhNO_2$  such as water, acids or salts are removed by mixing with  $Al_2O_3$ , heating to  $100^\circ$  and distg. Dielec. materials in the fluid state may be purified by using them as electrolytes in an electrolytic cell.

**Large mercury-vapor rectifier with insulated cathode.** AKTIEN GESELLSCHAFT BROWN, BOVERI & CIE. Ger. 475,034, Feb. 20, 1923.

**Oil-cooling device for a mercury-vapor rectifier.** ALLGEMEINE ELEKTRICITÄTS-GES. (Gustav W. Müller, inventor). Ger. 470,101, July 14, 1923.

**Oil-cooling device for a mercury-vapor rectifier.** ALLGEMEINE ELEKTRICITÄTS-GES. (Gustav W. Müller, inventor). Ger. 471,484, Apr. 18, 1925. Addn. to 470,101.

**Expansion device for transformers or other electrical apparatus containing oil and inert gas.** LELAND H. HILL (to Westinghouse Elec. & Mfg. Co.). U. S. 1,712,765, May 14. Structural features.

**Tungsten filaments.** WILLIAM B. GERO (to Westinghouse Lamp Co.). U. S. 1,712,663, May 14. W filaments are straightened under tension at a white heat in H<sub>2</sub> wound under tension on a form without heating and then severed into individual lengths. An arrangement of app. is described.

**Metals and alloys.** TURE R. HAGLUND. Fr. 650,883, Mar. 15, 1928. In the prepn. of metals or alloys by reduction of oxides or ores in an elec. furnace, the starting materials are so chosen or addns. are made to the starting materials that a strongly

refractory slag contg. MgO and  $Al_2O_3$  and less than 15%  $SiO_2$  is obtained. If an Fe ore is treated which contains a large proportion of  $SiO_2$ , this may be partly reduced to Si, or magnesite and bauxite contg. little  $SiO_2$  may be added. The refractory slag may be used for making furnace hearths, etc.

## 5—PHOTOGRAPHY

C. E. K. MEES

**Toning of silver images by dye mordanting.** R. NAMIAS. *Il prog. fot.* 35, 73-8, 109-19, 145-51(1928).—The process recommended is that using  $Cu(CNS)_2$ . The formula is:  $CuSO_4$ , 20 g.; neutral Na citrate, 60 g.;  $AcOH$ , 40 cc.;  $H_2O$ , 1 l. After complete soln., 20 g. of  $NH_4CNS$  is added. For dyeing, basic dyes are used; those recommended are auramine, rhodamine, malachite green and methylene blue. For reduction and clearing of the whites, a weak soln. of neutral  $KMnO_4$  is recommended without acid, followed by bisulfite.

C. E. K. MEES

**A simple method for reducing the time of exposure of photographs, particularly x-ray photographs.** FRITZ EBERT. *Z. anorg. allgem. Chem.* 179, 279-80(1929).—By heating the plate holder to  $40^\circ$  it was found that the reaction velocity of the photographic process was increased to such an extent that 50-70% less exposure was required. Due to the reduction of exposure time, fogging was diminished.

A. J. K.

**Determination of the silver nuclei produced by the ripening of a photographic emulsion.** H. KIESER. *Z. Elektrochem.* 35, 51-3(1929).—Work on the photochem. equivalence law with respect to the Ag halide of the photographic emulsion is reviewed. Instead of the so-called original Ag proposed by Weigert and Lühr (*C. A.* 23, 1829, 2111) to account for the inefficiency of the above law, K. proposes that this hypothetical original Ag is actually  $Ag_2S$ . He prepd. plates coated with AgBr free from any medium such as gelatin to remove error caused by its presence. With such a prepn. he made tests analogous to those of the above experimenters and found in all cases that  $Ag_2S$  was obtained instead of Ag. AgBr in the presence of excess Ag ion forms  $Ag_2S_2O_8$ , which quickly decomposes, if Ag ion is present in large excess, to form  $Ag_2S$ . This would account for results obtained by Weigert and Lühr with a Valenta emulsion. Persulfate not only attacks the original Ag, but on account of insufficient washing also dissolves the photo-silver. Increase in original Ag by heat is explained by reduction by the medium. Original Ag is probably present but in such small quantities that no present quant. method is known for detg. it.

R. H. LAMBERT

**Primary process in the formation of the latent photographic image.** F. C. TOY AND G. B. HARRISON. *Nature* 123, 679-80(1929).—It is now generally supposed that the formation of the latent image involves the transference of a valency electron from the Br to the Ag by the absorption of light by AgBr, the Br being absorbed by substances present in the emulsion by a complicated chem. process. If pure AgBr is completely enclosed, so that Br cannot escape, an equil. will be set up between the transference and back-transference of the valency electrons, when the AgBr is illuminated. The presence of these temporary free electrons will account for the photo-conductivity effect. In testing for this effect it is necessary to use Ag electrodes and shield them from the light or disturbances will arise. A beam of light was sent through a thin layer of AgBr, fused between quartz plates, on to one half of a film moving behind a fixed slit. The photo-current was amplified about 100,000 times and fed to a string galvanometer, an image of the string being focused on the other half of the moving film. A time scale was registered on the film. Thus it was possible to compare the times of commencement of illumination and photo-current; it was found that the current started within 0.001 sec. of the illumination, and was built up fully in 0.03 sec. Since the galvanometer lag is as much as this, it is justifiable to assume that the effect starts instantaneously and reaches its final value in a time very much less than 0.3 sec. The photocond. effect is observable in the region of normal photographic illumination.

E. W. H. S.

**New field of application for desensitizers.** O. PAPESCH. *Phot. Korr.* 65, 73-4 (1929).—P. recommends the use of a desensitizer, preferably pinakryptol green, in the toning of slow papers, such as Bradux or Kodura, by the method of full exposure and restrained development. The white illumination, which is then admissible, enables the color of the image to be examd. and development arrested accordingly. Any residual stain from the pinakryptol green may be quickly removed by a bath of 1.5% red fuming  $HNO_3$ .

E. R. BULLOCK

**The influence upon light absorption and photochemical sensitivity of adsorbed ions.** H. FROMHERZ AND G. KARAGUNIS. *Z. physik Chem.*, Abt. B, 1, 346-61 (1928).—Absorption measurements were made on a gelatin AgBr emulsion spread on plate glass and soaked with AgClO<sub>4</sub> or KBr soln., thus giving a Ag- or Br- body, resp. Results correspond with those obtained with hydrosols, namely, an increased absorption of the Ag body toward the longer wave lengths as compared with the Br body. Analogous expts. with AgBr to which Th ions are adsorbed showed a similar effect but not so great as with Ag ions. The effects of other ions were also studied and the results were in agreement with those in which gelatin-free AgBr was used. E. P. WIGHTMAN

**Influence on the light absorption of the adsorption of silver and bromine ions to silver bromide hydrosols.** HANS FROMHERZ. *Z. physik Chem.*, Abt. B, 1, 324-45 (1928).—A method is described for the measurement of the relative degree of coagulation of AgBr hydrosols free of binding medium by means of the scattering of light. The method was used to det. the dependence of the degree of coagulation upon the presence of excess Ag or Br ions in the soln. The absorption spectrum of AgBr with adsorbed Br or Ag ions, the particles having the same size in each case, was measured and an increased absorption in the green and yellow was observed with the Ag body as compared with the Br body. This extension towards the longer wave lengths amounted to as much as 15-20  $\mu$ . The results confirm earlier observations according to which photochem. sensitivity of AgBr is increased by the adsorption of Ag ions.

E. P. WIGHTMAN  
**The manufacture of photographic paper.** JOSEPH ROSSMAN. U. S. Patent Office, Washington, D. C. *Paper Trade J.* 88, No. 7, 59-64 (1920).—A brief discussion of the difficulties encountered in the manuf. of photographic papers, with abstracts of U. S. patents. A. PAPINEAU-COUTURE

The chemist in the graphic industry (VNUK) 13.

DAVID, LUDWIG: **Photographisches Praktikum. Lehrbuch d. Photographie.** 6th ed., revised and enlarged. Halle: W. Knapp. 808 pp. M. 16; bound, M. 19.

**Handbuch d. Photographie. Band I. Teil 1.** W. NODDACK: **Photochemie.** ERICH LEHMANN: **Photographische Chemie.** 314 pp. Linen, M. 15. **Teil 2. WILLY NAUCK: Die Fabrikation d. photograph. Materialien.** ERICH LEHMANN: **Die Prüfung d. photograph. Materialien.** 282 pp. Linen, M. 12. Berlin: Union Zweigniederlassg.

GREBE, LEONHARD, HÜHL, ARTHUR AND WALL, EDUARD J.: **Handbuch der wissenschaftl. u. angewandten Photographie. Band VIII. Farbenphotographie.** Vienna. J. Springer. 248 pp. M. 24; bound, M. 26.80.

**Color photography.** LOUIS DUFAY. Fr. 651,196, Aug. 29, 1927. An emulsified reflecting, translucent, or transparent support for the reproduction, printing or multiplication of transparent color proofs obtained by the process of juxtaposed green, violet and orange screens, comprises a screen incapable of direct selection of natural colors, but capable, on the other hand, of pos. synthesis, being made up of juxtaposed elements of simple or primary colors, *i. e.*, yellows, blues and reds. Cf. C. A. 2, 2892.

**Color photography.** JOHANNES HERZOG & Co. Ger. 470,975, Feb. 23, 1928. Addn. to 466,327 (C. A. 23, 1071). In the production of colored prints by the oxidation of leuco dyes described in the prior patent, the treatment with leuco dye is preceded by the oxidation of the Ag or other metal salt forming the print by such oxidizing agents as H<sub>2</sub>O<sub>2</sub>, per-salts, Mn compds. or V salts.

**Color photography.** RUDOLF RUTH. Fr. 650,496, Mar. 6, 1928. Color images which may be examd. directly on an opaque support are obtained by applying to a transparent support a detachable layer of color screens formed, *e. g.*, of a layer of gelatin colored in red, green and blue. On this layer a sensitive emulsion of AgBr is spread. The exposure or reproduction of an image is made through the support on the negative thus prepd. During development a developer is used, which sets free a large proportion of oxidation products hardening the gelatin, such as pyrocatechol. The reduced Ag is dissolved and the Ag salt remaining is developed in full light as for autochrome plates, but in the 2nd development a developer giving oxidation products is not used. A sheet of paper to serve as a provisional support is pressed onto this plate and the layer of colored screens is treated with warm water to eliminate all unhardened parts. The process may be combined with that known as "Ozobrome."

**Color photographs.** WILLIAM V. D. KELLEY (to Max B. DuPont Vitalcolor

Corp.). U. S. 1,712,439, May 7. In forming differently colored sep. images in a colloid carrier, a bleached dye absorbent image and a sep. reduced Ag image are formed in the carrier; the former is dyed and the latter colored a different color. The process is suitable for making colored motion picture films. Cf. *C. A.* 22, 2891.

**Photographic intensifying process.** OTTO MUCK. Ger. 475,459, Dec. 8, 1927. A plurality of points on a feeble image act simultaneously or successively on photoelec. cells, the currents from which are amplified to an equal degree, caused to act on sources of light, and finally reconverted so that each point on the strengthened image corresponds to a point on the original image.

**Photographic films and papers.** VICTOR PLANCHON. Fr. 650,143, Aug. 10, 1927. The sensitive layer is obtained by flowing a single soln. contg. both the gelatin and Fe salts, the compn. in Fe salts being such that alteration of the gelatin is slow. An example is given.

**Photographic films and paper.** SOC. INDUSTRIELLE D'APPLICATIONS PHOTOGRAPHIQUES (Soc. anon.). Fr. 650,123, Aug. 10, 1927. A machine for the continuous development of photographic films and papers by  $\text{NH}_3$  gas is described; in this app. the films, etc., are caused to travel by means of endless bands over the curved perforated top of a chamber contg.  $\text{NH}_3$  gas. Cf. *C. A.* 23, 2670.

**Desensitizing photographic films.** I. G. FARBERNIND. A.-G. Fr. 650,786, Mar. 12, 1928. Photographic films having AgBr emulsions are desensitized by means of an aminophenylphenazonium salt having at least 2 amino groups situated in a C nucleus belonging to an azine complex. In examples, a film or plate is placed in an aq. soln. (about 1:5000) of 1,3-diaminophenylphenazonium chloride (I) for 1–2 mins. and then developed in yellow or candle light. A developer such as "Rodinal" or glycine is mixed with an aq. soln. of I; a plate or film dipped for 1 min. in this soln. may be developed by yellow or candle light. I may be replaced by 1,3-diamino-7-aminophenylphenazonium chloride, 2,3-diaminophenylphenazonium nitrate, 1,3-diamino-*o*-(or *p*)-tolylphenazonium chloride, 1,3-diamino-6-(or 7)-chlorophenylphenazonium chloride, or the corresponding *o*-(or *p*)-hydroxyalkylphenyl derivs. Cf. *C. A.* 23, 2381.

**Developing and other liquid treatments of photographic negatives and prints.** ÉTABLISSEMENTS B. BELIN. Brit. 299,466, Oct. 28, 1927. Liquids such as those used for developing, fixing, washing or drying are applied to negatives or prints by spraying so that this action assists in the penetration of the liquid, and the liquids may be used at a temp. somewhat above normal. Washing is not required between developing and fixing. Rapid drying may be effected by use of an alk. carbonate soln., which is wiped off with scrapers or felt after application.

**Toning blueprints green.** RUDOLF FRITSCH. U. S. 1,712,428, May 7. Blueprint images composed of ferrous ferricyanide are subjected to a soln. of a U salt such as U nitrate until the blue surface of the prints is changed to a green color; the prints are then washed with water.

**Half tones.** HERBERT H. IVES (to Bell Telephone Laboratories). U. S. 1,711,684, May 7. In order to produce a half-tone negative suitable for printing on metal to produce a typographic printing plate of correct tone rendering characteristics, a variable density photographic negative is first made from the object; from this there is made a structured positive by exposure through a screen, and from this positive there is formed a negative by reproducing its structure complementary to the object characteristic.

## 6—INORGANIC CHEMISTRY

A. R. MIDDLETON

**Sulfur nitride.** II. S. A. VOZNESENSKII. *J. Russ. Phys.-Chem. Soc.* 60, 1037–44 (1928); cf. *C. A.* 22, 1113.—The color reactions given by  $\text{N}_4\text{S}_4$  and by thiotriethiazyl chloride,  $\text{N}_3\text{S}_4\text{Cl}$ , in various solvents and in acid and alk. solns. are contrasted. The latter substance reacts with HCl according to the equation:  $2\text{N}_3\text{S}_4\text{Cl} + 12\text{H}_2\text{O} + 4\text{HCl} = 2\text{H}_4\text{S}_6\text{O}_6 + 6\text{NH}_4\text{Cl} + 2\text{S}$ ; with water:  $2\text{N}_3\text{S}_4\text{Cl} + 12\text{H}_2\text{O} \longrightarrow 2(\text{NH}_4)_2\text{S}_6\text{O}_6 + 2\text{NH}_4\text{Cl} + 2\text{S}$ . B. C. A.

**The nomenclature of inorganic compounds.** ANON. *Gazz. chim. ital.* 58, 883–91 (1928).—The latest recommendations of the International Union of Pure and Applied Chemistry are given. C. C. DAVIS

**Some criticisms of the current teaching of inorganic chemistry.** ROBERT DUBOIS. *J. Chem. Education* 6, 906–13 (1929). E. H.

**Univalent iron, cobalt and nickel, and nitrososulfo salts.** Reply to W. Manchot.

I. CAMBI. Istituto Chimico, Reale Univ. Milano. *Gazz. chim. ital.* 59, 56-9(1929).—Comments on an article of Manchot (*C. A.* 23, 1073). AgNO does not arise from reduction of AgNO<sub>3</sub> because it is also obtained when other Ag salts are used; in fact, AgClO<sub>4</sub> gives the highest yield of AgNO. The reaction is therefore of great significance in its refutation of the conclusions of Manchot. The spectrographic measurements of M. and Linck are not precise and the indexes of extinction of Fe nitrososulfide are close to those of other complex ferric salts. The intermediate formation of HNO<sub>2</sub> and the reduction suggested by M. by the reaction:  $\text{Fe}^{++} + \text{NO} + \text{OH}^- \longrightarrow \text{Fe}^+ + \text{HNO}_2$  are absurd, for under the conditions, HNO<sub>2</sub> is an oxidizing agent, and the Roussin salts form in the presence of an excess of FeSO<sub>4</sub> from FeS and alk. nitrite. Moreover, the appearance of HNO<sub>2</sub> and of nitrite in the synthesis of other sulfo salts does not necessitate reduction of the metal, for this would exclude the reaction:  $2\text{NO} + \text{H}_2\text{O} \longrightarrow \text{HNO} + \text{HNO}_2$ , which is probably the intermediate step in the transformation of NO to nitrite and N<sub>2</sub>O by the action of alkalis. The synthesis of nitrososulfo ethers as described by M. and Gall (*cf. C. A.* 22, 2892) can be explained by the reaction:  $2\text{NO} + (\text{RS})^- \longrightarrow (\text{NO})^- + \text{RS}\cdot\text{NO}$ , in which NO acts like a halogen. The formation of the disulfide may be explained by the intermediate formation of the free radical RS $\cdot$ , thus:  $(\text{RS})_2\text{Ni} + \text{NO} \longrightarrow \text{RS}\cdot\text{NiNO} + \text{RS}\cdot$ , the RS $\cdot$  then participating in 2 reactions:  $2\text{RS}\cdot \longrightarrow \text{RS}\cdot\text{SR}$  and  $\text{RS}\cdot + \text{NO} \longrightarrow \text{RS}\cdot\text{NO}$ . These reactions do not affect the valence of the metal. The explanation of M. and G. rests on a fundamentally erroneous premise, in that nitrosyl mercaptides are not analogous to HNO<sub>2</sub> with respect to oxidation, for they decompose to NO and the disulfide and autooxidize to hyponitrites and disulfides, *i. e.*, they are reduction products of HNO<sub>2</sub> and are analogous to NO (*cf. Lecher and Siefkern, C. A.* 20, 2976). It is extremely unlikely that, as maintained by M., there can be assocn. between a metal in a reduced and highly oxidizable state, and NO in a state corresponding to halogens. C. C. DAVIS

Constitution of hydroxides and of hydrates. III. Octahydrated strontium hydroxide. G. NATTA. Reale Politecnico, Milano. *Gazz. chim. ital.* 58, 870-82(1928); *cf. C. A.* 23, 350, 1361.—Though many compds. contg. H<sub>2</sub>O of crystn. have been examd. by x-rays, the position of this H<sub>2</sub>O in the lattice and its dimensions have not been detd. directly heretofore. Sn(OH)<sub>2</sub>·8H<sub>2</sub>O was particularly suitable and interesting for the expts., for it contains both OH groups and H<sub>2</sub>O of crystn., has a high degree of symmetry and a small elementary cell. The position of the H<sub>2</sub>O of crystn. with respect to the positions and dimensions of the other atoms is of interest also in studying the relative stability of hydrates, the dimensions of coördinating ions, the mode of coördination of various atoms in the lattice, and the vols. of the elementary cells. Knowledge of the exact lattice dimensions of hydrated compds. can furnish data for the direct measurement of the mol. vol. of H<sub>2</sub>O of crystn., a vol. which numerous experimenters have tried to det. from the different mol. vols. of the hydrated and anhyd. compds. This method, besides being based on data of doubtful precision (in that the exptl. d. is much lower than the actual d.), does not take into account the fact that by introduction of H<sub>2</sub>O into the lattice, new structures are often formed, the mol. vols. of which may be far different from the sum of the mol. vols. of the anhyd. salt and that of the H<sub>2</sub>O of crystn. Sr(OH)<sub>2</sub>·8H<sub>2</sub>O crystallizes in the tetragonal system, and has an elementary cell with *a* = 6.41 Å. U., *c* = 5.807 Å. U., and a vol. of  $238 \times 10^{-24}$  cc., contg. 1 mol. of Sr(OH)<sub>2</sub>·8H<sub>2</sub>O. The calcd. d. is 1.85. A discussion of the possible distribution of the atoms in the lattice leads to the conclusion that the structure may be defined by the following coördinates: bivalent Sr ion (000); O of the OH group ( $\frac{1}{2}$ , 00); (0 $\frac{1}{2}$ , 0); O of the H<sub>2</sub>O of crystn. (*u u v*) (*-u -u v*) (*-u -u v*) (*-u -u v*) (*u -u v*) (*u -u v*) (*-u -u v*) (*-u -u v*). The values of the parameters, which define the positions of the O of the H<sub>2</sub>O of crystn., are approx. 0.25 for *v* and 0.29-0.30 for *u*. C. C. DAVIS

Observations on the rare earths. XXXI. Ionic migration and magnetism in the separation of the rare earths. PIERCE W. SELWOOD WITH B. S. HOPKINS. *Trans. Am. Electrochem. Soc.* 55, (preprint), 13 pp.(1929).—Expts. were conducted to det. the applicability of the ionic migration method to certain problems in the concn. of the rare earths. It does not compare favorably with the older methods. A review is given of the factors underlying ionic mobility. Details are given in the second part of the paper of attempts made to use the magnetic properties of the rare earths for their sepn. As yet no sepn. has been detected, although the method seems theoretically sound. XXXII. Fractional hydrolysis of rare earths by electrolysis. H. C. KREMERS AND L. L. QUILL. *Ibid* 5 pp.—Neutral solns. of the rare earths give hydroxides at the cathode when electrolyzed. By stirring the cathode portion, a fractional pptn. may be effected. The order of pptn. will follow the order of increasing basicities of the rare earths. The hydroxides produced are granular and easily filtered. The sepn. of Yt from Ho and

Er and the relation of Yt to the Ce group earths were especially studied. From the standpoint of time, convenience and quantity of material to be fractionated, this method is superior to most ordinary fractionation methods depending upon relative basicities. Efficiencies are also practically equal. C. G. F.

The separation of columbium and tantalum by electrolytic hydrolysis. L. F. YNTEMA. *Trans. Am. Electrochem. Soc.* 55 (preprint), No. 8, 3 pp. (1929).—An incomplete sepn. of Cb and Ta is effected by making the soln. of the mixed salts the electrolyte in the anode compartment of an electrolytic cell. The sepn. depends on the pptn. of the insol. columbic and tantalic acids at the diff. H-ion concns. produced during the course of the electrolysis. W. H. BOYNTON

The action of potassium ferrocyanide upon silver and various difficultly soluble silver salts. ERNST BEUTEL and ARTUR KUTZLNIGG. Hochschule f. Welthandel, Wien. *Monatsh.* 51, 369–80 (1929).—The soln. of Ag in boiling solns. of  $K_4Fe(CN)_6$  is due to the decompn. of the latter in the presence of air to give KCN and  $Fe(OH)_3$ . This fact also accounts for the soly. of AgCl, AgBr, AgCN,  $Ag_2Fe(CN)_6$ ,  $Ag_2O$ ,  $Ag_2CO_3$  and  $Ag_2CrO_4$  in alkali ferrocyanide solns. These Ag compds. are also sol. in cold ferrocyanide solns., resulting in the formation of colloidal  $Fe(OH)_3$ . The soly. of  $Ag_2Fe(CN)_6$  in  $H_2O$  lies between that of AgCl and that of AgBr. L. F. AUDRIETH

The action of ozone upon alkali azides. I. Pernitrous acid. KARL GLEU and ERNST ROELL. *Z. anorg. allgem. Chem.* 179, 233–66 (1929).—Purely chemical methods for the oxidation of  $HN_3$  in acid and in neutral soln. are reviewed. The authors have studied the action of ozone upon  $NaN_3$  in neutral and in alk. soln. Ozonized oxygen ( $10\% O_3$ ) passed into  $N NaN_3$  solns. gave a yellow coloration that changed to an orange-red after several hours. Further ozonization caused gradual fading and eventual decoloration. The final colorless soln. was found to be strongly alk., contained nitrites and nitrates, but no azide. The orange-red solns. (A) lost their color upon standing. Addn. of alkali increased the stability of the color, whereas heating or acidification caused its destruction. No yellow compd. could be pptd. from soln. by the addn. of various org. solvents. Ozone had no effect upon  $NaN_3$  dissolved in liquid  $NH_3$ . Heating of A caused evolution of  $O_2$ ,  $N_2$  and  $N_2O$ , the latter two in the vol. ratio, 1:1. Addn. of alkali decreased the relative amts. of  $N_2$  and  $N_2O$  evolved. Solns. ozonized past the stage of max. color intensity gave only  $O_2$  upon heating. Treatment of A with  $N_2H_4$ , HCHO, alk. solns. of stannous salts, hyposulfites,  $Na_3AsO_3$  and  $NaHCO_3$  caused immediate disappearance of the yellow color. The oxidizing power of A as detd. by means of  $Na_3AsO_3$  exceeds by 10% that required by the amt. of  $O_2$  evolved upon heating. Titration of A with standard HCHO solns. gave only  $1/2$  of the  $O_2$  required. The remainder was found to have oxidized an equiv. quantity of  $NaNO_2$  to  $NaNO_3$ . Alk. solns. of  $KMnO_4$  were reduced to green manganate. The  $KMnO_4$  used was found to be equiv. to the amt. of  $Na_3AsO_3$  and  $1/2$  HCHO employed.  $H_2O_2$  was shown to be absent, but the yellow compd. is believed to be an acid deriv. of  $H_2O_2$  in the form of the Na salt, probably pernitrous acid formed by decompn. of an ozonide of  $HN_3$ .  $HN_3 + O_3 = .HN_3(O_3) = HO-O-N=O + N_2$ . The non-formation of pernitrous acid by ozonization of other compds. contg. the imide group is regarded as evidence against the possible contention that the reaction involves decompn. of  $HN_3$  with the formation of the imide residue,  $HN$ , followed by subsequent addn. of  $O_3$ . Analytical methods are discussed in detail. Nitrites were detd. gas-volumetrically with aminosulfonic acid. In the presence of azides a measured amt. of standard  $H_2SO_4$  was added to the soln., the excess of acid titrated, and the amt. of  $HNO_2$  used up by the azide calcd. L. F. A.

Action of silica and alumina on sodium sulfate. GERMAINE MARCHAL. *Compt. rend.* 188, 258–60 (1929); cf. C. A. 18, 509.—The decompn. temp. of  $Na_2SO_4$  is lowered by the addn. of equimol. amts. of silica and alumina. When heated at  $1300^\circ$  the loss of wt. of the  $Na_2SO_4$  in the  $Na_2SO_4-SiO_2$  mixt. was 14.14% in 1 hr., and 24.2% in 3 hrs. In the  $Na_2SO_4-Al_2O_3$  mixt. the loss was 22.03% in 1 hr. and 31.29% in 3 hrs. The pure  $Na_2SO_4$  lost 0.87% in 1 hr. and 4.23% in 4 hrs. AMY LEVESCONTE

Action of silica, alumina and kaolin on barium sulfate. GERMAINE MARCHAL. *Compt. rend.* 188, 399–402 (1929); cf. preceding abstract and C. A. 20, 690.— $BaSO_4$ , when mixed with silica, alumina, or kaolin, is more than half decomposed when heated 4 or 5 hrs. at  $1300^\circ$ . The pure  $BaSO_4$  does not decompose at this temp. The action is rapid at first, slowing down later. The results indicate that  $BaSO_4$  may be substituted for  $BaCO_3$  in the glass and sugar industries. AMY LEVESCONTE

The nitrites. I. Nitrites of nickel and cobalt; pyridinates. L. LE BOUCHER. *Anales soc. españ. fis. quim.* 28, 145–56 (1929).—A new method of obtaining nitrites of bivalent heavy metals combined with pyridine consists in pptg. at  $0^\circ$  an aq. soln. of a metal salt by pyridine and  $NaNO_2$ . This is possible with Ni, Co, Fe, Mn, Cu, etc.

The ppt. contains the metal ion and the  $\text{NO}_2$  ion in the relation  $\text{M}^{++}:(\text{NO}_2)_2$ , combined with variable amts. of  $\text{H}_2\text{O}$  and pyridine. When the compds. are stored in a dry atm. in the presence of pyridine, all  $\text{H}_2\text{O}$  is replaced, giving a compd.  $\text{M}(\text{NO}_2)_n\text{Py}$ ,  $n$  being usually 6. From this compd. others contg. less pyridine can be obtained by storing *in vacuo* over  $\text{H}_2\text{SO}_4$ .  $\text{Ni}(\text{NO}_2)_2\cdot 6\text{Py}$  is a deep blue,  $\text{Ni}(\text{NO}_2)_2\cdot 4\text{Py}$ , a clear blue,  $\text{Co}(\text{NO}_2)_2\cdot 6\text{Py}$ , a red,  $\text{Co}(\text{NO}_2)_2\cdot 3\text{Py}$ , a rose-violet,  $\text{Co}(\text{NO}_2)_2\cdot 2\text{Py}$ , a deep red. Pyridine can be replaced by  $\text{NH}_3$ . The mol. vols. of the new compds. have been detd.

E. M. SYMMES

**The molybdates.** V. GÓMEZ ARANDA. *Anales soc. españ. fis. quim.* 28, 165-8 (1929); cf. *C. A.* 23, 2119.—Molybdates of Sr, Ba and Pb, prepd. by fusion, were analyzed; the  $\text{MoO}_3$  contents were found to be low. The ds. were 4.6624, 4.9747 and 6.9208, resp., not agreeing well with the literature.

E. M. SYMMES

**The systems potassium chloride-ferric chloride-water and aluminum chloride-ferric chloride-water between 0° and 60°.** G. MALQUORI. Istituto Chimico, Reale Univ. Roma. *Gazz. chim. ital.* 58, 891-8(1928).—Because Fe is present in the reaction liquor from the attack of leucite by HCl in the Blanc process (cf. Blanc, *C. A.* 19, 1616), it is of interest to det. whether and to what point this Fe can be held in soln. while the K and Al salts are pptd. In the present paper, the isotherms of the system  $\text{KCl-FeCl}_3\cdot\text{H}_2\text{O}$  at 0°, 25°, 35° and 60°, the isotherm of  $\text{AlCl}_3\text{-FeCl}_3\text{-H}_2\text{O}$  at 0°, and the 2 branches of the isotherms at 40° and 60° in which  $\text{AlCl}_3\cdot 6\text{H}_2\text{O}$  is the solid in excess, are given. These data are necessary in a study of the system:  $\text{HCl-KCl-AlCl}_3\text{-FeCl}_3\text{-H}_2\text{O}$  (cf. *C. A.* 21, 2229). The methods were the same as those used heretofore in similar expts. The results are recorded in tables and triangular diagrams. Hinrichsen and Sachsels have described the system  $\text{FeCl}_3\text{-KCl-H}_2\text{O}$  at 21° (cf. *Z. physik. Chem.* 50, 81(1905)), but contrary to their results, it was found that at 25°, 35° and 60° along the isotherms from satd. solns. of KCl to those of  $\text{KCl} + \text{FeCl}_3\cdot 2\text{KCl}\cdot\text{H}_2\text{O}$ , the solid in excess is always pure KCl; in fact, satd. solns. of  $\text{KCl} + \text{FeCl}_3\cdot 2\text{KCl}\cdot\text{H}_2\text{O}$  sepd. from the solid KCl and placed in contact with KCl do not change in compn. At 0° mixed crystals are possible, but it is not possible to obtain reliable analyses because of the small quantity of Fe and because of the difficulty of sepg. the mother liquors completely. The double salt  $\text{FeCl}_3\cdot 2\text{KCl}\cdot\text{H}_2\text{O}$  is stable at all the temps. studied, and contrary to Walden (cf. *Z. anorg. allgem. Chem.* 7, 331(1894)) it seps. only from solns. with a high  $\text{FeCl}_3$  content. The soly. relations of the system  $\text{AlCl}_3\text{-FeCl}_3\text{-H}_2\text{O}$  are simpler, in that only 2 solids are present at 0°, viz.,  $\text{AlCl}_3\cdot 6\text{H}_2\text{O}$  and  $\text{FeCl}_3\cdot 6\text{H}_2\text{O}$ . At 40° and at 60°, solns. contg. up to 45 and 38.9%, resp., of  $\text{FeCl}_3$  are in equil. with solid  $\text{AlCl}_3\cdot 6\text{H}_2\text{O}$  alone.

C. C. DAVIS

**The complex oxalates of scandium.** JAN ŠTĚRBA-BÖHM AND STANISLAV ŠKRAMOVSÝ. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 211-5(1928); cf. *C. A.* 23, 2698.—Salts were prepd. derived from the following acids:  $\text{HSc}(\text{C}_2\text{O}_4)_2$ ,  $\text{H}_2\text{Sc}(\text{C}_2\text{O}_4)_3$ ,  $\text{H}_3\text{Sc}(\text{C}_2\text{O}_4)_4$ , corresponding to the previously described acids  $\text{HScF}_6$ ,  $\text{H}_2\text{ScF}_6$ ,  $\text{H}_3\text{ScF}_6$ . The following salts were prepd.:  $\text{NH}_4\text{Sc}(\text{C}_2\text{O}_4)_2\cdot 2\text{H}_2\text{O}$ ,  $\text{KSc}(\text{C}_2\text{O}_4)_2\cdot 2\text{H}_2\text{O}$ ,  $\text{NaSc}(\text{C}_2\text{O}_4)_2\cdot 3\text{H}_2\text{O}$ ,  $\text{Na}_2\text{Sc}_2(\text{C}_2\text{O}_4)_3\cdot 9\text{H}_2\text{O}$ ,  $\text{K}_2\text{Sc}(\text{C}_2\text{O}_4)_3\cdot 4\text{H}_2\text{O}$ ,  $\text{Na}_2\text{Sc}(\text{C}_2\text{O}_4)_3\cdot 6\text{H}_2\text{O}$ . The correct formula for the oxalate is  $\text{Sc}_2(\text{C}_2\text{O}_4)_3\cdot 6\text{H}_2\text{O}$  instead of  $\text{Sc}_2(\text{C}_2\text{O}_4)_3\cdot 5\text{H}_2\text{O}$  as was reported by others.

WILLIAM J. HUSA

**Chromatocobaltammines. II. Dichromatotetramminecobaltates and the maximum coordination number of cobalt.** SAMUEL H. C. BRIGGS. *J. Chem. Soc.* 1929, 685-90; cf. *C. A.* 13, 2822.—A series of compds. is described in which the chromate radical forms part of a complex anion. These dichromo-tetrammine-cobaltates are obtained when a soln. of a di-aquo-tetrammine cobaltic salt is added to an excess of a concd. soln. of an alkali chromate, and the resulting soln. kept for several days at ordinary temp. Two cryst. forms have been prepd., green and brown. The presence of dichromate in the soln. appears to favor the production of the brown form. Li, Na, K and Mg salts were prepd. Evidence is adduced to show that in the green Mg form, Co has a coordination no. of 8.

LOUIS WALDBAUER

**Carbon disulfideselenide.** HENRY V. A. BRISCOE, JOHN B. PEEL AND PERCY L. ROBINSON. *J. Chem. Soc.* 1929, 56-60.—In attempting to prep.  $\text{CS}_2$  by passing  $\text{CS}_2$  over heated  $\text{FeSe}$ , a partial replacement occurred, giving  $\text{CSSe}$ , which is a new method for prep. the compd. Its phys. properties and some of its chem. reactions have been studied. It is similarly constituted to  $\text{CS}_2$  but is much less stable. Attempts to prep. the analogs of the thiocarbonates failed, but compds. of  $\text{CSSe}$  with phenylhydrazine and  $\text{C}_6\text{H}_5\text{NH}_2$  have been made.  $\text{CSSe}$  and  $\text{NH}_3$  under certain conditions yield compds., which appear to be highly polymerized and difficult to characterize.

L. L. QUILL

**Sulfoaluminates of calcium.** WILLIAM LERCH, F. W. ASHTON AND R. H. BOGUE. *Bur. Standards J. Research* 2, 715-31(1929).— $3\text{CaO}\cdot\text{Al}_2\text{O}_3\cdot 3\text{CaSO}_4\cdot 31\text{H}_2\text{O}$  is most satisfac-

torily prepd. by interaction of solns. of  $\text{CaSO}_4$  and Ca aluminate, preferably with added  $\text{Ca}(\text{OH})_2$ . The long needle-like hexagonal crystals have refractive indices  $n_D 1.464 \pm 0.002$ ,  $n_D 1.458 \pm 0.002$ ; they are uniaxial negative and show neg. elongation; they have a  $d_{20} 1.48$ . In the presence of dil. solns. of  $\text{CaSO}_4$ , ppts. have been obtained, which indicate an equil. mixt. of  $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot 3\text{CaSO}_4 \cdot \text{aq}$  and  $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{aq}$ . As the concn. of the  $\text{CaSO}_4$  increases, the amt. of the aluminate decreases and eventually disappears. The existence of a new Ca sulfoaluminate  $3\text{CaO} \cdot \text{Al}_2\text{O}_3 \cdot \text{CaSO}_4 \cdot 12\text{H}_2\text{O}$  has been demonstrated. The indices of refraction are  $n_D 1.504 \pm 0.002$ ,  $n_D 1.488 \pm 0.002$ . Its crystal habit is platy instead of acicular and the character of elongation is positive; its  $d_{20}$  is 1.95. The compd. is unstable, and under regular conditions, encountered in concrete, it is converted into the more stable form with the higher  $\text{CaSO}_4$  content. The transformation is retarded by increasing OH-ion concn. In the presence of only a slight excess of sol. carbonates or Mg salts the sulfoaluminates will be destroyed. When both sulfate and chloride solns. are present, the high Ca sulfoaluminate will be formed to the exclusion of Ca chloroaluminate, if there is sufficient  $\text{CaSO}_4$  present.

E. SCHOTTE

**Oxidation of halogen acids by sulfuric acid.** KSENIA PROSKOURIAKOFF. *J. Phys. Chem.* 33, 717-9(1929).—The temps. at which various strengths of  $\text{H}_2\text{SO}_4$  (25-50% and 60-90%, resp.) oxidize HI and HBr are given.

## 7—ANALYTICAL CHEMISTRY

W. T. HALL

**A system of general reagents for courses in qualitative analysis.** LOUIS J. COURT-MAN. College of the City of New York. *J. Chem. Education* 6, 686-96(1929).—To save trips to reagent shelves and to make each student responsible for his own reagents, students are given small portions of about 70 different substances which they are likely to use in making qual. tests.

W. T. H.

**Applications of ceric sulfate in volumetric analysis. VI. Oxidation of hydrogen peroxide by ceric sulfate. Indirect determination of lead.** N. HOWELL FURMAN AND JOHN H. WALLACE, JR. Princeton Univ. *J. Am. Chem. Soc.* 51, 1449-52(1929); cf. C. A. 23, 2390.—Data are given showing that the direct potentiometric titration of  $\text{H}_2\text{O}_2$  with  $\text{Ce}(\text{SO}_4)_2$  soln. is accurate in solns. which are moderately acid in  $\text{HCl}$ ,  $\text{H}_2\text{SO}_4$ ,  $\text{HNO}_3$ , or  $\text{AcOH}$ . The titration in the reverse direction is also accurate in the presence of  $\text{H}_2\text{SO}_4$  or  $\text{HNO}_3$ . Like  $\text{MnO}_2$ ,  $\text{PbO}_2$  reacts with  $\text{H}_2\text{O}_2$  in the presence of  $\text{HNO}_3$ . By measuring the quantity of  $\text{H}_2\text{O}_2$  used and titrating the excess with  $\text{Ce}(\text{SO}_4)_2$ , the quantity of  $\text{PbO}_2$  can be detd. satisfactorily with 0.18-0.25 g. of material.

W. T. HALL

**Studies in iodometry. III. Copper as a standard in iodometry.** STEPHEN POPOFF, MARGARET JONES, CARL RUCKER AND W. W. BECKER. State Univ. Iowa. *J. Am. Chem. Soc.* 51, 1299-1306(1929); cf. C. A. 19, 2920-1.—Under proper conditions, the reaction between Cu and KI can be used for the accurate standardization of  $\text{Na}_2\text{S}_2\text{O}_3$  solns. The reaction should proceed in a soln. as nearly neutral as possible in the presence of 4% of KI and in the absence of salts. The presence of  $\text{H}_2\text{SO}_4$  sufficient to make the soln. 0.2 N or of  $\text{AcOH}$  enough to make the soln. 0.4 N serves to decrease the  $\text{I}_2$  liberated by 0.2% and 0.08%, resp. In the electrodeposition of Cu, losses will ensue unless care is taken in removing the electrode. **IV. Potassium permanganate as a standard in iodometry.** STEPHEN POPOFF AND ADOLF H. KUNZ. *Ibid* 1307-11.—In the  $\text{Na}_2\text{S}_2\text{O}_3$ - $\text{I}_2$  reaction there is no appreciable oxidation of the  $\text{I}^-$  ion by the air of the lab. if the soln. contains 6% of KI and is 0.2 N in  $\text{H}_2\text{SO}_4$ , provided the titrations are made in the dark.

W. T. HALL

**Avoiding an over-titration.** G. BRUHNS. *Chem.-Ztg.* 53, 248(1929).—The tricks of saving out a part of the soln. and titrating in porcelain dishes while stirring may be old-fashioned but are still useful.

W. T. H.

**Microtitration of iodides, even in the presence of large quantities of nitrite.** J. F. RERRH. *Rec. trav. chim.* 48, 386-90(1929); cf. C. A. 23, 2675.—Nitrites cause low results in the microchem. detn. of iodides by the Winkler principle. This difficulty is best overcome by the use of  $\text{NaN}_3$  (1.7 mg. for 1 mg. of  $\text{NaNO}_2$ ). To 1 cc. of the soln. to be titrated, contained in a 25-cc. Erlenmeyer flask, add an excess of 5%  $\text{NaN}_3$  soln. and make acid to methyl-orange paper with 2 *N*  $\text{H}_2\text{SO}_4$ . Boil vigorously and when the odor of  $\text{NH}_3$  is no longer evident, add a little more to make sure that an excess is used. Make acid again and boil again. Finally add 2 drops of 0.5 *N*  $\text{H}_2\text{SO}_4$  and 3 drops of Br aq., boil off excess Br, add KI and starch and titrate with  $\text{Na}_2\text{S}_2\text{O}_3$ . The detn. depends upon the formation of iodate and its reduction by KI. The use of Br is preferable to Cl because it is easier to make sure that the excess is removed. W. T. H.

**Note on gas analysis.** JAMES T. DONNELLY, C. HAMILTON FOOT AND J. REILLY. Univ. College at Cork. *Sci. Proc. Roy. Dublin Soc.* 19, 165-72(1929).—A photograph and diagrammatic sketch are shown of the Bone and Wheeler app. with certain modifications not previously described. The gas sample is collected in a test tube, introduced into a bell tube under Hg, the gas pressure read and then the gas is brought into contact with various reagents under the bell and the pressure detd. at const. vol. after each absorption. A stopcock with Hg seal is shown and a specially designed CuO furnace for detn. of  $\text{H}_2$ . Particular attention was paid to the elimination of danger from Hg poisoning in the design of the app., of the lab. shelves and even of the lab. flooring. W. T. H.

**Indicators. XII. Azo-indicators.** A. THIEL AND O. PETER. *Z. anorg. allgem. Chem.* 173, 169-98(1928).—Methyl orange exists as a yellow purely azo form and as a red, practically completely quinonoid, form. The electrochem. and color equilibria coincide almost exactly, the indicator thus satisfying the modified Ostwald theory of indicators. The double change is limited to the *p*-aminoazobenzene-*o*-carboxylic acid derivs. Considerable evidence has been obtained for the hypothesis of closed ring formation. A no. of relationships exist between the indicator properties of a substance and its constitution. The half-way stages of all sulfonic and *m*'- and *p*'-carboxylic acids are practically identical and are in accord with those of the free bases having similar amino complexes. The *o*'-carboxylic acids are bivalent indicators, of which the half stage of the first change (basic) lies below that of substances of the first group having the same amino complexes. The color change of the yellow forms of the acidic indicators increases in the order *o*'-, *m*'-, *p*'-, while for the red forms the order is *o*'-, *m*'-, *p*'- for the sulfonic acids and *m*'-, *p*'-, *o*'- for the carboxylic acids, successive increases being produced in all cases by substitution in the amino group in the order: unsubstituted, dimethyl and monophenyl, diethyl for the yellow forms, and unsubstituted, diethyl, dimethyl, monophenyl for the red forms. The depth of color of all the indicators increases by substitution in the amino-group in the order: unsubstituted, monophenyl, dimethyl, diethyl for the yellow forms and unsubstituted, dimethyl or diethyl, monophenyl for the red forms. B. C. A.

**Barium sulfate as an indicator of the effectiveness of sulfuric acid in desiccators.** G. БОРН. *Chem.-Ztg.* 53, 323(1929).—Add 18 g. of  $\text{BaSO}_4$  to 1 l. of concd.  $\text{H}_2\text{SO}_4$ . A ppt. of  $\text{BaSO}_4$  will appear only when sufficient  $\text{H}_2\text{O}$  has been absorbed to render the acid unfit for further use in desiccators. E. M. SYMMES

**Methods of determining bromine in sea water and brine.** A. I. KOGAN. *Ukrainskii Khim. Zhur.* 3, Tech. Pt., 131-7(1928).—Various methods for detg.  $\text{Br}^-$  in the presence of large quantities of  $\text{Cl}^-$  were tested. Treadwell's procedure is tedious and probably inaccurate when the  $\text{Br}^-$  content is very low. The methods of Wesselsky and of Berg are more practical, the latter being preferred. Considerable analytical data are given concerning some obtained with these and several other methods. CHAS. BLANC

**Apparatus and method for the rapid determination of "available chlorine" in weak hypochlorite liquor.** J. M. TAYLOR. *Ind. Chemist* 5, 135-6(1929).—If a soln. of hypochlorite is mixed with excess  $\text{H}_2\text{O}_2$ , 1 mol. of  $\text{O}_2$  is evolved for each mol. of  $\text{OCl}^-$  present. An app. is shown and described, which serves to measure the gas pressure produced by this reaction and which is suitable for use in a bleaching plant. A table shows the "available Cl" corresponding to 0-0.75 lbs. pressure per sq. in. W. T. H.

**Method for the estimation of hydrogen in steel.** T. E. ROONEY AND GUY BARR. *J. Iron & Steel Inst.* (advance copy), 8 pp.(May, 1929); *Engineering* 127, 597-8(1929).—The app. described provides for heating the sample in a known vol. of  $\text{N}_2$  and measuring the vol. of  $\text{H}_2$  evolved by means of the Shakespear katharometer. The method is sensitive and permits the detection of 0.5 ml. of  $\text{H}_2$ . Heating for 1 hr. at 800° serves to remove all  $\text{H}_2$  from steel that has been exposed to this gas. W. T. H.

**The manometric determination of small oxygen partial pressures.** OTTO WARBURG AND FRITZ KUBOWITZ. Kaiser-Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 202, 387-9(1928).—An app. with which the  $O_2$  contamination of pure  $N_2$  or  $H_2$  can be detd. has been improved to measure the partial pressure of only a few 0.0001 atm. of  $O_2$ . This consists of a small flask with an extra glass-stoppered side reservoir, and a small chamber in the center of the bottom, giving thus 3 sep. chambers. The reservoir contains 0.2 cc. 0.5  $M$   $FeSO_4$  dissolved in 0.002  $M$   $H_2SO_4$ . The center chamber contains 0.2 cc. 5%  $KOH$  and the main chamber 2 cc. 0.2  $M$   $Fe$ -free  $Na_2P_2O_7$ . The flask is closed by means of a manometer capillary tube through which the analyzed gas is admitted. The manometer is filled with  $H_2O$ . The app. is shaken in the thermostat until the temp. and pressure are equalized. Since acid  $FeSO_4$  does not absorb  $O_2$ , its pressure does not alter during this procedure. Now the reagent from the side reservoir is poured into the main chamber by tilting the app., whereby  $Fe_3P_2O_7$  is produced; this absorbs  $O_2$  very quickly, and a negative pressure results in the system. If this pressure at equil. is designated as  $P_0$  and the total gas pressure (corrected for vapor tension) before the reaction took place is  $P$ , then  $(P_0/P) 100 = \text{Vol. } \% O_2$ . The method was also checked up by means of known amts. of  $O_2$ . By this method  $N_2$  produced by Lindé contained 0.035 vol.  $\% O_2$ ;  $CO$ , 0.15 vol.  $\%$ , while Lindé's argon was  $O_2$  free.

S. MORGULIS

**A new method for the estimation of ozone in air.** M. S. EGOROV. Acad. of Military Med., Leningrad. *Z. Untersuch. Lebensm.* 56, 355-64(1928).—The method recommended is based on the formation of fluorescein from the leuco compd. by the action of  $O_3$ . Dissolve 1 mg. of fluorescein in a few drops of 10%  $NaOH$ , add 10 cc. of satd.  $NaOH$  soln. and shake with  $Zn$  dust until the disappearance of fluorescence indicates complete reduction. Filter and add 1 drop of this soln. to 10 cc. of 0.5%  $NaOH$  contained in a test tube. Draw air through this soln. at a max. rate of 12-15 l. per hr. The vol. of air used is measured when the fluorescence matches that of a standard soln. contg. 1 part of fluorescein in 100,000,000. The fluorescence is stable in alk. soln. and is unaffected by  $H_2O_2$  or oxides of  $N$ ; the method is sensitive, rapid and specific. One part by wt. of fluorescein is produced by 0.96 parts of ozone.

F. P. G.

**Determination of oxygen in steel by the hot extraction method.** GUSTAV THANHEISER AND CHRISTIAN ALEXANDER MÜLLER. *Mitt. Kaiser-Wilhelm-Inst. Eisenforsch. Düsseldorf* 11, 87-94(1929).—The so-called "hot extraction method" consists in heating the material in a vacuum with  $C$  and forming  $CO$  or  $CO_2$ . Until recently a temp. of 1100-1200° was used, but it is now felt that 1400-1600° is necessary in order to insure complete reduction of the oxides. It is now known that  $Fe$  can be heated far above its m. p. by an elec. current of high frequency; this method of heating has been used by Joran and Eckmann for the  $O$  detn. On the basis of the data given in the present paper, however, it is clear that the hot extraction method is still far from perfect. Of the oxides commonly occurring in steel, only  $FeO$  and  $MnO$  are reduced completely, while  $SiO_2$  and  $Al_2O_3$  are only partially reduced at temps. up to 1500°. Difficulties result from the working in a vacuum furnace at such high temps. It is inadvisable to attempt to work with several samples at the same time. W. T. H.

**Rapid method of analysis of bearing alloys.** I. F. ILCHENKO AND K. M. STAKHORSKI. *Ukrainskii Khim. Zhur.* 3, Tech. part, 237-40(1928).—An outline is given of well-known methods for analysis of white metals, such as Babbitt metal, type metal, solder, etc. Low's method of digesting the alloy with concd.  $H_2SO_4$ , filtering off  $PbSO_4$  and titrating with  $KMnO_4$  in  $HCl$  soln. is recommended for the detn. of  $Sb$ .  $Sn$  is detd. iodometrically after reduction with  $Fe$ ,  $Sb$ , or  $Al$  and filtering off the pptd. metals.  $Pb$  is detd. as  $PbSO_4$  and  $Cu$  is detd. colorimetrically as copper-ammonia compd. C. B.

**Rapid method for determination of iron and uranium.** G. SCAGLIARINI AND P. PRATISI. *Ann. chim. applicata* 19, 85-90(1929).—The method depends on the reaction  $2 Fe^{+++} + Cu = 2 Fe^{++} + Cu^{++}$ . Dil. the neutral soln. contg. 0.05-0.3 g. of  $Fe$  as sulfate to 200 cc. in a flask having a stopper provided with a Bunsen valve and with a glass rod to which can be fastened a copper spiral. Then add 20 cc. concd.  $H_2SO_4$ . Heat the soln. to boiling, lower the  $Cu$  into the liquid and boil for 10 mins. Then raise the  $Cu$  spiral, cool, dil. to 500 cc., and titrate with  $KMnO_4$ . In a similar way  $Cu$  has been found to reduce  $U^{VI}$  to  $U^{IV}$ , but 20-45 mins. boiling with  $Cu$  is advisable. When  $U$  and  $F$  are both present, det. both together in one sample; in another, ppt.  $Fe$  as sulfide and det.  $U$  in the filtrate.

A. W. CONTIERI

**Determination of minute quantities of mercury.** RUDOLF THEILENIUS AND ROBERT WINZER. *Z. angew. Chem.* 42, 284-8(1929).—The difficulties which Stock and his co-workers have experienced in detg. traces of  $Hg$  are explained and it is shown how they can be avoided. Instead of dissolving  $Hg$  in  $Cl_2$  aq., it is better to chlorinate with dry

$\text{Cl}_2$  at a higher temp. Precautions are necessary in order to get correct colorimeter readings. Minute directions are given for carrying out the work. W. T. H.

**Determination of minute quantities of mercury.** ALFRED STOCK AND WILHELM ZIMMERMANN. *Z. angew. Chem.* **42**, 429-30 (1929); cf. *C. A.* **22**, 4082.—A reply to he above criticism. W. T. H.

**A new and rapid method for the determination of mercury.** G. SPACU AND G. SUCIU. *Bul. soc. stiinte Cluj* **4**, 403-8 (1929).—If, at the boiling temp., a neutral or a slightly ammoniacal soln. of  $\text{Hg}^{++}$  salt is treated with KI followed by an excess of  $(\text{Cu en}_2)(\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ , the Hg is pptd. completely as  $[\text{Cu en}_2][\text{HgI}_4]$ ; in these formulas "en" signifies ethylenediamine. The ppt. contains 22.49% of Hg. The pptn. is complete in vols. ranging from 80 to 500 cc. even in the presence of considerable  $\text{NH}_4\text{Cl}$  or  $\text{NH}_4\text{NO}_3$ . The reagent can be prepd. by heating a mixt. of 1 mol.  $\text{Cu}(\text{NO}_3)_2$  and 2 mols. ethylenediamine on the water bath until a cryst. crust is obtained. Or, a soln. of  $\text{CuSO}_4$  can be treated with diamine soln. until the characteristic violet color of the complex salt is obtained; an excess of the diamine does no harm. To det. Hg in the presence of Cu, make nearly neutral with  $\text{NH}_4\text{OH}$  and finish the neutralization with ethylenediamine. Heat to boiling, add an excess of KI and an excess of  $(\text{Cu en}_2)\text{SO}_4$ . Dil. with cold water to make the total vol. 25% larger, cool quickly, filter, wash 3-6 times with water contg. the reagents, then 4 times with 2-cc. portions of alc. and finally 3-4 times with ether. W. T. H.

**A new and rapid method for the gravimetric determination of cadmium.** G. SPACU AND G. SUCIU. *Bul. soc. stiinte Cluj* **4**, 409-12 (1929); cf. *C. A.* **22**, 1927.—With Cd a ppt. contg. 13.99% of Cd can be obtained by the action of KI and  $[\text{Cu en}_2](\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ . To 100-300 cc. of neutral soln. contg. Cd, add an excess of KI and heat to the b. p. Then add a hot, concd. soln. of  $[\text{Cu en}_2](\text{NO}_3)_2$ . Cool completely, filter and wash first with a soln. contg. 1% of KI and 0.3% of  $[\text{Cu en}_2](\text{NO}_3)_2 \cdot 2\text{H}_2\text{O}$ , then with 4-6 2-cc. portions of alc. and finally 3-4 times with ether. W. T. H.

**Electroanalyses with mercury cathodes.** WILHELM MOLDENHAUER, K. F. A. EWALD AND O. ROTH. *Tech. Hochschule Darmstadt. Z. angew. Chem.* **42**, 331-4 (1929).—After describing the theory and technic of electrolytic work with a Hg cathode in the spoon-shaped electrode devised by M., the following new procedures are described.

**Detn. of Pb from  $\text{HNO}_3$  solns.**—To 50 cc. of soln. contg. about 0.1 g. of Pb, add 2 cc. of concd.  $\text{HNO}_3$  and 0.5 cc. of a concd. soln. of  $\text{NH}_2\text{NH}_2$  in concd.  $\text{HNO}_3$ . Electrolyze with a current of 1 amp. for 1 hr. while rotating the anode. When the electrolysis is finished, stop the stirring and drop the Pt-foil anode into the Hg of the cathode so that the current will not be broken on removing the electrodes from the beaker. When this is accomplished, wash with water, disconnect the current, remove as much of the water as possible and dry for 1.5 hrs. in a vacuum over concd.  $\text{H}_2\text{SO}_4$ .

**Detn. of Ag from ammoniacal soln.**—To 50 cc. of soln. contg. about 0.1 g. of Ag as nitrate, add 10 cc. of concd.  $\text{NH}_4\text{OH}$  and 6 g. of  $\text{NH}_4\text{NO}_3$ . Electrolyze with a current of 0.5 amp. at the start (3.5-4 v.). If the soln. contains any chloride, use fresh Hg for each analysis.

**Detn. of Ni from ammoniacal soln.**—To a  $\text{NiSO}_4$  soln. add 5 g. of  $\text{NH}_4\text{NO}_3$  and an excess of concd.  $\text{NH}_4\text{OH}$ . Electrolyze with a current of 0.5-0.75 amp. (about 5 v.) and add more  $\text{NH}_4\text{OH}$  from time to time.

**Detn. of Zn from ammoniacal soln.**—Add  $\text{NH}_4\text{NO}_3$  and  $\text{NH}_4\text{OH}$  as with Ni. Use a current of 0.4-0.8 amp.

**Detn. of Ag from KCN soln.**—To the  $\text{AgNO}_3$  soln. add KCN until the  $\text{AgCN}$  ppt. dissolves and use about 1 g. of KCN in excess. To avoid formation of  $(\text{CN})_2$  at the anode, add some KOH soln. Electrolyze with a current of 0.3-0.4 amp. at 3 v.

**Sepn. of Ag and Cu.**—To deposit Cu from dil.  $\text{HNO}_3$  soln. keep the e. m. f. at 1.2 v. To prevent anodic deposition of oxide, add a little dil. hydrazine sulfate soln. or some alc.; 0.16 g. of Ag will deposit in 1.75 hr. To deposit Cu use another cathode and increase the current to about 1 amp.

**Sepn. of Ag and Pb.**—To 50 cc. of nitrate soln. contg. about 0.1 g. of each metal, add 3 cc. of concd.  $\text{HNO}_3$ , 1 g. of tartaric acid and 2 cc. of 96% alc. Regulate the current as for the sepn. of Ag and Cu but add additional hydrazine in the Pb detn.

**Sepn. of Ag and Zn.**—Add 3 cc. of concd.  $\text{HNO}_3$  to the neutral soln. of the nitrates and 1 cc. of 96% alc. Keep the potential at 1.2 v. for the deposition of Ag and use 1.5 amp. for the Zn.

**Sepn. of Cu and Ni.**—Use a soln. contg. free  $\text{H}_2\text{SO}_4$ , keep the potential at 2.1 v. for the deposition of Cu and use a current of 1.5 amp. to deposit Ni.

**Sepn. of Zn from Pb or Ag from Zn and Pb.**—As electrolyte use a soln. contg. up to 0.1 g. of each metal in the form of nitrates. Add 10 cc. of 2 N  $\text{H}_2\text{SO}_4$  to ppt. the Pb as  $\text{PbSO}_4$  and deposit the Zn at 50° in a stirred electrolyte, using a current of 2 amp. at 5-6 v. When Ag is present, add a little tartaric acid and alc. to the  $\text{HNO}_3$  soln. and deposit the Ag as described for the Ag-Pb sepn. Then add  $\text{H}_2\text{SO}_4$  and ppt. the Zn as just described. After the Zn detn. siphon off the liquid above the  $\text{PbSO}_4$  ppt. as completely as possible,

and dissolve the ppt. in concd. ammoniacal tartrate soln. Add 3 g. of  $\text{NH}_4\text{NO}_3$  and electrolyze with a current of 0.8 amp. at 3.5–4.5 v. From time to time break the circuit to allow  $\text{PbO}_2$  to dissolve from the anode.

W. T. H.

**Method for the quantitative separation of nickel and calcium.** GEORG W. KÜHL. *Chem.-Ztg.* 53, 279(1929).—When only Ni and Ca are present, make the soln. ammoniacal and ppt. the Ca first as oxalate; in the filtrate det. Ni by the diacetyl dioxime method.

W. T. H.

**Determination and separation of rare metals from other metals.** XV. Quantitative analysis of gallium. 2. LUDWIG MOSER AND ALFRED BRUKL. *Monatsh.* 51, 325–33 (1929); cf. *C. A.* 23, 2387.—Considerable difficulty was encountered in finding a good method for sepg. Ga from certain trivalent and quadrivalent cations. The best reagent for this purpose appears to be cupferron. *Sepn. of Ga from Al.*—To the neutral soln. contg. 0.01–0.3 g. of Ga, add  $\text{H}_2\text{SO}_4$  to make the soln. 2 N and bring the vol. to 200–300 cc. At room temp. add a 6% soln. of cupferron, using 6 times as much as there is Ga present. Filter off the white, flocculent ppt. through a paper filter in a Pt cone and finally apply gentle suction. The first filtrate usually comes through turbid. Add 1–2 cc. more of reagent and filter through the same filter. If the filtrate remains clear for 2 hrs. the complete pptn. of Ga is assured. Wash with small portions of 2 N  $\text{H}_2\text{SO}_4$  and drain each time by gentle suction. When free from chloride, ignite and weigh as  $\text{Ga}_2\text{O}_3$ . Evap. the filtrate to fumes and ppt. the Al as  $\text{Al}(\text{OH})_3$  by dilg. and adding  $\text{NH}_4\text{OH}$ , or, if the quantity of Al is small, ppt. by adding tannin to the  $\text{AcOH}$  soln. If more than 2 g. of Al is present, some Al will be pptd. with the Ga; otherwise a single pptn. is adequate for the sepn. *Sepn. of Ga from Cr.*—Proceed in precisely the same manner. *Sepn. of Ga from In.*—The procedure is the same except that special care must be taken in washing the Ga ppt. It is best to have a little cupferron in the acid wash water. If the In predominates, a double pptn. is necessary. If In is present in the ignited  $\text{Ga}_2\text{O}_3$ , it will show a yellow tint. *Sepn. of Ga from U.*—The same method works here also, provided the U is all present in the sexivalent condition. The absence of reducing agents is necessary since  $\text{U}^{\text{IV}}$  forms a ppt. with cupferron. *Sepn. of Ga from Ce.*—The same method applies. *Sepn. of Ga from Fe.*—Two methods have been found to give results. The first depends upon the pptn. of the Ga by  $\text{Na}_2\text{S}_2\text{O}_3$ , as in the well-known method for sepg. Fe from Al, and the second depends upon the pptn. of Fe as  $\text{FeS}$  in an ammoniacal soln. contg. tartaric or sulfosalicylic acid. If the Fe predominates and little Ga is present, nearly neutralize the soln. with  $\text{Na}_2\text{CO}_3$  and add  $\text{Na}_2\text{S}_2\text{O}_3$  until the violet color of the  $\text{Fe}^{\text{III}}$  complex disappears, showing that complete reduction has been accomplished. Boil for 15 mins. and then, at 5-min intervals, add 10-cc. portions of aniline. Filter while hot and wash till all Na salt is removed. Fuse the ignited  $\text{Ge}_2\text{O}_3$  ppt. with  $\text{K}_2\text{S}_2\text{O}_7$  and repeat the sepn. as given for one of the 2 following cases. (a) If not more than 0.3 g. of oxides are present, treat the soln. with 10% sulfosalicylic acid and then with ammonia until a red color is obtained. Introduce  $\text{H}_2\text{S}$  into the clear, boiling soln. Filter off the  $\text{FeS}$  and wash the ppt. with water contg.  $(\text{NH}_4)_2\text{S}$  and  $(\text{NH}_4)_2\text{SO}_4$ . Make the filtrate acid with  $\text{AcOH}$ , boil off  $\text{H}_2\text{S}$  and ppt. the Ga by  $\text{NH}_4\text{OAc}$  and tannin. (b) If, finally, much Ga and little Fe are present, pour the nearly neutral soln. into an excess of hot, dil.  $\text{NH}_4\text{OH}$  to ppt.  $\text{Fe}(\text{OH})_3$ . Since the ppt. always adsorbs some Ga, dissolve in  $\text{HCl}$  and continue as in (a). In the combined filtrates det. the Ga by pptn. with tannin in dil.  $\text{AcOH}$  soln.

W. T. H.

**Rapid determination of tin in tin plate and tin plate waste.** JACOB HÄGE. *Chem.-Ztg.* 53, 287(1929).—Wind 10 g. of material into a spiral, fasten it to a Pt wire and suspend the metal over hot, 6 N  $\text{HCl}$  until the appearance of the plate indicates that all of the Sn has been removed. Reduce the resulting soln. with Al or Zn using a Bunsen valve or a Gockel valve contg.  $\text{NaHCO}_3$  soln. Dissolve the metal in  $\text{HCl}$  and titrate with  $\text{I}_2$  soln.

W. T. H.

**Detection of small quantities of vanadium.** ANTON FÖLSNER. *Chem.-Ztg.* 53, 259(1929).— $\text{Pb}(\text{OAc})_2$  will give a turbidity in solns. which have given a negative test for V with  $\text{H}_2\text{O}_2$ .

W. T. H.

**Determination of zinc in pyrites.** LORENZ L. HAGEN. *Tids. Kemi Bergvesen* 8, 34–5(1928).—Heat 3 g. of pyrite with 25 cc. of concd.  $\text{HCl}$  in a 500-cc. beaker. Add 5–10 cc. of concd.  $\text{HNO}_3$  and boil some more. Add a little  $\text{Br}_2$ , evap. nearly to dryness, and add 10 cc. of concd.  $\text{NH}_4\text{OH}$ . Stir the residue with a glass rod with rubber, add 25 g.  $\text{NH}_4\text{Cl}$  and 20 cc. of concd.  $\text{NH}_4\text{OH}$  and stir again. Transfer to a 300 cc.-measuring flask, filter and take 100 cc. for the detn. of Zn. Add  $\text{Na}_2\text{S}_2\text{O}_4$  to ppt. Cu. Filter and titrate with  $\text{K}_4\text{Fe}(\text{CN})_6$ .

A. DROGSETH

**Zirconium.** IV. Precipitation of zirconium by phosphates. RUFUS D. REED

AND JAMES R. WITHEROW. Ohio State Univ. *J. Am. Chem. Soc.* **51**, 1311-5(1929); cf. *C. A.* **23**, 2390.—Zr(SO<sub>4</sub>)<sub>2</sub> can be used as a precipitant of K but since this reagent also reacts with Na<sub>2</sub>Co(NO<sub>2</sub>)<sub>6</sub>, it is necessary to remove Zr before the soln. can be treated with Na<sub>2</sub>Co(NO<sub>2</sub>)<sub>6</sub>, to see if the pptn. of K has been complete. A 5-fold excess of (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> or NaNH<sub>2</sub>HPO<sub>4</sub> in the presence of 0.344-0.688 N H<sub>2</sub>SO<sub>4</sub>, 0.269 N HNO<sub>3</sub>, or 0.204 N HCl will serve to remove Zr completely, but Na<sub>2</sub>HPO<sub>4</sub> is less efficient. In the absence of acid, the pptn. of Zr as phosphate is incomplete. W. T. HALL

Determination of cyanides and oxycyanides of mercury by the mercurimetric method. AL. IONESCO-MATIU AND MLE. A. CARALE. Pharm. Lab. Univ. Jassy. *J. pharm. chim.* **8**, 258-63; *Bul. soc. chim. România* **10**, 127-30(1928); cf. *C. A.* **21**, 2445, 3575.—Gently heat Hg(CN)<sub>2</sub> (A) or Hg(CN)<sub>2</sub>·HgO (B) (about 0.05 g.) with 20 cc. concd. H<sub>2</sub>SO<sub>4</sub> for 10-20 mins.; cool, pour into 120 cc. H<sub>2</sub>O, add KMnO<sub>4</sub> soln. till a pink color is obtained and 15 drops of 10% Na(NO)Fe(CN)<sub>6</sub>. Titrate the turbid liquid with 0.1 N NaCl until it clears. One cc. NaCl = 0.01275 g. A or 0.01187 g. B.

S. WALDBOTT

Notes on molybdates, nitrophosphomolybdates, tungstates and phosphotungstates. TEOFILO GASPARY ARNAL. *Ann. chim. anal. chim. appl.* **11**, 97-103(1929).—The reactions of the following reagents with numerous ions were studied: (A) Na molybdate in 5% aq. soln., (B) NH<sub>4</sub> molybdate in satd. aq. soln., (C) Na nitrophosphomolybdate (Na<sub>2</sub>HPO<sub>4</sub>, Na molybdate and HNO<sub>3</sub>), (D) Na tungstate in 5% soln., (E) Na phosphotungstate in 5% soln. The following results were obtained. *With (A)* no effects were obtained with Li, Na, NH<sub>4</sub>, K, Rb, Cs, Be, Mg, Zn, Hg<sup>++</sup>, Mn, Ni and Co. Cu gives a greenish blue ppt., sol. in NH<sub>4</sub>OH and in HNO<sub>3</sub>; Ag, an abundant white ppt.; Ca, a ppt. that forms slowly but more quickly when alc. is added (the ppt. is sol. in HNO<sub>3</sub>); Sr and Ba give similar ppts. with diminishing soly. in the order named; Al gives a white ppt. forming slowly, sol. in HNO<sub>3</sub> and converted to hydroxide by NH<sub>4</sub>OH; Pb, abundant ppt., sol. in HNO<sub>3</sub>; Th is like Al except that the ppt. forms more readily, Bi is like Th; UO<sub>2</sub> gives a light yellow ppt., sol. in HNO<sub>3</sub> and darkened by adding NH<sub>4</sub>OH; Fe, a ppt., which is dissolved by excess FeCl<sub>3</sub>. *With (B)* no ppt. is obtained with Li, Na, Cu, Ag, Be, Mg, Ca, Zn, Cd, Ba, Hg<sup>++</sup>, Al, UO<sub>2</sub>, Mn, Ni and Co. NH<sub>4</sub> gives nothing in the cold; on heating it gives a yellow ppt. insol. in HNO<sub>3</sub> but dissolved by NH<sub>4</sub>OH; K, Rb and Cs give the same effect as with NH<sub>4</sub> but the soly. of the ppts decreases in the order named; Hg gives an abundant ppt. in the cold, which dissolves on heating but reappears on cooling; Tl and Pb give white ppts. sol. in an excess of the reagent (on heating the ppt. is obtained again and is yellower in color); Th gives a ppt. sol. in excess reagent; on standing a gelatinous mass seps. out, which is transparent at first but eventually becomes opaque; Bi is like Pb; FeCl<sub>3</sub> gives a beautiful blue color. Alk. molybdates, in the presence of FeCl<sub>3</sub>, give analogous ppts., sol. in an excess of FeCl<sub>3</sub>. If, to this soln. a little phosphate is added, a blue coloration is obtained, which is characteristic. *With (C)* no effects are obtained with Li, Na, NH<sub>4</sub>, K, Rb, Cs and Mg ions. Cu gives a light blue ppt. sol. in NH<sub>4</sub>OH; Ag, a yellow ppt. sol. in NH<sub>4</sub>OH; Be, a very abundant ppt. sol. in an excess of Be(NO<sub>3</sub>)<sub>2</sub>, but insol. in NH<sub>4</sub>OH; Ca, slow pptn.; with Sr and Ba the reaction is even slower (the ppts. are insol. in NH<sub>4</sub>OH); Zn and Cd give ppts. of which the Zn salt is more insol. in water but dissolves in NH<sub>4</sub>OH, whereas the Cd salt does not. Hg<sup>+</sup> gives a brown ppt.; Hg<sup>++</sup>, a yellow ppt.; Al, a dense ppt. sol. in NH<sub>4</sub>OH; Tl is like Al; Pb gives a white ppt. insol. in NH<sub>4</sub>OH; Th, a ppt., which changes to Th(OH)<sub>4</sub> with NH<sub>4</sub>OH; Bi, a ppt., which changes color with NH<sub>4</sub>OH; UO<sub>2</sub>, a yellow ppt.; on adding NH<sub>4</sub>OH the color is more pronounced; Mn gives a pink ppt. dissolved by NH<sub>4</sub>OH and then a brown ppt. appears, which contains Mn; Fe, a pale yellow ppt. converted to Fe(OH)<sub>3</sub> by NH<sub>4</sub>OH; Ni, a bluish green ppt., sol. in NH<sub>4</sub>OH; Co, a bluish pink ppt. also sol. in NH<sub>4</sub>OH. *With (D)* no reactions are obtained with Li, Na, Cu, Hg, Be, Zn, Sr, Cd, Ba, Hg, Al, Mn, Fe (except a coloration), Ni and Co, but ppts. are obtained as follows: NH<sub>4</sub> gives a white ppt. sol. in NH<sub>4</sub>OH and insol. in HNO<sub>3</sub>; K, a white ppt. insol. in HNO<sub>3</sub> and sol. in NH<sub>4</sub>OH; Rb and Cs give the same; Tl gives a ppt. insol. in HNO<sub>3</sub> but not very insol. in water; Pb, a ppt. sol. in HNO<sub>3</sub> and insol. in NH<sub>4</sub>OH; Hg<sup>++</sup> is the same except the ppt. darkens with NH<sub>4</sub>OH; Bi gives a ppt. sol. in HNO<sub>3</sub> and altered by NH<sub>4</sub>OH; UO<sub>2</sub>, a ppt., which is formed slowly and which is sol. in HNO<sub>3</sub> and insol. in NH<sub>4</sub>OH. The effect of alc. upon all of these reactions is discussed and some 19 possible applications to analytical chemistry are outlined.

W. T. HALL

Determination and separation of nitrous acid by the esterification method. WALDEMAR M. FISCHER AND ARVID SCHMIDT. Univ. Riga. *Z. anorg. allgem. Chem.* **179**, 332-8(1929).—If a soln. of alkali nitrite is treated with alc. at *pH* = 0.2-4, the esterification of the HNO<sub>2</sub> takes place so rapidly that the presence of substances such as NH<sub>4</sub>

salt, nitrate, chlorate, iodate, perchlorate, chromate, ferricyanide, formate or oxalate does not interfere seriously. If a ferrous salt is present, it reacts with  $\text{HNO}_3$  to form a characteristic brown coloration, but if an excess of  $0.1\text{ }N\text{ K}_2\text{Cr}_2\text{O}_7$  is added, it is oxidized and  $\text{HNO}_3$  is formed again. The app. recommended consists of a 150-cc. dropping funnel to serve as reaction vessel. It has a cylindrical shape and is closed at the top with a 3-holed rubber stopper carrying a small dropping funnel, whose stem reaches nearly to the bottom of the larger funnel and is bent upwards at the bottom, a tube for introducing  $\text{CO}_2$ , which ends at the very bottom of the larger funnel, and a small deplegator tube filled with glass beads. The last-mentioned tube is connected with a specially constructed 10-bubble tube that is provided with a glass stopcock at the bottom for emptying the tube and at the top has a side arm connected to a filter bottle contg. KI soln. and is closed by a stopper with another dropping funnel. To carry out the analysis the aq. soln. of the nitrite and 5–10 cc. of MeOH are placed in the reaction vessel and the 10-bubble Meyer tube is filled with 20% KI soln. Air is expelled by a rapid stream of  $\text{CO}_2$ . Then through the funnel attached to the bubble tube, 10 cc. of  $5\text{ }N\text{ HCl}$  is added to the KI soln. and through the other funnel 5 cc. of  $5\text{ }N\text{ HCl}$  or AcOH is added to the nitrite soln. Gas is led through the app. at the rate of 3–4 bubbles per min. and after 45 mins. the KI soln. is withdrawn and the liberated  $\text{I}_2$  titrated with thiosulfate soln. The method was tested with 10-cc. portions of  $0.1\text{ }N\text{ NaNO}_2$  soln. and good results were obtained except in the presence of  $\text{NH}_2\text{OH}$ ,  $\text{NH}_4\text{NH}_2$ , aniline salts, bromates, sulfites, ferrocyanides and permanganates, all of which react with  $\text{HNO}_3$  so rapidly that the esterification is incomplete.

W. T. HALL

Colorimetric method for the determination of phosphoric acid. II. C. BORDEIANU, *Ann. sci. univ. Jassy* 15, 372–9(1929); cf. C. A. 22, 1297.—The method previously described for the analysis of fertilizers and such products has been applied to the detn. of  $\text{H}_2\text{PO}_4$  in urine, in glycerophosphates and in glucose sirup.

W. T. H.

Colorimetric determination of phosphoric acid by Denigès' method. S. N. ROZANOV, *Trans. Sci. Inst. Fertilizers* (Moscow) 1928, No. 55, 139–58.—Rozanov analyzed 40 samples of rock phosphate for P by the Denigès' method investigating: (1) the influence of the quantity of aqua-regia used in decomp. the rock phosphate on the accuracy of the method; (2) the limits of the  $\text{P}_2\text{O}_5$  concn. which would give reliable results with the Denigès' method; (3) the reliability of the method as compared with the method of double pptn. It was found that the quantity of aqua-regia used in analyses of this type has no influence on the colorimetric detn.; 0.5 to 0.3 mg. of  $\text{P}_2\text{O}_5$  per l. are the optimal limits for this method. The max. deviation when compared with the double pptn. was 1%.

J. S. JOFFE

Analysis of sodium sulfide. JOHANNES PAESSLER, *Ledertech. Rundschau* 21, 61–2 (1929).—Dissolve 10 g. of  $\text{Na}_2\text{S}$  in 1 l. of  $\text{H}_2\text{O}$ , taking care to avoid loss; filter to remove FeS. Pipet 25 cc. of the filtrate into a slight excess of  $0.1\text{ }N\text{ I}$  soln. and titrate with  $0.1\text{ }N\text{ Na}_2\text{S}_2\text{O}_3$  soln.; this determines both  $\text{S}^{--}$  and  $\text{S}_2\text{O}_3^{--}$ . Det.  $\text{S}_2\text{O}_3^{--}$  by adding to the  $\text{Na}_2\text{S}$  soln. an equal vol. of  $\text{ZnSO}_4$  soln., (50 g. of crystals per l.), then filter and titrate with I soln.

I. D. CLARKE

Note on the determination of sulfate in fluorides, especially the cryolites. H. GINSBERG AND G. HOLDER, *Z. angew. Chem.* 42, 314–7(1929).—Extn. of the sulfate by boiling with  $\text{Na}_2\text{CO}_3$  soln. is uncertain because of the difficulty in removing  $\text{Al}(\text{OH})_3$  completely in the presence of  $\text{F}^-$ . Ehrenfeld's method of pptg.  $\text{BaSO}_4$  and  $\text{BaF}_2$  and treating with  $\text{CaCr}_2\text{O}_7$  soln. to dissolve out the F is capable of giving good results, but the work is tedious. The benzidine sulfate method of Raschig is not much better. Ehrenfeld's method of reducing the sulfate to sulfide by means of Zn dust is rapid and gives fairly good results. It is recommended, in this case, to treat 1 g. of fluoride with 10 g. of Zn dust in a glazed porcelain crucible heating 0.5 hr. in a stream of  $\text{H}_2$ . Cool in the  $\text{H}_2$ , transfer to a Corleis flask, add a little  $\text{Al}(\text{OH})_3$  and some colloidal  $\text{SiO}_2$ , treat with  $6\text{ }N\text{ HCl}$  and absorb the  $\text{H}_2\text{S}$  in  $\text{Cd}(\text{OAc})_2$  soln., as in steel analysis. As standard method, however, the following procedure is recommended, which provides for the preliminary removal of all  $\text{F}^-$  by evapg. several times with  $\text{HCl}$  in the presence of pulverulent  $\text{SiO}_2$ . Mix 2 g. of cryolite with 12 g. of soda and fuse at  $1000^\circ$  for 30 mins. in a Pt crucible. Extract the melt with water and filter. Make the filtrate acid with  $\text{HCl}$  and boil off  $\text{CO}_2$ . Add  $\text{NH}_4\text{OH}$  to ppt.  $\text{Al}(\text{OH})_3$ , filter cold, redissolve in  $\text{HCl}$  and repeat the pptn. working in the cold. To the combined filtrates in a porcelain dish, add about 1 g. of  $\text{SiO}_2$  powder and evap. 5 times with 50-cc. portions of concd.  $\text{HCl}$ . Finally treat with  $\text{NH}_4\text{OH}$  to ppt.  $\text{Al}(\text{OH})_3$  that was held in soln. as  $\text{AlF}_3$ ; then ppt.  $\text{BaSO}_4$  in the usual manner. This method is too tedious for every day work.

W. T. H.

Test for tungstates and for molybdates. MME. MARIANNE PAPAFIL AND R.

CHERNATSCO. *Ann. sci. univ. Jassy* 15, 384-6(1929).—Neutral solns. of tungstates and molybdates give ppts. with a soln. of tetramethyldiaminodiphenylmethane (D) in very dil. AcOH. As reagent, prepare a soln. of 1.5 g. of (D) in 300 cc. of water contg. 10 cc. of AcOH; filter and add dil.  $\text{NH}_4\text{OH}$  dropwise until a faint opalescence is produced. Filter again. A blue ppt. is obtained when 2 cc. of  $\text{NH}_4$  molybdate soln. (0.06 g. per l.) is treated with 2-4 cc. of the reagent. An opalescence is obtained with the same vol. of Na tungstate soln. (0.25 g. per l.). The reagent also gives a green ppt. with a sol. vanadate. W. T. H.

Detection of bromide and iodide ions. ERNST MURMANN. *Oesterr. Chem.-Ztg.* 32, 36-7(1929).—The detection of Br by the formation of eosin is very sensitive, but when  $\text{HNO}_2$  or  $\text{HNO}_3$  is present, the test is likely to fail. This difficulty can be overcome by reducing with Zn. It is convenient to use a Drechsel wash bottle through which a stream of air is passing. When 0.1 mg. of KBr is present in 100 cc. of soln. and the gases from the bottle are led through a restricted tube contg. cotton that has been dyed yellow with fluorescein, the red color appears within 10 mins. It is possible to det. I similarly by using cotton that has been moistened with 0.5% KI soln. in 50% glycerol and dried. Make the soln. of iodide distinctly acid with  $\text{H}_2\text{SO}_4$ , add 0.1 g. of  $(\text{NH}_4)_2\text{S}_2\text{O}_8$  and pass air through the flask. The presence of 0.1 mg. of KI in 100 cc. of soln. gives a blue test. If not less than 1 mg. of KI is present, it is possible to test for both Br and I in one expt. In this case use  $\text{KMnO}_4$  to liberate the halogen and lead the gas first to the fluorescein and then to the KI-starch. Data are given to show that the method compares favorably with that of Fellenberg and is of about the same sensitivity. W. T. H.

An improved chloride method for organic material and foods. MAX BIRNER. *Z. ges. expul. Med.* 61, 700-6(1928).—Heat 2-5 g. of the sample in a Ni crucible on the water bath with an excess of NaOH until the sample is broken down to the consistency of an even pulp. Add a little  $\text{KNO}_3$  and heat the crucible to  $120^\circ$  with a final heating of not over  $450^\circ$ . If the mass does not foam on the addition of a small amount of  $\text{KNO}_3$ , the oxidation of organic matter is completed. On cooling the mass should be white. Dissolve it in hot water, filter, make strongly acid with  $\text{HNO}_3$  and add an excess of standard  $\text{AgNO}_3$  soln. To destroy traces of nitrite, boil for at least 15 mins., cool and add, dropwise,  $\text{KMnO}_4$  until there is a persistent color. Decolorize with a few drops of  $\text{Fe}^{+1}$  sulfate soln. Titrate with  $\text{HgNO}_3$  by the Volhard method. F. L. D.

Determination of alcohol in the presence of acetaldehyde. YOSHINORI TOMODA. Tokyo Imp. Univ. *J. Soc. Chem. Ind.* 48, 77-9T(1929).—The detn. of EtOH by the aeration and oxidation method of Dox and Lamb (*C. A.* 11, 242) is not satisfactory in the presence of AcH. T. has studied the behavior of an aq. soln. of AcH-bisulfite upon distn. and aeration. AcH is not volatilized with EtOH in the presence of  $\text{NaHSO}_3$  during aeration if the reaction of the mixt. is acid. On this basis, the following method is recommended. To 5 cc. of EtOH soln. contg. AcH add 4.5 g. of  $\text{NaHSO}_3$ ; after standing 15 mins., aerate the mixt. at the rate of 15 l. per hr. Absorb the vapor in 15 cc. of concd.  $\text{H}_2\text{SO}_4$ . After about 6 hrs. mix the  $\text{H}_2\text{SO}_4$  with 15 g. of  $\text{K}_2\text{Cr}_2\text{O}_7$  in 50 cc. of  $\text{H}_2\text{O}$  in a distg. flask; wash out the absorption tubes with 50 cc. of  $\text{H}_2\text{O}$  and distil off AcOH by heating with steam for 15 mins. Titrate with 0.1 N  $\text{Ba}(\text{OH})_2$  (1 cc. = 0.0046 g. EtOH). The method, which was found accurate to 3%, was not affected by  $\text{HCO}_2\text{H}$ , AcOH, glycerol, sucrose, or AcH. A. S. CARTER.

Dimethylhydroresorcinol as a reagent for aldehydes. L. ROSENTHALER. *Z. angew. Chem.* 42, 317-8(1929).—Replying to a criticism of Vorlander (*C. A.* 23, 1894), R. points out that V., rather than Erdmann, is actually credited with the discovery of this test in R's textbook. W. T. H.

Analysis of dilute solutions of methanol. S. S. KISTLER. College of the Pacific. *Science* 69, 457-8(1929).—Distil the soln. contg. the alc. until it is known that no other oxidizable material is present. All of the MeOH should be in the first half of the distillate. To an aliquot part of the distillate add an excess of standard  $\text{Na}_2\text{Cr}_2\text{O}_7$  and make 12 N with  $\text{H}_2\text{SO}_4$ . Heat on the water bath for 10 mins. Titrate the excess dichromate with  $\text{FeSO}_4$ , detg. the end point electrometrically. W. T. H.

Studies of anthracene. I. The analysis. H. A. J. PIETERS AND TH. H. KOENEN. *Chem. Weekblad* 26, 222-4(1929).—The crude product is extd. with 4 N  $\text{H}_2\text{SO}_4$  to remove the bases. The phenanthrene is then extd. with toluene,  $\text{CS}_2$ , or solvent naphtha. Since anthracene itself is also somewhat sol., the accuracy of the sepn. will be smaller with preps. poor in anthracene. The remaining mixt. of anthracene and carbazole is analyzed for the latter by a  $\text{N}_2$  detn. and for the former by one of the classical methods. G. CALINGAERT.

A simple method for the estimation of antimony in organic antimony compounds.

**SUDHAMOY GHOSH.** Calcutta School of Trop. Med. and Hyg. *Indian J. Med. Research* 16, 457-60(1928).—To 0.05-0.07 g. substance add 2 g.  $K_2SO_4$  crystals and 3 cc. pure, As-free  $H_2SO_4$ . Treat the mixt. gently and with occasional shaking in the beginning, until colorless; dilute with 25 cc.  $H_2O$ , and heat for 3 to 5 mins. to remove any  $SO_2$ , adding a little freshly ignited pumice to prevent bumping. While this is still warm, add 3 to 4 cc. concd.  $HCl$ , cool the whole quickly to room temp. and make up to 100 cc. Make 25 cc. just alk. with 40%  $NaOH$  and then just acid with tartaric acid (1%). Add 10 cc. of 4%  $NaHCO_3$  and 25 to 30 drops of 1% starch soln. Titrate the whole against 0.01  $N$   $I$  soln.

FRANCES KRASNOW \*

**Determination of benzene and toluene in gases.** FERDINAND SCHULZ. *Collection Czechoslov. Chem. Comm.* 1, 228-33(1929).—Gustavson in 1883 devised a simple test for the detection of aromatic hydrocarbons in gasoline by bromination in the presence of anhydrous  $AlCl_3$ . If the resulting hexabromobenzene and the pentabromotoluene are weighed, good results are obtained. By washing the bromination products with  $MeOH$ , the aromatic hydrocarbons can be sepd. from ethylene and from the hydrocarbons of gasoline. In this way it is possible to det. even small quantities of aromatic hydrocarbons in a small sample of gas.

W. T. H.

**Micropotentiometric determination of reducing carbohydrates.** JOSEPH B. NIEDERL AND RALPH H. MÜLLER. N. Y. Univ. *J. Am. Chem. Soc.* 51, 1356-9(1929).—By using 2 vessels filled with Fehling's soln. of the same original concn., connected by an agar- $KCl$  bridge and with electrodes in circuit with a potentiometer, on heating one of the vessels and adding sugar soln. from a microburet, a concn. cell is produced and the progress of the reaction can be followed. The end point is very marked. The more important carbohydrates were studied by this method and their reduction values detd. In this way 3 mg. of sugar can be detd. with an accuracy of about 1%; by carrying out the work with a microbalance and microburet, good results can be obtained with as little as 0.05 mg. of reducing sugar.

W. T. HALL

**Volumetric determination of vanadium by means of potassium iodate.** ERNEST H. SWIFT AND RAYMOND W. HOEPPEL. Calif. Inst. Tech. *J. Am. Chem. Soc.* 51, 1366-71(1929).—The method depends upon the reduction of  $V$  from a valence of 5 to 4 by means of a measured vol. of  $KI$  soln., in a small vol. of soln., which is 6-8  $N$  in  $HCl$  and out of contact with air. Then by keeping the soln. at least 6  $N$  in  $HCl$ , the liberated  $I_2$  and the excess iodide can be titrated with  $KIO_3$  soln. Since  $2I_2$  or  $2HI$  each react with 1 mol. of  $KIO_3$  to form  $ICl$ , it is easy to tell how much of the  $KI$  was oxidized by the vanadate.

W. T. HALL

**Determination of reducing sugars by the ferricyanide method.** AL. IONESCU-MATHIU. *Ann. sci. univ. Jassy* 15, 363-71(1929).—If a hot, alk. soln. of  $K_3Fe(CN)_6$  contg. picric acid as indicator, is treated with a reducing sugar, the ferricyanide is reduced to ferrocyanide; when the ferricyanide has all been reduced, the yellow color changes to red in consequence of the reduction of the picric acid by the excess sugar. For such a titration a 0.5% soln. of glucose, a 1% soln. of picric acid and a soln. contg. 46 g.  $K_3Fe(CN)_6$  and 46 g.  $KOH$  per l. are suitable. With smaller quantities of reducing sugar, it is better to add some ferricyanide to the sugar soln. and to det. the quantity reduced by titration of the resulting ferrocyanide with  $KMnO_4$  in the presence of acid. Five mols. of ferricyanide oxidize 1 mol. of glucose. The application of these tests to biol. fluids such as blood, urine, etc., as well as to glucose, maltose and lactose solns. is described at some length.

W. T. H.

**Volumetric method for the analysis of urotropine.** C. V. BORDEIANU. *Ann. sci. univ. Jassy* 15, 380-3(1929).—In 1926, Mrs. Kollo and B. Angelesco published a method for the analysis of urotropine, which can be completed in 35 mins. and which is based upon the formation of a salt of urotropine with picric acid. The excess of picric acid is detd. by titration with  $NaOH$ . A study of this method shows that it is altogether unreliable.

**Detection of mercury vapor.** BIRGER W. NORDLANDER. U. S. 1,711,742, May 7. A flexible strip of material such as paper having a film of a compd. of Se and S is used for detection of Hg vapor, *e. g.*, in air or flue gas. An app. is described.

**Determining the gas content of solids.** W. HESSENBRUCH (to C. Lorenz A.-G.). Brit. 299,303, Oct. 22, 1927. A sample under test is heated *in vacuo* in a furnace, which is evacuated before the introduction of the sample; the sample is introduced in such a manner as to avoid breaking the vacuum. An app. is described in which a lock chamber is used in connection with a quartz-tube furnace heated by a high-frequency coil and contg. a graphite crucible within a magnesia crucible. Various structural features are described.

## 8—MINERALOGICAL AND GEOLOGICAL CHEMISTRY

EDGAR T. WHERRY AND J. F. SCHAIERER

**The Tasmanian tectite—Darwin glass.** T. W. E. DAVID, H. S. SUMMERS AND G. A. AMPT. *Proc. Roy. Soc. Victoria* 39, 167–90(1927); *Mineralog. Abstracts* 3, 538. Darwin glass from Mt. Darwin, Tasmania, is described in detail. Two new analyses of this glass are given. Twenty-five published analyses of tectites are plotted on diagrams. J. F. SCHAIERER

**The natural etchings of Japanese pyrite crystals.** SHIMMATSU ICHIKAWA. *Am. J. Sci.* [5], 17, 245–57(1929).—The symmetry of the etch-figures corresponds to the hemihedrism of the crystals. As etching proceeds, pits with hemihedral arrangement develop, and the crystals pass through cubic and tetrahedral phases before complete soln. occurs. R. L. HERSHEY

**Crystal structure of sperrylite.** G. AMINOFF AND A. L. PARSONS. *Univ. of Toronto Studies, Geol. Series* No. 27, 5–10(1928).—Powder x-ray photographs of crystals and crystal fragments of sperrylite from the Vermilion mine, Sudbury, Ont., were compared with similar photographs of pyrite. The unit cube of edge 6.00 Å. U. contains 4 mols. with Pt at 4b and As at 8h, the type of structure being the same as in pyrite. The value 5.40 Å. U. was detd. for the cube edge of pyrite. J. W. SHIPLEY

**The occurrence of orthoclase and microcline in the Finnish granites and pegmatites.** P. ESKOLA. *Bull. comm. géol. Finlande* No. 85, 54–8(1929).—The K feldspar existing in the Archaean granites and pegmatites of Finland is almost always microcline; in the Rapakivi rocks it is usually orthoclase. Microcline can be converted into orthoclase by heating. Orthoclase can, however, be formed at very low temps. A. H. E.

**The structure of leucite and complex kaolinites.** MIŁCZYŚLAW DOMINIŁKIEWICZ. *Roczniki Chem.* 8, 542–52, German résumé 552–3(1928).—Leucite is interpreted as a deriv. of a kaolin anhydride. Its structure approaches that of orthoclase, both natrolite

radicals (cf. C. A. 22, 2341) of the kaolin nucleus being linked to potassium silicate nuclei so that the kaolin nucleus is not completely satd. The structural formula proposed for leucite accounts satisfactorily for all changes of the mineral. From the structural diagrams of andalusite, sillimanite and kyanite the structural isomerism is evident, which is in agreement with the stability of the individual members. These 3 minerals are assumed to be common kaolin aluminates. The possibility of the existence of an ordinary aluminum silicate differing from the mentioned minerals is discussed. The constitution of andalusite is analogous to that of topaz. The difference consists in  $\text{—Al=O}$  groups of the former being displaced by  $\text{—Al=F}$  groups in topaz, which is a kaolin fluo-aluminate. The same constitution must be ascribed to the tourmalines, in which B is linked to the aluminate side of the kaolin nucleus, that is, to the natrolite radicals. A total analogy is found between orthoclase and beryl. Both natrolite radicals of the kaolin nucleus in the 8 Al radicals are satd. with 8 Be-silicate radicals. Eucrase, a deriv. of beryl, is interpreted as a basic Be kaolinite. J. KUCERA

The iron of Sumampa and other pseudometeorites. E. HERRERO DUCLOUX. *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt. 1, 77–81(1928).—A supposed meteorite from Sumampa in Santiago del Estero was analyzed. Sp. gr. = 7.005, Fe 91.529–91.629, Mn 0.097–0.104, Sn traces, Ni none, P 0.640–0.655, S 0.098–0.137, C (total) 5.059–4.989, C (graphite) 4.766–4.585, C (combined) 0.293–0.404, Si-bearing residue 1.565–1.624%. The doubt about the meteoric origin was due to 2 earlier findings, that proved not to be meteorites. The first, from Atacama, weighed, 217.5 g. and had sp. gr. 7.909, AgCl 81.960, Ag metallic 17.218,  $\text{Fe}_2\text{O}_3$  0.520, Si-bearing residue 0.822, Se traces. The other specimen, from the Chaco de Santa Fé, weighed 182 g. and had sp. gr. 3.527; in the shell and the interior, resp., were found insol. in HCl 10.82, 8.09, loss at red heat 21.80, 21.80,  $\text{Fe}_2\text{O}_3$  61.90, 66.51,  $\text{Al}_2\text{O}_3$  3.90, 2.88,  $\text{TiO}_2$  0.33, 0.31, MnO 0.76, 0.59,  $\text{P}_2\text{O}_5$  0.12, 0.12,  $\text{SO}_3$ ,  $\text{SnO}_2$ , CaO, MgO traces. A. E. M.

New telluride occurrence in Quebec. ELLIS THOMSON. *Univ. Toronto Studies, Geol. Series No. 27*, 11–4(1928).—Ore from Montbray township, Que., was found to be rich in Te. Two types of ore occur, the first showing the genetic succession: pyrite, chalcopyrite and pyrrhotite, sphalerite, krennerite, tetradymite and altaite, petzite and coloradoite, native gold and chalcocite. In the second, krennerite is the predominating constituent, with considerable pyrite and chalcopyrite and minor amts. of Au, altaite, tetradymite, petzite, sphalerite, pyrrhotite and chalcocite. The 2 types grade into one another. J. W. SHIPLEY

Ores of the noble metals. F. BERNAUER. *Metallwirtschaft* 7, 411–3(1928).—Pt, Ru and perhaps Os occur chiefly in the "iron nucleus" of the earth; Au, Ag, Hg, Pd (with Pt and Ru in smaller amts.) in the sulfide zone; while in the silicate or outer zone are found only the residues of the noble metals left from the process of deposition. Lists of metal-bearing rocks, with localities, showing the mineral assocns. of greatest importance, are reported. Special emphasis is given to recent discoveries of Pt metals in S. Afr. W. C. EBAUGH

Bromine contents of Solikamsk carnallites. N. N. EFREMOV AND A. A. VESELOV-SKII. *Severokhim. J. Chem. Ind.* (Moscow) 5, 1365–9(1928); cf. C. A. 22, 3495.—The analysis of a sample of Solikamsk carnallite by 3 different methods has shown the presence of 0.17–0.30% Br, apparently chiefly in the form of  $\text{KCl.MgBr}_2.6\text{H}_2\text{O}$ . This compares with the av. Br contents of German carnallites, 0.20–0.35%. As the supply of Solikamsk carnallite is estd. at 11 billion tons, their total Br contents are about 22,000,000 tons. Industrially, this Br could be extd. with comparative ease. B. N.

Diatomaceous earth. E. V. ROZHKOVA. *Trans. Inst. Econ. Mineral. Met.* (Moscow) No. 42, 51–61(1929).—The compn. of 2 samples of the diatomaceous earth deposits near Mount Kamyshlov in the Urals is:  $\text{SiO}_2$  78.76, 75.59,  $\text{TiO}_2$  0.27, 0.93,  $\text{Al}_2\text{O}_3$  9.81, 10.57,  $\text{Fe}_2\text{O}_3$  3.15, 3.74, CaO 0.69, 1.05, MgO 1.72, 1.46,  $\text{K}_2\text{O}$  0.78, 0.56,  $\text{Na}_2\text{O}$  0.27, 0.54,  $\text{SO}_3$  0.11, 0.29, loss on ignition 4.70, 4.69%. BERNARD NELSON

Relation between the increase of the magnetic susceptibility of certain rocks when heated and the modifications occurring in certain of their mineral constituents. A. MICHEL-LEVY AND GASTON GRENET. *Compt. rend.* 188, 640–2(1929).—Expts. were made on this section of 8 different holocryst. and semicryst. rocks, which, for the most part, were poor in the ferromagnetic elements. In general the increase in magnetic susceptibility on heating was accompanied by the appearance of opaque regions in the parts containing chlorites. It is concluded that the increase in susceptibility is due to the formation of these dark regions, which are considered to be due to the dehydration of the chlorites or of the crystals of sphene in the inclusions. W. W. STIFLER

The role of pressure in rock crystallization. P. ESKOLA. *Bull. comm. géol. Finlande* No. 85, 77–88(1929).—A polemic. Increase of pressure has the same effect

as decrease of temp. High pressure keeps volatile substances in magmatic solns., lowering the temp. of crystn. and reducing the viscosity. The last stages of magmatic crystn. cause reactions identical with those of metamorphism, *i. e.*, formation of amphiboles at the expense of pyroxenes, epidote at the expense of anorthite, chlorite for biotite or pyroxene, etc.

ALDEN H. EMERY

A beryl-bearing pegmatite from Uuksu in Carelia, Finland. E. H. KRAUCK. *Bull. comm. géol. Finlande* No. 85, 70-7(1929).—The principal components are beryl, biotite, oligoclase and fluorite; K-feldspar, pyrite, epidote and calcite belong to a later stage; sericite and chlorite are alteration products. It is an unusual occurrence because of the lack of quartz.

ALDEN H. EMERY

An experiment regarding the composition of the binding substances of the mineral muds. E. S. BURKSER AND A. F. GORNSHTEIN. *Ukrainskii Khim. Zhur.* 1, Tech. Pt. 491-7(1925).—There are 2 types of mineral muds in Ukraine and the south of Russia: the black drift deposits in closed water basins, the black color of which is due to the presence of FeS, and gray muds of volcanic origin which have a low content of FeS. The muds contain 35-70% H<sub>2</sub>O. In 1889 Verigo established that the plasticity of the muds is due to the presence of the colloidal Fe compds. B. and G. give analyses of 11 muds and show that while the black muds contain about 1.0% by weight of inorganic colloids, the gray ones contain about 32%. A substance similar to the natural muds may be synthesized by mixing in proper proportions clay, sand and colloidal matter. R. M.

The bacteriogenous lime deposits. G. A. NADSON. *Arch. Hydrobiol.* 19, 154-64 (1928).—With reference to the studies of Dew and Molisch, N. points out that the phenomenon of the deposition of CaCO<sub>3</sub> by bacterial activity has been investigated by him in 1899-1903. A brief review is given of the expts. described in his Russian book "The Microorganisms as Geological Factors" I. (St. Petersburg, 1903). G. SCHWOCH

Determination of the quantity of C and constitutional water contained in the soils of the earth (AGAFOFF) 15. The recovery of Pt from dunite rock at Onverwacht, Transvaal (PRENTICE, MURDOCH) 9. Grinding apparatus for mineral substances (Fr. pat. 650,853) 1.

## 9—METALLURGY AND METALLOGRAPHY

D. J. DEMOREST, R. H. ABORN

Surface phenomena of small particles of minerals and flotation. KEN TAKAHASHI Hokkaido Imp. Univ. *Hokkaido J. Coal Mining* 169, 6-29(1928).—T.'s study of the charge of various minerals, flotation by means of oleic acid, the action of oleic acid, and the effect of the addn. of K xanthate, and saponin is described, the sample used being sulfides, sulfates and other minerals having the elec. charge of the same sign. *Results*.—The elec. properties of minerals cannot be considered to be the primary factor in the flotation process, although it may be important as a secondary factor. The action of oleic acid was examd. to test the state of adsorption and packing of the small particles, the degree of adsorption being measured by means of a stalagmometer, while the degree of packing was detd. by measuring the velocity of falling of the particles. The result shows that there is a marked difference of adsorption in quartz and other minerals, but the difference in adsorption capacity cannot be considered to be directly responsible for the success or failure of flotation. The effect of oleic acid on the packing of the minerals with different samples varies, the effect being of 3 classes: it was the most marked in the first group, intermediate in the second and very poor in the

third. The result of the flotation test is quite similar, there being 3 different degrees of sepn. By adding xanthate the packing effect of the oleic acid is augmented in galena, pyrite and copper pyrite, and particularly in the second, the effect being roughly proportional to the amt. of xanthate adsorbed. Excess of the reagent decreases the effect. The effect is not remarkable in  $\text{BaSO}_4$ . The effect of saponin is to retard the packing effect of oleic acid, except in  $\text{ZnS}$  and  $\text{BaSO}_4$ , the retardation being proportional to the amt. of the reagent added, although the packing effect is augmented by a large excess. In  $\text{ZnS}$  and  $\text{BaSO}_4$ , saponin has the effect of increasing the speed of settling, but the effect is not very remarkable. Generally speaking, within certain limits  $\text{K}$  xanthate accelerates, and saponin retards the packing caused by oleic acid. This effect is the same as in that of saponin and  $\text{K}$  xanthate upon the degree of flotation of minerals, so that there seems to be a close relation between packing and flotation. K. S.

**Calculations in ore dressing.** W. LUYKEN AND E. BIERBRAUER. *Am. Inst. Mining Met. Eng. Tech. Pub. No. 214*, 25 pp. (1929).—An attempt to show that a sure, complete and successful way to overcome existing difficulties has been found to deal with the calcns. in ore dressing. Enrichment operations are compared on the basis of their abs. or of their economic effect. Characteristics of enrichment are indicated graphically, also curves of equal efficiency. W. H. BOYNTON

**Flotation, a field for chemical work.** RICHARD SCHÖN. *Oesterr. Chem.-Ztg.* **32**, 53 6, 64-7 (1929).—A lecture covering the history, economic importance, methods and "variables" influencing the flotation method for concg. ores. The "variables" include (1) the ore substances (gang and mineral) themselves, (2) oils or org. reagents employed, (3) the nature of the ore-water-oil mixt. itself, (4) the kind of gas used for agitation and (5) the type of app. adopted. The far different economic conditions of Europe account for the fact that flotation lags far behind America, Australia and Africa in tonnages treated by flotation. W. C. EBAUGH

**Flotation separation tests.** BERNARD W. HOLMAN. *Mining Mag.* **39**, 151-61 (1928).—App. and general principles of testing ores by flotation are discussed. A. B.

**Selective flotation in Spain.** L. BARCENA DIAZ. *Eng. Mining J.* **127**, 640-2 (1929). H. C. PARISH

**Development of copper ore leaching in Arizona.** RUDOLF GAHL. *Eng. Mining J.* **127**, 636-9 (1929).—G. concludes that to obtain the best results from a sand leaching plant a decantation plant should be operated in connection with it. If a decantation process is relied upon for treatment of slime it will almost certainly pay, in the treatment of  $\text{Cu}$  ores contg. part of the  $\text{Cu}$  as sulfide, to give the slime a preliminary flotation treatment. H. C. PARISH

**The limitations of the Harris process.** FRIEDRICH VOGEL. *Metallborse* **18**, 1882-3, 2105-6 (1928).—The Harris process consists in refining pig lead by fusion with a mixt. of  $\text{NaOH}$ ,  $\text{NaCl}$  and  $\text{NaNO}_3$ . The reactions are:  $\text{Sn} + \text{Na}_2\text{O} + 2\text{PbO} = \text{Na}_2\text{SnO}_3 + 2\text{Pb}$ ;  $\text{Sb} + \text{Na}_2\text{O} + 2\text{PbO} = \text{Na}_2\text{SbO}_3 + 2\text{Pb}$ ;  $2\text{As} + 3\text{Na}_2\text{O} + 5\text{PbO} = 2\text{Na}_3\text{AsO}_4 + 5\text{Pb}$ . Large amts. of these salts are formed during purification and their disposal is sometimes difficult. E. M. SYMMES

**The Bessemer works of Sweden.** J. A. LEFFLER. *Jernkontorets Ann.* **82**, 545-48 (1927).—A statistical historical survey. A. DROGSETH

**The sintering plant of Spännarhyttan.** J. A. LEFFLER. *Jernkontorets Ann.* **82**, 569-76 (1927).—A description accompanied by drawings is given of the sintering plant of the Swedish iron works of Spännarhyttan. A. DROGSETH

**Sinter plant at Messrs. Guest, Keen and Nettlefolds, Ltd., Cardiff Works.** W. E. SIMONS. *Engineering* **127**, 560-2 (1929); *J. Iron and Steel Inst.* (advance copy) No. 14, May, 1929, 14 pp.—From 16 to 25% of the ore burden consists of sintered  $\text{Fe}$  ore. The sintering consists of mixing fine  $\text{Fe}$  ore, coke and flue dust, placing in a circular steel pan and igniting by means of oil burners, a motor-driven fan drawing air through the pan. The materials are mixed dry and the mixt. is wetted by a fine spray of water till it contains about 15% of water. Lime should be absent. Sprinkling a small quantity of anthracite or coke breeze on the top of the pan prior to ignition insures good ignition and reduces the fines to a min. Burnt pyrite ores require more coke than do hematites and magnetites. The sinter mixt. should not contain more than 30% of flue dust. Flue dust should be stacked in the open for months before use in the blast furnace. Typical operating data are given. W. H. BOYNTON

**Sintering of powdered substances.** J. ARVID HEDVALL AND E. HELIN. *Jernkontorets Ann.* **82**, 265-342 (1927).—High sintering temp., small size of grain and irregular shape of grain give high strength. Expts. with reduction of pure  $\text{Fe}_2\text{O}_3$  preps. by gas contg.  $\text{CO}$ , giving a mixing of  $\text{Fe}_3\text{O}_4$  and  $\text{Fe}_2\text{O}_3$ , gave higher shrinkage and strength. By subsequent oxidation through cooling in air, shrinkage and strength are further

raised. Expts. with oxidation of pure  $\text{Fe}_3\text{O}_4$ , and magnetite showed complicated relations. The intensity of the oxidation  $2\text{Fe}_3\text{O}_4 + \frac{1}{2}\text{O}_2 = 3\text{Fe}_2\text{O}_3$  principally depts. whether strength is increased or decreased. To produce sufficiently strong briquets the intensity must not exceed certain limits. Addn. of (1) 4.3%  $\text{SiO}_2$  to pure  $\text{Fe}_3\text{O}_4$ , (2) 5%  $\text{SiO}_2$  to  $\text{Fe}_3\text{O}_4$ , and (3) 5%  $\text{CaO}$  to  $\text{Fe}_3\text{O}_4$ , raised the strength on sintering. Simultaneous addn. of 5%  $\text{CaO}$  and 5%  $\text{SiO}_2$  to  $\text{Fe}_3\text{O}_4$  was on the contrary not advantageous to the strength.

A. DROGSETH

Utilization and working up of metallic ashes and residues. RICH. GRAUBNER. *Chem.-Ztg.* 53, 307-8(1929).—Metallic ashes are "rich" if they carry 50-80% of metal, and "poor" if the metal content is less than 50%. Such materials are sorted, sifted, mixed in proper proportions to give the pure metal or alloy desired, smelted in a reverberatory furnace with fluxes to yield a slag of low m. p., and then poured and used as an alloy like soft solder or type metal, or refined by the addn. of S,  $\text{Sb}_2\text{S}_3$ , etc., to make mat of the Fe present and yield purer metal. Pb slag is sometimes used in the charge of glass works; Sn slags are smelted with Pb charge and the Sn is recovered in the solder produced.

W. C. EBAUGH

Onverwacht platinum metallurgy. T. K. PRENTICE AND R. MURDOCH. S. African Min. and Eng. J. 39, 565-7(1929).—Treatment of concentrates is by an amalgamation process, with Zn amalgam,  $\text{CuSO}_4$  and  $\text{H}_2\text{SO}_4$  as the activating reagents (cf. Zachert, C. A. 14, 2517). Row sheets of original concn. and treatment plants are given and described and tabular data are included on milling and treatment process results. Cf. following abstr.

E. I. S.

The recovery of platinum from dunite rock at Onverwacht, Transvaal. T. K. PRENTICE AND R. MURDOCH. *J. Chem. Met. Mining Soc. S. Africa* 29, 157-67(1929).—Pt occurs as a primary constituent of hortonolite dunite segregations (sp. gr. 3.7-3.9) within larger bodies of olivine dunite. Its av. compn. is hortonolite 93.2, diopside 5.0, hornblende 1.5, chromite 0.25 and magnetite 0.05%. The rock is regularly jointed, the joints (4 in. wide) being filled with magnesite. The Pt occurs in cubes or irregular nuggets enclosed in the hortonolite or in contact with the chromite (highest assay values). The metal shows the following compns. from the surface and 200 ft. deep, resp.: Pt 84.0, 84.75, Os-Ir 2.3, 0.95, Rh 0.2, tr., Pd 0.3, 0.53, Cu tr., 1.28, Ni —, 0.48, Fe 12.8, 11.98%. Details of the early lab. concn. tests, pilot plant and final large-scale installation and results achieved are given together with numerous flow sheets. Cf. preceding abstr.

**A new method for the production of sound steel.** CHARLES PARSONS AND H. M. DUNCAN. Newcastle-upon-Tyne, England. *J. Iron and Steel Inst.* (advance copy) No. 10, May, 1929, 12 pp.; *Engineering* 127, 623-4.—A short and thick ingot-mold is described with a large chill-block for its base, thick refractory walls, and gas or oil burners inserted through the cover to retard the freezing of the top of the ingot. A mild-steel ingot 45 in. high, 70 in. in diam., weighing 20.5 tons, was cast in this mold; the macrostructure and elem. analyses showed absence of segregation except near the top edge. The mech. properties and microstructure of some parts of the ingot were poor on account of streaks of inclusions. More rapid pouring, to cover the bottom of the mold more quickly, would probably avoid this trouble, and it was not found in a smaller ingot poured with the same-sized nozzle. S prints and macrographs show less irregularity of compn. than in ordinary ingots. Numerous illustrations of the structure are given. The importance of avoiding segregation is emphasized. **GEO. F. COMSTOCK**

**The coalescence of non-metallic inclusions in steel.** C. H. HERTY, JR. U. S. Bur. Mines Expt. Sta., Pittsburgh, Pa. *Proc. Eng. Soc. West. Penn.* 44, 259-67 (1928).—Non-metallic inclusions in steel may come from dirt in the pig Fe or scrap charged, but are mostly derived from deoxidizers. Various types of inclusions are illustrated. Deoxidation by Mn produced gray slag inclusions; by Si, glassy globules; by Ti and Si, inclusions showing duplex structure; and by Al, fine specks grouped but not coalescing. Coalescence facilitates elimination of inclusions, and a low m. p. promotes coalescence. Al generally raises the m. p. of inclusions, but some combination of elements in a deoxidizer may be found to remove this disadvantage. The connection of inclusions with banded structure was brought out in the discussion. **GEO. F. COMSTOCK**

**Use and development of magnetic analysis in the United States.** A. V. DE FOREST. Am Chain Co., Bridgeport, Conn. *Intern. Congress Testing Materials* 1927, I, 489-500.—“Magnetic analysis” means detg. phys. and mech. properties from magnetic measurements, and thus implies more than mere magnetic testing. Useful relationships between mech. and magnetic properties have often been found with other conditions const., but the relation may be entirely changed by slight differences in compn., strain, or heat treatment. Permeability tests have been used to detect flaws in rods, wires, etc. The progress of the work of an Am. Soc. Testing Materials comm. on magnetic analysis of high-speed steel drills is described; this work makes it possible to recognize the effect of the quenching, or the drawing temp., separately, from magnetic detns. of permeability and watt loss. By means of the cathode ray oscillograph a diagram may be obtained for each specimen from which peculiarities of analysis, working, quenching, and drawing may be separately recognized by comparison with a predetd. standard. This method, using an a. c. bridge to measure loss and induction, has been applied to routine com. testing of case-hardened chain links for brittleness. Changes in reluctance of a d. c. magnetic circuit have been used to det. the uniformity of turbine rotor disks. The Duroscope, tests of wire rope, and checking the quality of specimens to be used for long high-temp. tests are other applications of magnetic analysis. In discussion, D. Lewis of Sheffield described a rapid com. magnetic test for controlling the heat treatment of small steel parts, involving a detn. of coercivity which was closely related to the Brinell hardness. A bibliography of the subject is | **Also in Iron Age** 122, 1573-4. **GEO. F. COMSTOCK**

Some observations on melting of steel. VILHELM LOF. *Jernkontorets Ann.* 82, 257-62(1927).—The paper gives a survey of the decarburizing process. The presence of O and CO in the melted iron was confirmed. L. assumes that killing of iron with Si and Al is caused by disocn. of oxides and CO. Hot brittleness of Fe was examd. and is believed to be caused by oxides dissolved in the Fe.

Autogenous and electrical welding in steel and iron foundries. H. NEESE. *Gieserei Ztg.* 26, 209-16(1929).—Movable and stationary gas welding app. for foundries, gas and arc welding for cast steel and gray cast iron, cold welding, hot welding and the cost of gas and electricity for welding are discussed.

A contribution to the study of the action of gases on metals. I. Kinetic study of the phenomena. G. VALENSI. *J. chim. phys.* 26, 152-77(1929).—Gases evolved by Fe, Cr and Mn on heating were measured and analyzed. Metals prepd. by reduction in an elec. furnace evolve more gas than metals prepd. by the thermite process. The absorption of  $N_2$  at a pressure of 760 mm. by Mn and Cr was also measured at 610°, 800° and 1000°. The results are given in the form of graphs. The amt. of  $N_2$  absorbed by Cr agrees best with the formula  $CrN$  while for Mn the formation of the compd.  $Mn_3N_2$  is the most probable.

The oxidation of iron and steel at high temperatures. L. B. PFEL. *J. Iron and Steel Inst.* (advance copy) No. 11, May, 1929, 47 pp.—When steel is oxidized at red heat in air, scale is formed in 3 layers. The outer 10% is often cracked, with a conchoidal fracture, and is sepd. from the middle 50% by a surface of "bright lightly etched appearance." The middle layer is similar, and shows on its inner surface all details of the original surface of the steel. The inner 40% is very weak, porous and cryst. The outer layer is mainly  $Fe_2O_3$ , and the others are richer in FeO, but none is uniform in compn. Oxidation probably proceeds by diffusion of O inward, and of Fe outward, through the solid solns. constituting the scale. When samples of scale were heated in N or in *vacuo* in the same furnace, if the av. Fe content was over 72%, the O became evenly distributed; but scale contg. 72% Fe did not react with scale lower in Fe. The solid solns. are therefore continuous from FeO to 72% Fe, but a second soln. must exist with less Fe. This is the soln. found in the outer layer, which contains less than 72% Fe. Similar results were obtained on heating Fe with scale, showing that the Fe concn. in scale may increase without direct soln. Scale grows both inward and outward from the original surface. The inner layer is porous because the velocity of outward diffusion of Fe is greater than the rate of oxidation of the Fe core. In scaling alloy steels, the alloying element was concd. in the inner scale layer, except with Mn, and this layer had the same outside dimensions as the original steel. This layer on Ni steel contained metallic globules of Ni, and the steel below the scale showed oxide inclusions. Mn was highest in the middle layer of the scale. MnO is evidently sol. in the Fe-rich oxide soln., while with the other alloys, only the Fe diffuses readily through the scale. The effect of increased time of oxidation was similar to that of a faster rate. Heating of Fe in  $CO_2$ , steam, or with  $Fe_2O_3$ , NiO, CuO or Cu produced cryst. scale. These formations are explained on the theory that Fe diffuses outward through the scale, causing growth of the crystals of the high-Fe (cubic) oxide soln., while the high-O (hexagonal) phase does not occur in the coarse-grained form.

Constitutional diagrams for cast irons and quenched steels. A. L. NORBURY. Cast Iron Research Assn., Birmingham, England. *J. Iron and Steel Inst.* (advance copy) No. 9, May, 1929, 26 pp.—Two distinct types of gray cast Fe are described, similar in chem. compn. and conditions of casting, but having different forms of graphite because of melting conditions. One type contains "supercooled" or fine graphite usually in a ferrite matrix, with a fine sooty fracture; the other type has normal, coarse graphite flakes, in pearlite, with a coarser steel-gray fracture, and inferior chilling tendency. Constitutional diagrams for normal and supercooled cast Fe contg. O, 2 and 4% Si, resp., are shown, similar to those for normal and modified Al-Si alloys, and are discussed in detail. The data used in constructing these diagrams were taken from previous literature. The eutectic temp. is raised by Si, and its C content lowered, and the Fe-C eutectoid is affected in the same way by Si. Less than 2% Si suppresses  $\gamma$  Fe in the absence of C, but with even a small quantity of C, the allotropic transformations are merely brought a little closer together by even 4% Si. When graphite nuclei are destroyed in the melt by superheating, the supercooled structure is obtained, with numerous fine graphite flakes and less combined C. A similar discussion and diagram are given for quenched steel, representing the lowering of the change points as a form of supercooling. Troostite is pearlite refined by supercooling. The solid soly. of C in  $\gamma$  Fe is 0.6% at 350°. Also in *Foundry Trade J.* 40, 375-8, 397-9(1929).

Heat treatment and volume changes of gray cast iron between 15° and 600°.

W. DONALDSON, *Foundry Trade J.* 39, 299-303, 315-8(1928).—Various types were subjected to heat treatments for 200 hrs. at temps. of 450° and 550°, and the influence of such heat treatment on the combined C, tensile strength and hardness was detd. With a total C content from 3.1 to 3.3% there is little change in the heat-resisting properties, but with a further increase in C content there is a tendency to increased decompn., while with a decrease there is a very marked increase in stability. Increasing the Mn content increases the stability uniformly. P exerts a slight stabilizing effect. Si has a noticeable effect on the heat-resisting properties. With 1.10% stability is marked and increases slowly as the Si decreases. Over 1.2% Si stability is greatly reduced and diminishes rapidly as Si increases. The microstructure of the various changes is given in detail and substantiates the results obtained. The vol. changes were detd. by direct or dilatometric measurements. These changes are due to the decompn. of the combined C followed by air penetration along the graphite plates causing oxidation of the Fe. J. W. BOECK

Chain steel requires special qualities. JOSEPH R. MILLER. *Iron Age* 123, 1205 (1929).—Chain steel contains C 0.09%, Mn 0.32-0.45%, P 0.025% and S 0.045%. P and S must not go above these limits for the best welding properties. The steel should be free of oxides and inclusions which favor oxidation of the metal at welding temps. and should contain no Si and As. C. H. LORIG

Influence of forging temperature and heat treatment on strength of forged steel axes. G. L. EKKLUND. *Jernkontorets Ann.* 82, 577-608(1927).—Two steels (0.37% C and 0.56% C) were investigated. Both were forged in 2 temp. ranges (a) 1200-925° and (b) 850-725°. The following heat treatments were tried: (a) normalizing, (b) annealing from normalizing temp., (c) annealing at 670°. The results of the tests show that low finishing temp. gives higher strength. By correctly executed normalization the structure is improved (the difference between periphery and center diminished), and the strength is raised. A. DROGSETH

The microstructure of rapidly cooled steel. J. M. ROBERTSON. Royal School of Mines, London. *J. Iron and Steel Inst.* (advance copy) No. 12, May, 1929, 29 pp.—The microstructures produced in rods of 0.75% C steel, 0.11 in. in diam., by quenching in molten metal at temps. between 600° and 220° are illustrated and described. With very slow cooling in the furnace, each austenite grain changed into pearlite uniformly oriented, but with more rapid furnace-cooling, several orientations of the pearlite appeared in each grain. A fan-shaped arrangement of pearlite laminations was characteristic of still more rapid cooling as in air or in molten metal between 620° and 440°, the fineness of the laminations and of the fans increasing with the speed of cooling. As the temp. of the quenching medium decreased, the laminations became invisible, and the pattern acicular, until at 320° or below martensitic structures were found. The fan structure was sometimes found mixed with any gradation of the other structure. The former arises at the Ar' point, and the latter at the Ar'' point. The discontinuity in crystal form is due to the fact that for a given increase in rate of cooling, the allotropic change in Fe, which is Ar'', is lowered more than the formation of cementite, or Ar', and at a certain rate the latter may be suppressed, but not the former. The manner in which the change is initiated governs the crystal form of the product. The Widmanstätten or true crystal habit of  $\alpha$ -Fe is observed when complete diffusion of C can occur, or when rapid cooling prevents any diffusion. GEO. F. COMSTOCK

The transformation of austenite into martensite in an 0.8 per cent carbon steel. DARTREY LEWIS. Am. Chain Co., Bridgeport, Conn. *J. Iron and Steel Inst.* (advance copy) No. 7, May, 1929, 11 pp.—Cold-drawn wire, 0.192 in. in diam., contg. 0.79% C, 0.45% Mn, 0.22% Si and small quantities of impurities, was heated to 816° and quenched in fused salt, or in salt followed by oil, at various temps. Dilatation and magnetic tests were made on the samples during air-cooling after the quench. Quenching in salt at 232° to 177° produced austenite, which changed to martensite after air-cooling a few min. With the salt at 149°, most of the martensitic change was completed in the salt, and with the temp. below 94°, all of it was completed in quenching. Quenching in salt above 260° produced austenite which was less stable, and 5 mins. in the quenching bath caused a change to a needle-like structure of low hardness. With the salt at 343° or above, no austenite was retained, and the product of the quench was sorbitic. Holding the specimen in salt at 205° for 15 mins. after the quench did not cause the martensitic change to progress any further than holding for 1/3 min. Rockwell hardness of C-59 was obtained by decompn. of austenite below 232°, but when quenched in salt at higher temps. the air-cooled specimens were correspondingly softer. The microstructures are illustrated. A two stage hardening of this kind is readily controlled with accuracy, and may have practical use in avoiding distortion, or to permit forming in the austenitic state. GEO. F. COMSTOCK

**X-ray study of hardened carbon steel.** G. KURDYUMOV AND E. KAMINSKII. *Z. Physik* 53, 696-707(1929); cf. *C. A.* 22, 4430.—The influence of C content upon the axial ratio and upon the parameters of the tetragonal lattice is studied. By removing the surface of the sample in steps it is shown that the tetragonal structure exists not only on the surface of the hardened samples but also in the interior, contrary to the statements of Honda and Sekito (*C. A.* 22, 4430). The change of structure after annealing at 100° has been studied. From the x-ray diagrams it is possible to get some idea how the tetragonal structure is destroyed.

GEORGE GLOCKLER

**The austenite domain in chromium alloyed steels.** BO KALLING. *Jernkontoret's Ann.* 82, 609-67(1927).—The paper gives the results of microscopic and hardness examns. after different heat treatments of Cr steels with 0 to about 30% Cr, and with, in general, low C contents. For steels with Cr < 5% the following etch reagent has been used with good results: 5 g. CuCl<sub>2</sub>, 100 cc. HCl (1.19), 100 cc. alc. and 100 cc. water. The content of CuCl<sub>2</sub> has been varied. The results show that the formation of austenite ceases at a certain Cr content, which has been detd. for different C contents. With 0.25% C the formation of austenite ceases at about 25% Cr, and with 1.0% C at about 30% Cr. Under certain relations only a part of the ferrite is transformed to austenite. These relations have been examd. and the results show that the equil. diagram for Cr > 10% is of a completely different character than the ordinary C-steel diagram. The pearlite eutectoid is replaced by the so-called limit of satn. Carbide is not sol. in the Cr-ferrite under about 1200°; with higher temps. there seems to be a certain soly. which does not exceed about 0.10%. The compn. of the carbide has been examd. The results show that the carbide has a nearly const. compn. in steels from 13 to 30% Cr. The analysis is: C 5.3-5.4%, Cr about 63%. Equil. diagrams are given for 5, 10 and 13% Cr. With higher Cr content a 3-dimensional diagram is necessary.

**Copper alloys.** I. Copper-bismuth. II. Copper-arsenic. III. Copper-phosphorus. IV. Copper-oxygen. V. Copper-antimony. VI. Copper-lead. FRIEDRICH FRÉUDE. *Metallbörse* 18, 818, 874-5, 1043-4, 1099, 1379(1928); cf. *C. A.* 21, 1616. P. presents data indicating the effect of small quantities of Bi, As, O, Sb and Pb on the mech. and elec. properties of Cu. 0.02% Bi in Cu causes appreciable hot-shortness. When 0.05% Bi is present Cu becomes cold-short and shows pronounced hot-shortness. Cu contg. not more than 0.1% Bi can be rolled when 0.6% As is introduced in the alloy. With more than 0.005% Bi Cu is unsuitable for wire drawing. With more than 1% As in Cu the metal becomes red-short. Cu contg. both O (0.4%) and As (0.5%) is hard and cold-short. The elec. cond. is reduced to 87.2% for a content of 2.57% As. Addn of 0.6% As to Cu contg. small quantities (0.1% or less) of Bi, Pb, Sb, or S improves the metal noticeably. P dissolves in Cu up to 0.2%. From 0.2 to 8.2% P the alloy consists of primary Cu grains and a eutectic of Cu + Cu<sub>3</sub>P. Both hardness and tensile strength are greatly increased by the addn. of P. O present in Cu as Cu<sub>2</sub>O tends to make the Cu cold-short. It is particularly harmful where the metal is exposed at high temps. to reducing gases. With 1% Sb in Cu the metal is markedly red-short. 0.6% Sb in Cu reduces the elec. cond. to 57.6%. Cu free from O cannot be hot-rolled when it contains 0.02% Pb. When O is present Pb is harmless up to a content of 0.15%. In the latter case hot-shortness becomes pronounced for a Pb content of 0.3%.

**Recent investigations on the thermal aging of light alloys.** P. SCHWERBER. *Metallbörse* 18, 873-4, 985-6, 1098-9(1928); cf. *C. A.* 20, 2141.—A crit. review of the thermal aging of duralumin and related alloys, summarized in the following conclusions: (1) the constituents which cause self-hardening form solid solns. with Al; (2) the solid soly. varies with the temp.; (3) the possibility of hardening depends particularly on the sepn. of a compd. from the solid soln.; and (4) the amt. of the addnl. constituents should be between the limits of solid soln. at high temp. and at room temp. Al alloys free from Mg (such as aeron) age at room temp. just like duralumin when the ever-present Si is re-

moved as insol.  $\text{CaSi}_2$  by the addn. of Ca. Duralumin made with pure Al (contg. only 0.03% Fe and 0.02% Si) age-hardens as well as the usual product which contains Si in the form of  $\text{Mg}_2\text{Si}$ . Systematic investigations by S. since 1926 led to the manuf. of an improved duralumin with a strength 25-30% above that of the usual material.

Passivity of metals and its relation to problems of corrosion. ULICK R. EVANS. *Am. Inst. Mining Met. Eng., Tech. Publ.* No. 205, 23 pp. (1929).—Passivity of metals is due to a protective film which is the product of direct reaction of the metal with  $\text{O}_2$ . Passivity can also be brought about by anodic oxidation at high c. ds. The film is insol. in concd.  $\text{HNO}_3$  at ordinary temps. and is therefore believed to be  $\text{Fe}_2\text{O}_3$ . Cl ions, inclusions at phase junctions, and abrasion marks tend to weaken or penetrate the film, thus restoring part of the metal to the active state. Passivity can be brought about in the process of anodic soln. in acids at high c. ds. since at the instant before passivity sets in the liquid film adjacent to the metal (due to the formation of neutral or basic salts) is incapable of dissolving the film. Methods of isolating the film are described. The film is transparent, shows emery marks and is less than 400 A.U. thick. The function of  $\text{O}_2$  in an aq. corrosion process is to divert the attack to regions of lower  $\text{O}_2$  concn. Rust is not the direct reaction product but is a ppt. formed by secondary reactions. Rusting takes place at points in which there is a break in the film which is the direct reaction product. Carbonates and phosphates retard corrosion because of the formation of insol. direct reaction products at the anode while  $\text{Ca}(\text{OH})_2$  and  $\text{Mg}(\text{OH})_2$  prevent it by forming insol. products at the cathode. B. E. ROETHLI

Observations on the corrosion of iron. J. F. G. HICKS. *J. Phys. Chem.* 33, 780-90(1929).—The corrosion of Fe was studied and the effects of  $\text{H}_2\text{O}$ ,  $\text{O}_2$  and  $\text{CO}_2$  were detd. Consideration of the soly. of the various factors involved gave the following results. The primary cause of the corrosion of Fe is attributed to the soln. of Fe in  $\text{H}_2\text{O}$ . A film of  $\text{H}_2\text{O}$  adhering to the metal surface undergoing corrosion is necessary to this dissolving process.  $\text{O}_2$  produces the max. e. m. f. with respect to dissolving Fe and acts as an accelerator; it removes  $\text{Fe}(\text{OH})_2$  and  $\text{H}_2$  by oxidation and is hence a maintenance factor in the corrosion process.  $\text{CO}_2$  is also a maintenance factor because of the removal of  $\text{Fe}(\text{OH})_2$  and it accelerates the reaction by decreasing the  $p_{\text{H}}$ . B. E. ROETHLI

Corrosion phenomena on irons and steels. E. SCHREIBER. *Metallbörse* 18, 2274-75(1928).—A summary of various methods for corrosion prevention such as, oxide film formation, plating, tempering, oiling, lacquering, wrapping in paper or sawdust, etc. The importance of removing acids, bases or salts from the surface of the metal prior to oiling and of having a neutral oil (free from fatty acids) is emphasized. Sawdust should be dry and paper or wood should be free from alk. earth chlorides. B. E. ROETHLI

The corrosion of steel by acid solutions. HIROZÔ ENDÔ. *Science Repts. Tôhoku Imp. Univ.* [1], 17, 1245-63(1928).—See C. A. 23, 1858. DOWNS SCHAFF

Corrosion—a problem in protective coatings. F. N. SPELLER. *Ind. Eng. Chem.* 21, 506-10(1929); cf. C. A. 23, 2410.—A review of the corrosion situation showing the variety of ways in which protective films come into play in corrosion prevention. Conclusion: Corrosion is detd. and controlled by influences, external to the metal which tend to form or destroy surface films; protective films form more readily in air than in  $\text{H}_2\text{O}$ ; in soils or  $\text{H}_2\text{O}$  wrought iron and steel corrode to about the same extent; a Cu

content greater than 0.15% increases the resistivity of films formed in air; when expense and external conditions warrant their use metals forming highly resistant films should be used.

**Electrical resistance method of measuring corrosion of lead by acid vapors.** R. M. BURNS AND W. E. CAMPBELL. *Trans. Am. Electrochem. Soc.* 55 (preprint) 14 pp.(1929) — A method is developed for measuring the rate of corrosion of a metal, in terms of the rate of increase in resistance of a wire as it is reduced in cross section by the progress of corrosion. The reproducibility of the method is tested by running duplicate tests in the same corrosive atm. For these tests extruded Pb wire, 0.213 mm. in diam., is used and the corrosive media are atms. in equil. with concns. of AcOH ranging from 0.00001 *M* to 0.02 *M*. The resistance change-time curves are reproducible to within 15%. The method is applied to the problem of comparing the corrosiveness of different wood sawdusts, and results are obtained which correlate closely with lab. tests on wood acidity and with field experience. Illustrations of the use of the method for following a change in corrosive atm., and for comparing the behavior of different alloys exposed to the same atm., are given.

C. G. F.

**The causes of grate-bar destruction and appropriate preventive measures.** K. HOFER. *Glückauf* 64, 211-5(1928).—Temp., atm. O, contact with ash or slag, and perhaps electrolytic action too, may be taken as the chief causes for the destruction of grate bars. The nature of the metal of the bar itself, especially with respect to the graphite content, causes differences in the resistance, as the C burns out and then oxidation penetrates through the spaces so left. A dense grate bar, especially on the surface, is recommended. Cooling of the grate bars is indicated as a preventive of corrosion. Low S content of coal is also desirable. Cooling may be effected by giving sufficient depth to the bar, by exposing larger surfaces to the cooling air, steam or atomized water, etc., or by having the ash itself cool before it reaches the grate. Addnl. protection is afforded by chrome plating and other O-resistant surface treatments.

The mat is disintegrated by exposure to a moist atm. An alkali-contg. compd. is added to the disintegrated mat, the mixt. is roasted at 600°, leached (weak acids, brine or solns. of ammonia compds. may be used as solvents if required but hot water is usually sufficient to dissolve the sulfates) to remove sol. constituents, and the leached residue is subjected to gravity sepn. to conc. the precious metal values.

**Metals from ores.** FERDINAND DIETZSCH. Fr. 648,742, Nov. 25, 1927. Oxide, oxidized or roasted ores are treated with a soln. of thiosulfate simultaneously with, or after, treatment with a soln. of  $\text{SO}_2$ , to ext. Cu or Pb and Zn or Ag. Solns. of cuprous sulfite and Pb sulfite or sulfate are formed. The metals are pptd. by adding a sulfide, polysulfide, carbonate, hydroxide or oxide of an alkali or alk. earth metal and the thio-sulfate formed is used again.  $\text{H}_2\text{S}$  may be used to ppt. the metals, in which case the thiosulfate is regenerated by heating with lime and  $\text{H}_2\text{SO}_4$  and  $\text{Na}_2\text{SO}_4$ . Examples are given of the treatment of an oxidized Cu ore and a roasted Pb-Zn-Ag ore.

**Direct reduction of iron from its ores.** SAMUEL L. MADORSKY (to Gathmays Research Corp.). U. S. 1,711,738, May 7. In order to effect a fractional reduction of Fe oxide ores contg. Ti oxide, a reducing gas such as H is passed through the oxide in molten form and the temp. of the mass is maintained above its m. p. and the reducing gas in contact with the molten material is maintained substantially free of C and N. An app. is described.

**Treatment of sulfide ores.** FRIEDRICH JOHANNSEN. Ger. 475,115, May 31, 1924. Sulfide ores and like metallurgical products contg. volatilizable metals are mixed with a reducing agent, e. g., coke, and heated so as to generate metal vapors which are oxidized either in the heating furnace or outside. The reducing agent is added in sufficient amt. to avoid oxidation of the S and to maintain a reducing atm. in the vicinity of the charge in the reaction zone. Alk. earth compds., if not already present, are added also in sufficient amt. to fix the S.

**Treatment of antimony, arsenic and mercury ores.** OESTERREICHISCHE BAMAG-BUTTNER-WERKE A.-G. and RUDOLF JAHN. Ger. 475,387, Feb. 10, 1926. The powd. ore is passed through a heated rotary tube, preferably of cruciform section, in the same direction as a stream of air, and the oxide fumes so obtained are passed into a separator for solid impurities maintained at such a temp. that the fumes are not condensed. The fumes are then blown into a heated chamber in which they are reduced by powd. C or by gases such as CO or H. The reduction may also be effected by mixing the fumes with the gases and blowing the mixt. through an elec. arc.

**Treatment of metals.** CHARLES BOURGEOIS. Swiss 127,588, May 23, 1927. Small metal objects such as parts of clocks are heated in a reducing atm. such as  $\text{CO}_2$ , HCN or  $\text{C}_2\text{H}_2$  to prevent the formation of oxide, and to remove oxide films already present.

**Deoxidizing molten metals.** SIEMENS & HALSKE A.-G. Fr. 650,380, Mar. 3, 1928. See Brit. 288,543 (C. A. 23, 593).

**Recovery of zinc, etc., from iron-bearing materials.** F. KRUPP GRUSONWERK A.-G. Brit. 299,300, Oct. 22, 1927. In effecting recovery of Zn or other volatilizable metals from materials such as waste pyrites (as by the process described in Brit. 225,842; C. A. 19, 1553) the material is mixed with excess (not less than 45%) of fuel and treated in a rotary furnace so as to avoid deposits of iron in the furnace.

**Reducing zinc-bearing materials.** FRANK G. BREYER and EARL H. BUNCE (to New Jersey Zinc Co.). U. S. 1,712,134, May 7. See Fr. 639,972 (C. A. 23, 808).

**Reducing zinc-bearing materials.** FRANK G. BREYER and EARL H. BUNCE (to New Jersey Zinc Co.). U. S. 1,712,132, May 7. Agglomerates of Zn silicate ore or other suitable Zn-bearing material and carbonaceous material are progressively passed through a reducing chamber such as a vertical retort without breaking down the agglomerates and the latter are heated sufficiently to effect reduction of Zn compds. and volatilization of metallic Zn without slagging or fusing of the agglomerated charge; Zn vapor may be withdrawn and directly condensed to Zn metal. An app. is described.

**Condenser for zinc vapor.** FRANK G. BREYER (to New Jersey Zinc Co.). U. S. 1,712,133, May 7. See Fr. 638,619 (C. A. 23, 368).

**Zinc from zinc oxide.** CHRISTIANUS J. G. AARTS. U. S. 1,712,641, May 14. C is added to a fused iron bath and zinciferous material such as ZnO is then treated in the bath at a temp. (suitably about 1500°) at which the vapor pressure of the bath is low and the vapor pressure of the metal to be obtained is high so that reduction and volatilization of the latter is effected.

**Zinc oxide.** CHARLES A. H. DE SAULLES (to American Smelting & Refining Co.). U. S. 1,712,553, May 14. Zn ore is continuously reduced on a slag bath in a furnace having a slightly oxidizing atm. free from impurities, volatilized Zn products are removed to a sep. chamber of lower temp. than the furnace and contg. an excess of oxidizing agent such as air. ZnO is recovered. An arrangement of app. is described. Cf. C. A. 22, 306.

**Tilting and rotating furnace suitable for smelting.** ARTHUR JONES (to U. S. Smelting Furnace Co.). U. S. 1,712,769, May 14. Various structural details are given of a furnace having a burner mounted to be moved into and out of alignment with the furnace.

**Tiltable container for pouring molten metals.** LEE E. ALLEN (to Pennsylvania Engineering Co.). U. S. 1,712,287, May 7. Structural features.

**Apparatus with a tiltable rotating container for dipping articles in a galvanizing or tinning bath.** PATRICK J. KELLEY (to Ohio Brass Co.). U. S. 1,713,232, May 14. U. S. 1,713,233 relates to the use of a similar app. in which the articles to be coated are preliminarily tumbled with a dry flux and then dipped to coat them and freed from surplus coating, all in a continually rotating receptacle.

**Apparatus for casting non-ferrous metal slugs for making articles by extrusion.** WHEELING STAMPING CO. Brit. 299,489, June 28, 1927. Structural features.

**Ingot mold.** VEREINIGTE ALUMINIUM-WERKE A.-G. Ger. 475,077, Sept. 30, 1927.

**Ingot.** EMIL GATHMANN. U. S. 1,712,608, May 14. Ingots are formed of slab-like contour having a depth less than the width or length and with one at least of the larger areas concaved to a depth of one-eighth to one-fourth the thickness of the ingot.

**Hollow metal bars.** A. P. PEHRSON and F. LLOYD. Brit. 299,237, Jan. 20, 1928. A destructible core for use in rolling, drawing or forging of hollow bars from hollow billets comprises a helical sheath which may be formed of a strip of Cu or Cu alloy enclosing a center of pliable material such as sand or a rod of metal such as iron, mild steel, Cu or Cu alloy which will not melt during the working operation nor break during subsequent withdrawal. Cf. C. A. 23, 1104.

**Use of carbonaceous shale for improving ferrous metals.** ERNEST S. FISHER (to Utah Metals Flux Co.). U. S. 1,712,879, May 14. Metals such as cast iron or scrap are brought into contact in the molten state with a material such as the carbonaceous shale found in the northern central portion of Emery County, Utah, south of Price River and Desert Lake, in order to improve the strength and workability of the metal.

**Furnace for heating metal sheets and packs.** ARTHUR R. MCARTHUR and EDWIN E. MOORE (to American Sheet and Tin Plate Co.). U. S. 1,712,576, May 14. Structural features.

**Furnace for heat-treating metal articles.** THOMAS J. LAURENCE (to Chrysler Corp.). U. S. 1,712,831, May 14. Structural features.

**Furnace for heat treatment of long rods, tubes, etc.** HIRSCH KUPFER-UND MES-SINGWERKE A.-G. Brit. 299,453, Oct. 27, 1927. Structural features.

**Salt-bath furnace for hardening steel.** AXEL G. E. HULTGREN. U. S. 1,713,472, May 14. A method of operation is specified in which a fused salt bath is maintained in non-decarburizing condition by introduction of an acid, non-volatile oxide (preferably silica) in contact with the salt.

**Converter with lateral blowing for the production of steel.** JACQUES MORAT. Fr. 648,953, Feb. 14, 1928.

**Charging blast furnaces with furnace dust, etc.** PAUL HESKAMP (to Vereinigte Stahlwerke A.-G.). U. S. 1,713,435-6, May 14. Non-oxidizing gases are used for blowing the furnace dust or other materials into the furnace shaft above the smelting zone. Various structural details are described.

**Hot-blast installation for blast furnaces.** FREDERICK H. WILLCOX (to Freyn Engineering Co.). U. S. 1,713,313, May 14. Structural features.

**Burners and reversing valves for regenerative smelting furnaces.** WILHELM CORSALLI. Ger. 475,167, June 6, 1919.

**Crucible for melting lead, tin, zinc, etc.** WILHELM BUNDS. Ger. 475,076, Sept. 21, 1928. The crucible is made in part of metal and in part of refractory material, the parts being united so as to allow for relative expansion or contraction.

**Recovery of values from metallurgical flue gases.** JOHN D. McLACHLAN. *Fr.* 651,667, Mar. 24, 1928. Materials in smoke obtained in the extn. of Pb and other metals from ores, etc., are oxidized to produce a product similar to sublimed white lead. The materials may be heated in the smoke flue or after recovery, by heating directly or indirectly. If necessary air may be added to ensure complete oxidation, and gas or materials contg. S may be added to increase the sulfate content.

**Iron.** HERMANN VAN ROYEN. *Fr.* 651,612, Dec. 10, 1927. Pure Fe is obtained by bubbling through the bath of refined metal, non-carbonating reducing gas, the vol. of which is not increased by oxidation. Mixts. of CO, CO<sub>2</sub> and N in suitable proportions or of SO<sub>2</sub> and N may be used. The Fe obtained may be carbonated by passing a gas through having a carbonating action consisting of satd. hydrocarbons.

**Cast iron.** THE INTERNATIONAL NICKEL CO., INC., and PAUL D. MERICA, JAMES S. VANICK and THOMAS H. WICKENDEN. *Fr.* 651,242, Feb. 22, 1928. A gray cast iron which does not increase in vol. when heated and cooled repeatedly is obtained by replacing almost all the usual Si content by Ni. Examples given contain C 2.96, Si 0.7, Ni 3.47% and C 3.98, Si 0.19, Ni 3.84%.

**Gray cast iron.** THE INTERNATIONAL NICKEL CO. *Fr.* 650,815, Mar. 13, 1928. A gray cast iron of high tensile strength is obtained by adding to the white or mottled cast iron, after it has been tapped from the furnace, Al, Si, Ni and Mn either singly or together, which induce the formation of graphite. Examples are given.

**Cleaning iron and steel.** LA FILOCHIMICA. *Fr.* 650,705, Mar. 10, 1928. In the siderurgical industry baths contg. heavy tar oil, H<sub>2</sub>SO<sub>4</sub> (66° B<sub>e</sub>.) and oleum are used for cleaning Fe and steel to prepare them for successive treatments.

**Rustless steel.** SOC. ANON. DES ACIÉRIES ET FORGES DE FIRMINY. *Fr.* 651,459, Sept. 7, 1927. A rustless steel contains Mn 0.300–0.700, Si 0.400–1, Cr 5–6, Al 6–9, Ti 0.500–1 and C 0.050–0.600%.

**Alloys.** MEIER & WEICHELT EISEN UND STAHLWERKE. *Fr.* 650,845, Mar. 14, 1928. Fe alloys which are resistant to fire contain Cr 17–18, Ni 18–19, Si about 2, Mn about 1 and C about 0.6%.

**Alloys.** METALLBANK UND METALLURGISCHE GESELLSCHAFT A.-G. *Fr.* 650,419, Mar. 5, 1928. Cu-Si alloys suitable for the needs of the foundry contain Si 1–4, Fe 4–6, and Ni 1–4%. Zn, Sn, Mn and Al may also be present. Examples contain Si 2.5, Fe 5, Ni 5, Zn 10 and Sn 0.5 with or without 0.1% of Al and with or without 0.05% of Mn.

**Alloys for making springs and parts of plants subjected to friction, especially electrical conductors.** SIEMENS & HALSKE A.-G. (Georg Masing and Otto Dahl, inventors). *Ger.* 475,009 and 475,083, May 21, 1927. Alloys contg. Be and a predominating amt. of Ni, Co, or Fe are used. The alloys may be improved by thermal treatment. *Cf.* *Ger.* 469,218, and 469,219 (*C. A.* 23, 1103).

**White metal alloys.** A. L. Pocock. *Brit.* 299,493, July 25, 1927. Zn 85% or more is alloyed with Cu, Al and Ag, suitably in the relative proportions, resp., of 0.5–20.1 3:1 or less. Small addns. of Mg or other metals also may be made.

**Aluminum alloy.** ROLLS-ROYCE, LTD. *Fr.* 650,213, Feb. 29, 1928. An improved Al alloy contains Cr 0.05–4, Ni 0.2–1.5, Mg 0.1–1, Sb up to 0.5, Ti up to 0.5, Si 0.2–1.5, Fe 0.7–1.5 and Cu 2–5%. The amt. of Sb and Ti given is that added before or during fusion, the amt. finally remaining in the alloy being immaterial.

**Aluminum alloys.** COMPAGNIE DE PRODUITS CHIM. ET ÉLECTROMÉTALLURGIQUES ALAIS, FROGES ET CAMARGUE. *Fr.* 650,982, Mar. 17, 1928. Ti is introduced into Al alloys in the presence of, or in the form of, fluorides. The Ti may be alloyed with Al, Cu or Mn and added to the main mass of Al in the presence of fluorides, or the Ti may be introduced in the electrolytic manuf. of Al, which is carried out in the presence of fluorides (cryolite), or a double fluoride of Ti and an alkali metal may be mixed with powd. Al and added to the molten mass. The content of Ti may be 0.05–0.8, but preferably 0.5%. *Cf.* *C. A.* 23, 1103.

**Magnesium alloys.** JAHN A. GANN (to Dow Chemical Co.). U. S. 1,712,988, May 14. Alloys such as those of Mg contg. also about 8% Al and which may also contain other metals are heated in the form of castings to a temp. of about 430–5° for about 1 hr., in order to improve their strength, etc. U. S. 1,712,989 specifies subjecting alloys of Mg contg. also a minor proportion of a metal such as Al or Cu, or both, normally forming both a eutectic and a solid soln. with the Mg, to a heat treatment at a high temp. (suitably about 430°) below the m. p. of the eutectic, to effect complete soln. of the eutectic. U. S. 1,712,990 specifies successive heatings at higher temps. similarly successively to dissolve eutectics of 2 different metals present with the Mg, such as eutectics of 2 different metals present with the Mg, such as eutectics of Mg with Zn and Al, soln.

of which may be effected by heating at 335° and 430°, resp. Other metals such as Cu may also be present. Cf. *C. A.* 23, 88.

**Ferrous alloys containing chromium and tantalum.** PERCY A. E. ARMSTRONG. U. S. 1,711,484, May 7. A rust-, heat- and acid-resisting alloy suitable for cutlery, valves, etc., comprises Fe together with Cr 7-25, Ta about 0.2-3.0% and C about 1.25% or less. Mn and Si also may be added in small proportions.

**Iron alloy.** W. S. SMITH, H. J. GARNETT and J. A. HOLDEN. Brit. 299,502, July 27, 1927. Fe alloys free from C are formed contg. Cu and Si about 3-6% each and a small quantity of a deoxidizer such as Mn also may be added.

**Steel alloy.** EDUARD HOUDREMONT (to Fried. Krupp A.-G.). U. S. 1,711,733, May 7. A steel alloy which has high strength at high temps. comprises Cr 8-18, Mn 2-12, W 3-12% and 1% or less of C.

**Forgeable steel alloy.** JOHN L. COX. U. S. 1,711,519, May 7. An alloy is specified contg. C 0.35-1.5, Cr 4-20, W 6-18 and Al 1-6%, the remainder being mainly Fe. The proportion of W is not less than 1/4 that of the Cr and the proportion of Al is not less than one-sixth that of the W. Alloys of this compn. are suitable for valves operating at high temps.

**Alloy steel resistant to acids.** RALPH P. DEVRIES and HENRY A. DEFRIES (to Ludlum Steel Co.). U. S. 1,712,030, May 7. An alloy steel resistant to H<sub>2</sub>SO<sub>4</sub> and to mixed acids, and suitable for making tanks, valves, etc., exposed to acids contains Ni 14-30, Cr 6-20, Si 1-3, Ta 1-3, C 1% or less, the remainder being Fe.

**Circulatory apparatus for pickling metals.** HEINRICH OSWALD. Ger. 475,422, Jan. 16, 1927.

**Magnetic system for testing the hardness of ball-bearing rings, etc.** L. RENAULT. Brit. 299,388, Oct. 25, 1927.

**Heat treatment and quenching of metal rods and similar articles.** WALTER W. LÖCK (to Scullin Steel Co.). U. S. 1,713,136 7, May 14. An app. and mech. features are described.

**Apparatus for tempering metal-bar stock by electrical heating and quenching.** JOSEPH J. MASCUCH. U. S. 1,712,833, May 14. Structural features.

**Heat treatment of aluminum castings.** RANDOLPH J. ROBERT (to Bohn Aluminum & Brass Corp.). U. S. 1,713,093, May 14. Al alloys such as cast piston blanks contg. Al together with Cu 10, Fe 1, and Mg 0.5% are heated to a temp. as high as possible without distortion, quenched, and then reheated to about 220-250°, in order to refine the grain of the metal.

**Heat treatment of rolled steel.** NARAINA D. CHOPRA and FREDERICK J. BULLEN. U. S. 1,712,251 to 1,712,253, May 7. See Brit. patents 271,606, 271,529 and 271,530 (*C. A.* 22, 1568).

**Prevention of the corrosion of aluminum.** SOC. ANON. DES ÉTABLISSEMENTS LUCIEN AIRE. Fr. 650,587, Mar. 8, 1928. Corrosion of Al in contact with other metals forming herewith a galvanic couple is prevented by interposing a layer of Zn obtained in any suitable manner.

**Protective coating on iron.** EMIL LAY. U. S. 1,711,603, May 7. A diffused protective layer is formed on iron articles by heating with a pulverulent compn. contg. 8-30% of free metallic Al, and which also contains inert substances such as clay or alumina.

**Coating base metal jewelry, etc., with precious metals.** ERNST G. BEK and EUGEN THOMA (Thoma to Bek). U. S. 1,712,244, May 7. Articles of metal such as rings or buttons are coated with a film of a precious metal such as Au having a wt. less than 2.5% that of the article and the article and coating are heated to a temp. somewhat below the m. p. of either of the metals to effect interalloying and to produce a coating of desired color.

**Silvering metals.** LUCIEN J. V. GRANIER. Fr. 651,300, Jan. 25, 1928. See Brit. 296,695 (*C. A.* 23, 2415).

**Metal wire.** JAMES F. HOWE (to Am. Steel and Wire Co. of N. J.). U. S. 1,712,348, May 7. Wire is simultaneously drawn and coated by drawing stock such as ferrous metal through a body of dry metallic powder such as Zn, brass, Cu or Sn immediately prior to entry of the stock into the reducing die so that some of the powder will be drawn into the die with the stock and forced to adhere to the drawn wire.

**Arc-welding electrodes.** QUASI-ARC CO., LTD., and A. P. STROHMENGER. Brit. 299,575, Sept. 15, 1927. The core of a metal arc-welding electrode is covered with a matted fibrous silicate such as blue asbestos, amosite, or a mixt. of these. Loading materials for use in forming a flux or for varying the properties of the weld, such as Fe silicate, ferro-Si, ferro-Mn, V or Ti, may be added to the asbestos during the formation of the electrodes. Various mech. details of manuf. are described.

**Welding electrodes or rods.** B. TURNER and FERRO-ARC WELDING CO., LTD. Brit. 299,604, Oct. 19, 1927. A case of iron or steel is wound with a Ni wire to deposit an alloy of Fe and Ni in the weld and Cr and a small quantity of a deoxidizing agent such as Al also may be used. A filling mixt. may be used comprising powdered Cr 200, Al 2.5, fluorspar 35, limestone 15, and Na silicate 6 parts, with a coating mixt. of fluorspar 70, limestone 30,  $\text{Na}_2\text{CO}_3$  5 and Na silicate 6 parts. Cf. C. A. 23, 2927.

**Folded metal strip (enclosing a core and flux) for use in either electric arc or gas welding.** J. M. WARD (to British Thomson-Houston Co., Ltd.). Brit. 299,476, Oct. 27, 1927. Structural features.

**Solder for aluminum and its alloys.** LAURENCE R. PRESTON. U. S. 1,711,807, May 7. See Brit. 265,733 (C. A. 22, 379).

## 10—ORGANIC CHEMISTRY

CHAS. A. ROUILLER AND CLARENCE J. WEST

**Action of chlorosulfonic acid on substituted amides of cyanoacetic acid.** K. G. NAIK AND M. B. AMIN. *J. Indian Chem. Soc.* 5, 579–83 (1928).—The interaction of a no. of substituted amides (I) of  $\text{NCCH}_2\text{CO}_2\text{H}$  with  $\text{ClSO}_3\text{H}$  (II) was studied. The following compds. were prepd. by treating I with an excess of II in dry  $\text{CHCl}_3$ : *disulfo-cyanoacetanilide*,  $(\text{HO}_3\text{S})_2\text{C}(\text{CN})\text{CONHPh}$ , leaflets; corresponding *p-toluide*, leaflets; *o-toluide*; *m-toluide*, colorless shining scales; *α-naphthylamide*; *β-naphthylamide*, yellow needles; *benzylamide*, colorless plates; *xylide* (1,4,5) colorless shining scales. These compds. are very sol. in  $\text{H}_2\text{O}$ , and almost insol. in alc.,  $\text{CHCl}_3$ ,  $\text{CS}_2$ ,  $\text{CCl}_4$ , acetone, benzene, toluene,  $\text{Et}_2\text{O}$  and petroleum ether. They char when heated to 255–80°. The reactivity of the methylene H with II, that is absent with  $\text{NCCH}_2\text{CONH}_2$ , increases as Ph,  $\text{MeC}_6\text{H}_4$ ,  $\text{C}_{10}\text{H}_7$  are substituted in the amide group, showing that the rapidity with which the reaction proceeds depends on the electronegative character of the group. F. C. H.

**Organic chemistry and vital force.** P. E. VERKADE. Handelshoogschool, Rotterdam *Chem. Weekblad* 26, 238–45 (1929).—A lecture. G. CALINGAERT

**Pyroabietic acids from French rosin.** E. PONROBERT AND E. GRETH. *Chem. Umschau Fette, Oele, Wachse u. Harze* 36, 93–7 (1929).—A French rosin 2A had the following consts.: acid no. 168,  $[\alpha]_D^{20} = +12.7$ . After heating for 168 hrs. to 250° the consts. had changed to: acid no. 122,  $[\alpha]_D^{20} = +41.4$ . This product was then distd. in a high vacuum, yielding 200 g. rosin oil at 145–200° and 500 g. pyroabietic acid at 200–225° (both temp. of vapor), leaving 300 g. non-volatile residue at 245° (temp. of liquid). The pyroabietic acid, crystd. several times from acetone, m. 189° and  $[\alpha]_D^{20} = 8.4$ ; further crystn. from alc. increased the m. p. to 194° and  $[\alpha]_D^{20} = 15.2$ , acid no. 184.3 and mol. wt. 297; analysis showed the formula  $\text{C}_{20}\text{H}_{30}\text{O}_2$ , *l*-pyroabietic acid. The mother liquor yielded a *d*-pyroabietic acid,  $\text{C}_{20}\text{H}_{30}\text{O}_2$ , m. 156–8°,  $[\alpha]_D^{20} = +37.5$ , acid no. 184.4, mol. wt. 298. M. p. tests by mixing the isolated acids with equal parts of *l*- and *d*-abietic acid, m. 178° and 158°, resp., gave little depression of the m. p., indicating a very mild structural difference. By using Biot's law (*Bull. Inst. Pin* 1928, 127) to calc. the compn. of the crude pyroabietic acid, the following results were obtained: 90% *d*- and 10% *l*-pyroabietic acid. P. ESCHER

**α- and β-Diphenylindenes.** I. A. GARCÍA BANÚS AND F. CALVET. *Anales soc. españ. fis. quim.* 27, 49–59 (1929).—Previous articles (C. A. 7, 1019; 16, 3479; 18, 2144; 23, 2178) discuss the exact detn. of the constitution of diphenylisochroman. Condensation of *o*- $\text{OHCC}_6\text{H}_4\text{CH}_2\text{CHO}$  with  $\text{PhMgI}$  should give diphenylisochroman hydrate,  $\text{PhCH}(\text{OH})\text{C}_6\text{H}_4\text{CH}_2\text{CH}(\text{OH})\text{Ph}$ , which is dehydrated by distn. *in vacuo* in the presence of traces of Mg salts to a mixt. of α- and β-diphenylisochroman. *o*- $\text{OHCC}_6\text{H}_4\text{CH}_2\text{CHO}$  was not found in the literature, and attempts to obtain it by ozonizing indene were unsatisfactory. Ozonization breaks the nucleus, giving a compd. *o*- $\text{OHCC}_6\text{H}_4\text{CHPhBz}$  which by further oxidation forms a deriv. of  $\text{CH}_2\text{Ph}_2$  but never *o*- $\text{BzC}_6\text{H}_4\text{COBz}$ . α-Diphenylindene was obtained by the Orzechoff method (C. A. 8, 1115) by dehydration of benzylhydrobenzoin by heating with  $\text{AcCl}$  and isomerizing the β-diphenylindene so obtained by alc.  $\text{Na}_2\text{CO}_3$ . A large excess of  $\text{AcCl}$  is used. If the excess is recovered and re-used there is formed, in place of β-diphenylindene, a compd. resembling benzylhydrobenzoin acetate. This difference can only be due to volatile impurities in the  $\text{AcCl}$ . Very well fractionated  $\text{AcCl}$  does not dehydrate benzylhydrobenzoin and gives only the monoacetate. Addn. of a small amt. of  $\text{SO}_2\text{Cl}_2$

to the  $\text{AcCl}$  gives the dehydrating action. Benzylhydrobenzoin, m.  $154-5^\circ$ , is prepd. in anhyd.  $\text{Et}_2\text{O}$  from benzoin,  $\text{PhCH}_2\text{Cl}$  and  $\text{Mg}$  filings, and is dehydrated with  $\text{AcCl}$  to form  $\beta$ -diphenylindene, m.  $173-5^\circ$ , which rearranges on treatment with alc.  $\text{K}_2\text{CO}_3$  to form  $\alpha$ -diphenylindene, m.  $110^\circ$ . The oxime was obtained by treating diphenylindene in alc. with  $\text{Na}$  in alc., adding recently distd. iso-AmONO. The oxime was reduced with  $\text{Zn}$  powder by heating in  $\text{AcOH}$ , the soln. was cooled, poured into  $\text{H}_2\text{O}$ , an excess of  $\text{NH}_4\text{OH}$  added and extd. with  $\text{Et}_2\text{O}$ , the  $\text{Et}_2\text{O}$  soln. filtered and pptd. by concd.  $\text{HCl}$ , giving aminodiphenylindene- $\text{HCl}$ , which is recrystd. from alc. contg. a few drops of concd.  $\text{HCl}$ , giving aminodiphenylindene. Finely ground  $\alpha$ -diphenylindene dissolved in hot  $\text{HOAc}$  and a 2.8%  $\text{O}_2$  in  $\text{O}_2$  passed through for 90 mins., allowed to stand 1 hr., deposits white needles of (*o*-benzoylphenyl)benzoylcarbinol, m.  $121-3^\circ$ . The mother liquor gives more crystals by partial evapn. *in vacuo*. The carbinol, dissolved in alc. and  $\text{PhNHNH}_2$  (twice theoretical) added with a few drops of  $\text{HOAc}$ , heated under reflux 0.5 hr., cooled, gives the monophenylhydrazone, m.  $143-5^\circ$  if recrystd. from  $\text{Et}_2\text{O}$ . The diketone, dissolved in alc. in a flask having a reflux condenser and a tube to pass in  $\text{H}$  to give a reducing atm. and avoid resinification,  $\text{NH}_2\text{OH}\cdot\text{HCl}$  added and a little  $\text{K}_2\text{CO}_3$  until alk. to phenolphthalein, heated 15 mins. on a water bath, cooled, poured into  $\text{H}_2\text{O}$ , acidified with  $\text{H}_2\text{SO}_4$ , extd. with  $\text{C}_6\text{H}_6$ , avoiding agitation and contact with air, the  $\text{C}_6\text{H}_6$  removed by a vacuum, gives *o*-(benzoylphenyl)-benzoylcarbinol dioxime, m.  $178-80^\circ$ . One g. of carbinol, dissolved in boiling acetone and oxidized by boiling with the calcd. quantity of  $\text{KMnO}_4$ , the pptd.  $\text{Mn}$  compd. filtered off and the liquid concd., gives yellow octahedrons, m.  $92^\circ$ , identical with *o*-Bz- $\text{C}_6\text{H}_4\text{COBz}$  obtained by García Banús by oxidation of  $\alpha$ -diphenylindene by  $\text{KMnO}_4$  in acetone.

E. M. SYMMES

The decomposition of methane. CYRIL W. H. JONES. Univ. London. *J. Chem. Soc.* 1929, 419-22.—The decompn. of  $\text{CH}_4$  was investigated at various temps and pressures and under the influence of the elec. spark. The gas was passed through a heated quartz tube of 1-mm. bore at temps.  $700-1080^\circ$ , pressures 10-70 cm. Hg, and various rates of flow.  $\text{CH}_4$  decompd. partly into  $\text{C}$ ,  $\text{H}$  and smaller quantities of olefins and acetylenes. When sparked,  $\text{CH}_4$  gave the same products, but the quantities of olefins and acetylenes were larger and small quantities of solid and liquid hydrocarbons were also formed.

M. W. SEYMOUR

The action of optically excited mercury atoms on hydrocarbon molecules. WALTER FRANKENBURGER AND ROBERT ZELL. *Z. physik. Chem.*, Abt. B, 2, 395-8 (1929).—The primary reaction between excited  $\text{Hg}$  atoms and pentane vapor mols. consists of a loosening of the  $\text{C-H}$  or  $\text{C-C}$  linkage independent of the air,  $\text{N}$  or  $\text{CO}$  solvent gases. The liberated  $\text{H}$  atoms and hydrocarbon radicals undergo secondary reactions (1) with each other in  $\text{N}$  and at times in  $\text{CO}$  to give  $\text{H}$  and higher and lower hydrocarbons and (2) with air to yield  $\text{H}_2\text{O}_2$ , and  $\text{O}$ -contg. compds. with  $\text{Ac}$  or  $\text{MeC}(\text{OH})$  groups.  $\text{H}$  atoms combine with  $\text{CO}$  to produce  $\text{HCHO}$  and  $(\text{CHO})_2$ . A combination of hydrocarbon radicals with  $\text{CO}$  is uncertain.

H. W. WALKER

The reaction of atomic hydrogen with hydrocarbons. HUGH S. TAYLOR AND DOUGLAS G. HILL. Princeton Univ. *Z. physik. Chem.*, Abt. B, 2, 449-50 (1929).—In the presence of a large excess of  $\text{H}_2$ ,  $\text{C}_2\text{H}_4$  is changed almost completely to  $\text{C}_2\text{H}_6$  by excited  $\text{Hg}$  atoms. However, with relatively higher concns. of  $\text{C}_2\text{H}_4$ , more complex satd. hydrocarbons are formed. With equal proportions of  $\text{C}_2\text{H}_4$  and  $\text{H}_2$ , the satd. hydrocarbon formed has a mean mol. wt. corresponding to  $\text{C}_4$ . Besides the hydrogenation, other reactions take place with the liberation of  $\text{H}_2$  and formation of liquid condensation products of the type  $(\text{CH}_2)_n$ .  $\text{CH}_4$  has also been identified in the product. With a large excess of  $\text{C}_2\text{H}_4$ ,  $\text{C}_2\text{H}_2$  is also formed.

H. F. JOHNSTONE

The estimation of unsaturation with potassium bromide-potassium bromate mixture. FRANK CORTESE. Mass. Inst. of Technology. *Rec. trav. chim.* 48, 564-7 (1929).—Two methods are presented for the detn. of unsatn. with  $\text{KBr-KBrO}_3$  mixt. (A). The theoretical quantity and 1 cc. more of the  $\text{KBr-KBrO}_3$  mixt., prepared according to Francis (*C. A.* 21, 645) are delivered into a 150-cc. glass stoppered Erlenmeyer flask, cooled in ice water. One cc. of the sample of known temp. and d. is added and then 5 cc. 10%  $\text{H}_2\text{SO}_4$ , the flask being shaken until the color is persistent during a few minutes. Ten cc. more of 10%  $\text{H}_2\text{SO}_4$  is added and the flask is shaken 1 more minute. Then 1 cc. of satd.  $\text{KI}$  soln. is added, the liberated  $\text{I}$  being titrated at once with  $\text{Na}_2\text{S}_2\text{O}_3$  (B). This procedure is used when only small quantities of material are available. One cc. of sample is dild. with 10 cc. of pure  $\text{CCl}_4$  and an aliquot portion of 1 cc. is taken for each analysis, with 0.1 *N*  $\text{KBr-KBrO}_3$  and 0.04 *N*  $\text{Na}_2\text{S}_2\text{O}_3$  and an excess of only 0.1-0.2 cc.  $\text{KBr-KBrO}_3$  mixt. The following results were obtained: 2-pentene (A) 0.99, (B) 0.99 (theory: 1.00); trimethylethylene (A) 1.00, (B) 1.02

(1.00); 1-decene (B) 0.83 (1.00); 1-cetene (B) 0.94 (1.00); 1,5-hexadiene (A) 1.94, (B) 1.98 (2.00); 2,4-hexadiene (A) and (B) both 1.94 (2.00); 2,4-pentadiene (A) 1.90 (2.00); dipentene (A) 1.84 (2.00); 2-chloro-5-hexene (B) 0.93 (1.00); allyl bromide (B) 0.97 (1.00); allyl alc. (B) 0.96 (1.00); indene (B) 0.83 (1.00); furan (B) 1.02 (2.00); phenylbutadiene polymer (B) 1.00 (2.00). From these results it follows that the methods are suitable for aliphatic olefins and diolefins, whether conjugated or not, but that it is unreliable for certain ring structures and for substances of unknown constitution. Finally, details on the prepn. of the compds. tested are given.

C. F. VAN DUIN

**The sodium acid salts of palmitic acid.** PER EKWALL AND WILHELM MYLIUS. *Physik. chem. Inst. Akad. Åbo, Finland. Ber.* 62B, 1080-4(1929); cf. C. A. 22, 3864.—Previous studies of the phys. properties of aq. solns. of Na palmitate and palmitic acid have indicated the existence of salts of the compns.:  $2\text{NaPl}:\text{1HPl}$ ;  $\text{1NaPl}:\text{1HPl}$ ; and  $\text{1NaPl}:\text{2HPl}$ . These have been isolated from alc. soln. and their existence was confirmed by analysis, mol. wt. measurements and their const. m. ps.  $2\text{NaPl}:\text{1HPl}$ , m. 115-7°.  $\text{1NaPl}:\text{1HPl}$ , m. 97-8°.  $\text{1NaPl}:\text{2HPl}$ , m. 81-2°.

A. J. K.

**Preparative notes on the preparation of several aliphatic unsaturated acids and esters.** ERNST PHILIPPI. Univ. Innsbruck. *Monatsh.* 51, 277-9(1929).—P. quotes the best methods reported in the literature for elaidic acid and its Et ester, Et  $\beta$ , $\beta$ -dimethylacrylate, allyl alc., allylacetoacetic Et ester, allylacetic Et ester, vinylacetic acid, sorbic acid and hydrosorbic acid.

C. J. WEST

**Action of ammonia and amines upon esters of unsaturated acids.** ERNST PHILIPPI AND EBERHARD GALTER. Univ. Innsbruck. *Monatsh.* 51, 253-66(1929).—A review of previous work, with references, is given. Et oleate and elaidate do not react with liquid  $\text{NH}_3$ ; Et crotonate gives 55% of  $\text{MeCH}(\text{NH}_2)\text{CH}_2\text{CO}_2\text{Et}$ , m. 64-5°; with  $\text{MeNH}_2$  there results a small quantity of  $\text{MeCH}(\text{NHMe})\text{CH}_2\text{CO}_2\text{Et}$ ,  $b_{15}$  75-7°, but the main product,  $\beta$ -methylaminobutyric methylamide,  $b_{15}$  146°; with piperidine, heated 2.5 hrs. at 120°, the only product is Et  $\beta$ -piperidinobutyrate,  $b_{15}$  125° (60% yield). Et  $\alpha$ -ethylacrylate does not react with liquid  $\text{NH}_3$  or with  $\text{MeNH}_2$ . Et  $\beta$ -dimethylacrylate and  $\text{NH}_3$  give about 60% of the addn. product but no amide;  $\text{MeNH}_2$  gives some Et  $\beta$ -methylaminosuccinate,  $b_{14}$  74.5-5.5°, but the main product was the methylamide,  $b_{15}$  138-40°; piperidine does not react. Et allylacetate scarcely reacts with  $\text{NH}_3$ . Et acrylate and piperidine give 87% of Et  $\beta$ -piperidinopropionate,  $b_{12-13}$  104-6°. Me hydrosorbate and liquid  $\text{NH}_3$  give only the amide; Me sorbate and Et phenylisocrotonate behave similarly.

C. J. WEST

**Stability of amyl trichloro acetate in various solvents.** L. M. ANDREASOV. *Ukrainskii Khim. Zhur.* 3, Sci. pt., 467-70(1928); cf. C. A. 23, 322.—A. studied the decompn. of  $\text{Cl}_3\text{CCO}_2\text{Am}$  (I) mixed with  $\text{Cl}_3\text{CCO}_2\text{H}$  in such solvents as  $\text{CHCl}_3$ ,  $\text{CCl}_4$ ,  $\text{C}_6\text{H}_6$ ,  $\text{Me}_2\text{CO}$ ,  $\text{PhNO}_2$ ,  $\text{Et}_2\text{O}$ ,  $\text{BzOEt}$  and  $\text{CS}_2$  at 25° and 50°, finding that it proceeds at the lowest rate in  $\text{C}_6\text{H}_6$  at 25° and in  $\text{PhNO}_2$  at 50° and at the highest rate in  $\text{CS}_2$  at 25° and 50°. The rate of formation of I from  $\text{Cl}_3\text{CCO}_2\text{H}$  and amylene is much faster than the rate of decompn. of I into its components in the same solvents.

CHAS. BLANC

**Velocity of esterification of alcohols in formic acid.** ANTON KAILAN AND GERTRUD BRUNNER. Univ. Wien. *Monatsh.* 51, 334-68(1929).—The velocity of esterification of  $\text{Me}_3\text{COH}$ ,  $\text{Me}_2\text{CHOH}$ ,  $\text{HOCH}_2\text{CH}_2\text{O}_2\text{CH}$  and  $\text{HOCH}(\text{CH}_2\text{O}_2\text{CH})_2$  in  $\text{HCO}_2\text{H}$  contg. 0.1 and 1.2 mols.  $\text{H}_2\text{O}$  at the beginning of the expt. (and with  $\text{HCl}$  as catalyzer in the case of  $\text{Me}_3\text{COH}$ ) was detd. at 25° (also 15° for  $\text{Me}_3\text{COH}$ ) by measuring the f. p. lowering and the coeffs.  $k_1$  +  $k_2$ , calcd. from the equation for monomol. reactions, obtained, through interpolation formulas, as functions of the  $\text{H}_2\text{O}$  content of the  $\text{HCO}_2\text{H}$ . Increasing the  $\text{H}_2\text{O}$  content from 0.3 to 1.37 mol. per l. decreases the value of  $k_1$  +  $k_2$  for  $\text{Me}_3\text{COH}$  by 46%, for the sec. alcs. ( $\text{Me}_2\text{CHOH}$  and  $\text{HOCH}(\text{CH}_2\text{O}_2\text{CH})_2$ ) 15 and 21% and for  $\text{HOCH}_2\text{CH}_2\text{O}_2\text{CH}$  by 30%. Under the exptl. conditions  $\text{Me}_3\text{COH}$  and 1,3- $\text{CHOH}(\text{CH}_2\text{O}_2\text{CH})_2$  were esterified 70-80%,  $\text{HOCH}_2\text{CH}_2\text{O}_2\text{CH}$  80-90% and  $\text{Me}_2\text{CHOH}$  92-100%. The coeffs. of  $\text{Me}_3\text{COH}$  and  $\text{HOCH}_2\text{CH}_2\text{O}_2\text{CH}$  are about equal but only about half that of  $\text{Me}_2\text{CHOH}$ ; the coeff. of the latter is about 10 times that of  $\text{HOCH}(\text{CH}_2\text{O}_2\text{CH})_2$ . With  $N/120$   $\text{HCl}$ , the coeff. for  $\text{HOCH}(\text{CH}_2\text{O}_2\text{CH})_2$  is increased 4 times, that for the other alcs. is doubled. Increasing the temp. from 15° to 25° increases the value for  $\text{Me}_3\text{COH}$  3.2 times, but only 2.4 times when  $\text{HCl}$  is used as catalyzer.

C. J. WEST

**Imide and amide chlorides of non-aromatic acids.** III. JULIUS V. BRAUN AND ALBRECHT HEYMANS. Univ. Frankfurt a. M. *Ber.* 62B, 409-13(1929); cf. C. A. 21, 2875.—It was shown in the earlier papers that the instability of imide chlorides,  $\text{RCCl}:\text{NR}'$ , derived from non-aromatic acids, is conditioned chiefly by a H atom

in R, adjacent to the  $-CCl<$  group, migrating to the N with formation of a compd.  $>CCINHR'$ . If there is no such H atom the imide chlorides are as stable as or even more so than those derived from aromatic acids; thus, while  $PhCCl:NMe$  decomps. at high temps. into  $PhCN$  and  $MeCl$  the imide chloride of fencholic acid is quite stable. The change in stability in passing from the derivs. of aromatic acids to those of non-aromatic acids with the  $CO_2H$  group bound to a tertiary C atom is only a gradual one, however; thus, campholic *N*-methylimide chloride, when refluxed some time and then distd. under atm. pressure, gives campholic nitrile, and the ethyl- and isomylimide chlorides behave in the same way (these chlorides were prepd. with  $PCl_5$  from campholic ethylamide,  $b_{20}$   $160^\circ$ , m.  $88^\circ$ , and isoamylamide,  $b_1$  about  $150^\circ$ , m.  $42-3^\circ$ ). The question naturally suggested itself whether the amide chlorides derived from dialkylated amides would show the same analogy in behavior between the aromatic and non-aromatic compds. Amides of acids of the 3 types  $R_3CCO_2H$ ,  $RCH_2CO_2H$  and  $R_2CHCO_2H$  were studied. (1) *Trichloroacetic diethylamide*,  $b_{12}$   $108-12^\circ$ . Campholic diethylamide,  $b_{12}$   $140-5^\circ$ , m.  $29-30^\circ$ . Neither of these 2 amides reacted with  $PCl_5$  even on long heating on the  $H_2O$  bath. (2) *Chloroacetic diethylamide*,  $b_{10}$   $112-3^\circ$ . Butyric diethylamide,  $b_{12}$   $92^\circ$ . The former with  $PCl_5$  in  $CHCl_3$  evolves a little  $HCl$  and forms an oil which undergoes deep-seated decompn. on attempted distn. With the 2nd amide the decompn. is not so pronounced; about 80% of the product  $b_{10}$   $60-85^\circ$  and the distillate seps. into 2 layers: heavy oil (I) of penetrating odor, and a lighter oil (II),  $b_{13}$   $100-7^\circ$ . I is free of O, regenerates the amide with  $H_2O$  and, from its Cl content (37.54%), consists chiefly of the amide chloride; on standing it darkens and on distn. ( $60-90^\circ$  under 10 mm.) it again loses  $HCl$  and forms more II. The compn. of II (Cl 22.7, N 8.46%) shows that the amide chlorides  $RCH_2CCl_2NR'_2$  of aliphatic acids do not split off  $R'Cl$  like those of the aromatic acids, but  $HCl$  to form compds. of the type  $RCH:CCINR'_2$ . (3) *Methylethylacetic diethylamide*,  $b_{11}$   $84-6^\circ$ , gives with  $PCl_5$  70% of a turbid distillate,  $b_{12}$   $71-102^\circ$ , sepg. into 2 layers: one, the almost pure amide chloride (III), is immediately hydrolyzed to the original amide by  $H_2O$ , while the other,  $EtMeC:CCINEt_2$ ,  $b_{13}$   $76-85^\circ$ , is relatively stable toward  $H_2O$ , only about 0.5 of the Cl being hydrolyzed off by shaking 5 mins. with ice  $H_2O$ . III reacts very energetically with  $PhNH_2$  in  $CHCl_3$ , giving almost quantitatively the amidine,  $EtMeC:CHC:(NPh)NEt_2$ , faintly yellow refractive liquid (chloroplatinate, light yellow, decomp.  $124-7^\circ$ ). While aromatic and aliphatic-aromatic imide chlorides (and bromides), in the form resulting from the shifting of the H, can add Cl and Br, e. g.,  $RCH_2CCl:NR' \rightarrow RCH:CCINHR' + Br_2 \rightarrow RCHBrCCIBrNHR' \rightarrow RCHBrCCl:NR' (+ RCHBrCBr:NR') + HBr (+HCl)$ , they do not add I and  $\alpha$ -I acids can therefore not be prepd. in this way. If the acid radical contains a double bond, formation of the imide chloride, exhaustive chlorination of the  $\alpha$ -C atom and addn. of Cl at the double bond can all be effected in 1 operation with  $PCl_5$ ; thus, *undecylenic ethylamide*, m.  $35^\circ$ , heated 2.5 hrs. on the  $H_2O$  bath with 5.2 mols.  $PCl_5$ , gave 60% of 1,1,9,10-tetrachloroundecylic ethylamide,  $b_{0-2}$  about  $180^\circ$ . C. A. R.

**Manufacture of ethylene chlorohydrin.** M. B. ZAPADINSKII. *J. Chem. Ind. (Moscow)* 5, 1426-9(1928).—Preference is given to the *method of prep.*  $CH_2ClCH_2OH$  by passing  $C_2H_4$  and Cl into  $H_2O$ . Five hundred cc.  $H_2O$  is placed in an externally ice-cooled jar of 1.5-l. capacity, and Cl and  $C_2H_4$  are simultaneously passed through tubes reaching to the bottom of the vessel and terminating with narrow outlets. The temp. is maintained at  $\pm 2^\circ$ , the speed of the stirrer at 800 r. p. m. The pressure in the app. is kept up by 150-200 mm.  $H_2O$ . The quantities of the gases and their speed are carefully noted. It is not possible to maintain a uniform speed, as the inert gases formed dil. the  $C_2H_4$  and cause a slackening of absorption. The vol. of the liquid gradually increases. Z.'s method (C. A. 22, 3864) is used for chlorohydrin detn. at various stages of the process. Expts. made with the addn. of  $(CH_2Cl)_2$  (to increase the soly. of the Cl) or with  $EtOH$  (to increase the soly. of the  $C_2H_4$ ) resulted in considerable decreases of yield, as  $(CH_2Cl)_2$  acts by preventing the hydrolysis of Cl, whereas  $EtOH$  uses up much Cl for oxidation. Brooks' suggestion to operate in presence of gasoline is of doubtful use. To sep. chlorohydrin from the dil. solns. obtained, 3 operations are required, the 1st being the distn. The 1st 10-12% of the distillate contains 80-85% of the chlorohydrin, the next 10-15% contains the rest, only 2-3% remaining behind. The addn. of salts has but an insignificant effect on the distn., unless the operation is carried out *in vacuo*; the addn. of  $C_2H_4$  is needed to decrease the partial pressures. The 2nd distd. fraction is added to the crude product, whereas the 1st is subjected to the 2nd operation, viz., extn. It is advisable to ext. at first twice with  $(CH_2Cl)_2$  obtained as a by-product in this process and contg. chlorohydrin, then twice with pure  $(CH_2Cl)_2$ , taking each time a vol. of the solvent equal to 20% of the soln.

The 3rd operation consists in sepg. the chlorohydrin from  $(\text{CH}_2\text{Cl})_2$  by distn. through a dephlegmator, either at ordinary pressure or *in vacuo*. BERNARD NELSON

**Amino acetals and amino aldehydes with three carbon chains.** R. VOET. *Bull. soc. chim.* 45, 61-9(1929).—The difference in physiol. activity between natural and synthetic muscarines raised a question as to their chem. identity, accordingly the pharmacodynamic activity of secondary and tertiary 3-C amino aldehydes was studied. Synthesis was accomplished by substitution of  $\text{RHN}$  or  $\text{R}_2\text{N}$  for  $\text{Cl}$  in  $\gamma$ -chloropropionyl acetals followed by hydrolysis with cold concd.  $\text{HCl}$ . Contrary to expectation, the various compds. examd. were non-toxic and practically without physiol. action. The reactions were carried out by heating 2 mols. of amine with 1 mol. of chloro acetal to  $100^\circ$  for from a few hrs. to 3-4 days in sealed tubes. The oily amino acetals were washed out of the cryst. amine  $\text{HCl}$  salts with  $\text{Et}_2\text{O}$  and purified by distn. *in vacuo*. Methylaminopropionaldehyde dimethyl acetal (66% yield),  $b_{760}$   $164.5^\circ$ ,  $\text{HCl}$  salt, hygroscopic plates; tetramethyl acetal (by-product), yellowish oil,  $b_{20}$  about  $130^\circ$ ,  $d_{20}$   $0.9759$ ; ethylaminopropionaldehyde dimethyl acetal (70% yield),  $b_{760}$   $177.3^\circ$  (cor.),  $\text{HCl}$  salt, hygroscopic plates; tetramethyl acetal (by-product), faintly colored oil,  $b_{20}$  about  $133^\circ$ ,  $d_{20}$   $0.9608$ ; propylaminopropionaldehyde dimethyl acetal (60% yield),  $b_{760}$   $195.5^\circ$ ,  $d_{20}$   $0.9002$ ,  $\text{HCl}$  salt, white crystals; tetramethyl acetal (by-product), slightly colored oil,  $b_{20}$  about  $140^\circ$ ,  $d_{20}$   $0.9483$ ; diethylaminopropionaldehyde dimethyl acetal (95% yield after 100 hrs. heating), strongly basic,  $b_{760}$   $194.2^\circ$ ,  $d_{20}$   $0.8846$ ,  $\text{HCl}$  salt, fine, white, silky, hygroscopic needles; dipropylaminopropionaldehyde dimethyl acetal (82% yield after 85 hrs.), slightly oily, colorless liquid, almost insol. in  $\text{H}_2\text{O}$ ,  $b_{760}$   $223.4^\circ$ ,  $d_{20}$   $0.8715$ ,  $\text{HCl}$  salt, hygroscopic, sirupy oil crystg. with difficulty. All the amino aldehydes reported form  $\text{HCl}$  salts which refuse to crystallize, are hygroscopic, and dissolve in  $\text{H}_2\text{O}$ , abs.  $\text{EtOH}$  and glacial  $\text{AcOH}$  but not in ether. All are accompanied in the reaction by similar polymers which do not show the above solubilities and which must lack free  $-\text{CHO}$  groups since they do not reduce Fehling solu although the aldehydes themselves do. The ethylaminopropionaldehyde which has been elsewhere studied appears to form a trimol. polymer. The amino aldehydes and their polymers form identical semicarbazones, which proves their relationship. Semicarbazones: methylaminopropionaldehyde, m.  $300^\circ$ ; ethylaminopropionaldehyde, m.  $301.5^\circ$ ; propylaminopropionaldehyde, m.  $303^\circ$ ; diethylaminopropionaldehyde, m.  $309.5^\circ$ . Polymerized diethylaminopropionaldehyde chloraurate, decomps. about  $100^\circ$ . C. H. PEET

**Formylmethionine and formylbromomethionine acids.** H. J. BACKER. Univ. Groningen. *Rec. trav. chim.* 48, 571-6(1929).—Three methods exist for the prepn. of formylmethionine acid (a) addn. of  $\text{H}_2\text{S}_2\text{O}_7$  to  $\text{C}_2\text{H}_2$  (*Ann.* 303, 119(1898)); (b) sulfonation of  $\text{AcH}$  with  $\text{H}_2\text{S}_2\text{O}_7$  (*Bull. soc. chim.* [3], 27, 7(1902)); (c) the interaction of chloral and  $\text{K}_2\text{SO}_3$  (*Ann.* 161, 154(1872)). According to B.'s experience the latter method gives the best results: 45 g.  $\text{K}_2\text{S}_2\text{O}_8$  and 28 g.  $\text{K}_2\text{CO}_3$  are dissolved in 75-cc. water and the soln. is boiled to remove the  $\text{CO}_2$  formed; then it is cooled down to  $80^\circ$  and 15 g. chloral (16.5 g. of the hydrate) is added with continuous shaking, the temp. being kept at  $85^\circ$ . On cooling the  $\text{K}$  salt of the bisulfite compd. of formylmethionine acid,  $\text{KHSO}_3\text{OCH}(\text{CH}(\text{SO}_3\text{K})_2)\text{H}_2\text{O}$  (I), is obtained, which can be purified by recrystn. from water; yield 15 g. With hot dil. alkali I decomps. with the formation of methionine and formic acids, whereas the action of hot dil.  $\text{HCl}$  yields the  $\text{K}$  formylmethionate,  $\text{C}_4\text{H}_7\text{O}_7\text{S}_2\text{K}_2\text{H}_2\text{O}$ , in theoretical yield; 100 g. water dissolves at  $25^\circ$  1.02 g. The following salts were prepd. in the usual way: Ba,  $\text{C}_4\text{H}_7\text{O}_7\text{S}_2\text{Ba} \cdot 4\text{H}_2\text{O}$ ; Ag,  $\text{C}_4\text{H}_7\text{O}_7\text{S}_2\text{Ag} \cdot \text{H}_2\text{O}$ ; Tl,  $\text{C}_4\text{H}_7\text{O}_7\text{S}_2\text{Tl}_2 \cdot \text{H}_2\text{O}$ ; 100 g. of water dissolves at  $25^\circ$  0.3245 g. of the anhyd. Ba salt. On adding gradually to a boiling soln. of 30 g. of the  $\text{K}$  salt and 1 g.  $\text{KBr}$  the theoretical amount of  $\text{Br}$ , or on heating I with 4 atoms of  $\text{Br}$  in a sealed tube at  $100^\circ$  for 2 hrs.,  $\text{K}$  formylbromomethionate,  $\text{C}_4\text{H}_7\text{O}_7\text{BrS}_2\text{K}_2\text{H}_2\text{O}$ , is obtained on cooling with 80% yield; Ba salt,  $\text{C}_4\text{H}_7\text{O}_7\text{BrS}_2\text{Ba} \cdot 2\text{H}_2\text{O}$ . With hot dilute alkali formylbromomethionine acid is decompd. into bromomethionine and formic acids while with  $\text{KHSO}_3$  reduction takes place at room temp. with formation of I. C. F. VAN DUIN

**Carnitine.** WILHELM LINNEWIEH. Univ. Würzburg. *Z. physiol. Chem.* 182, 8-12(1929).—The "apocarnitine" which Engeland (*C. A.* 16, 1079) obtained by dehydration of carnitine with concd.  $\text{H}_2\text{SO}_4$  and thought to be  $\alpha$ -methylene- $\beta$ -butyrobetaine was undoubtedly the crotonobetaine prepd. synthetically by L. (*C. A.* 22, 3135) The identity is now established by prepn. of the so-called apocarnitine and comparison of its properties with those of crotonobetaine. Both decolorize  $\text{KMnO}_4$  and on hydrogenation yield  $\gamma$ -butyrobetaine. Krimberg (*C. A.* 2, 1292) probably had crotonobetaine and mistook it for  $\gamma$ -butyrobetaine when he heated carnitine with  $\text{HI}$  and  $\text{P}$ . This treatment removes  $\text{H}_2\text{O}$  from carnitine but does not hydrogenate the

resulting crotonobetaine. The  $\text{AuCl}_3$  salts of synthetic and natural crotonobetaine are apparently different in cryst. form, although mixts. give no depression in m. p. The difference may be due to some minute impurity or to isomerism. A. W. DOX

Further studies on the problem of the specificity of enzymic cleavage of polypeptides. Experiments with polypeptides containing *dl*-norleucine. EMIL ABDEKHALDEN AND HUGO MAYER. Univ. Halle. *Fermentforschung* 10, 464-73(1929).—New derivs. described include 3 dipeptides and their  $\text{PhNCO}$  derivs. and 3 tripeptides, all contg. *dl*-norleucine. *dl*-Norleucine in *N* NaOH was condensed with *dl*- $\text{BuCHBrCOCl}$  yielding 59.5% of *dl*- $\alpha$ -bromocaproyl-*dl*-norleucine, m. 104°. Amination by 25%  $\text{NH}_4\text{OH}$  converted this into 75.7% *dl*-norleucyl-*dl*-norleucine, m. 259° (*PhNCO* deriv. m. 198°). In the same manner *dl*-norleucine reacted with *dl*- $\text{Me}_2\text{CHCH}_2\text{CHBrCOCl}$  to form 65.5% *dl*- $\alpha$ -bromoisocaproyl-*dl*-norleucine, m. 136°, which on amination yielded 63% *dl*-leucyl-*dl*-norleucine, m. 256° (*PhNCO* deriv. m. 186°). *dl*-Leucine and *dl*- $\text{BuCHBrCOCl}$  yielded 74% *dl*- $\alpha$ -bromocaproyl-*dl*-leucine, m. 158°, from which the dipeptide *dl*-norleucyl-*dl*-leucine, m. 253°, was obtained in 84.5% yield by amination (*PhNCO* deriv. m. 202°). Glycylnorleucine and *dl*- $\text{BuCHBrCOCl}$  yielded 78.65% *dl*- $\alpha$ -bromocaproylglycyl-*dl*-norleucine, m. 118°, from which the tripeptide *dl*-norleucylglycyl-*dl*-norleucine, m. 250°, was obtained in 88% yield. Glycyl-*dl*-leucine and *dl*- $\text{BuCHBrCOCl}$  gave *dl*- $\alpha$ -bromocaproylglycyl-*dl*-leucine, m. 127°, which was converted into 63% *dl*-norleucylglycyl-*dl*-leucine, m. 245°. Norleucylnorleucine and leucylnorleucine were omitted from the hydrolysis tests because of their insol., and the previously described glycyl-*dl*-norleucine and *dl*-leucylglycyl-*dl*-norleucine included. All of these derivs., whether peptides or haloacyl derivs., but not the 3  $\text{PhNCO}$  derivs., were hydrolyzed by *N* NaOH at 37°. Erepsin hydrolyzed the peptides, but the acyl derivs. only in traces. Trypsin hydrolyzed all of these substances, with the exception of the 2 dipeptides tested, viz., the acylamino acids and acyldipeptides, the tripeptides and the  $\text{PhNCO}$  derivs. A. W. DOX

Some crystallized anhydrides of monosubstituted malonic acids. C. MANNICH AND A. BUTZ. Pharmazeut. Inst., Berlin. *Ber.* 62B, 456-60(1929).—The few anhydrides of malonic acids hitherto described are amorphous, apparently polymeric substances. When, however,  $\text{BzCH}_2\text{CHPhCH}(\text{CO}_2\text{H})_2$  is heated at 70° in  $\text{C}_6\text{H}_6$  with  $\text{SOCl}_2$  it yields a beautifully crystd. substance having the properties of an anhydride  $\text{BzCH}_2\text{CHPhCH}(\text{CO} \cdot \text{O} \cdot \text{CO})$  (I); hydrolysis regenerates the original acid, abs. alc.

gives the acid ester,  $\text{NH}_3$  the amidic acid. I is insol. in cold  $\text{Na}_2\text{CO}_3$  and on boiling it dissolves only slowly. Similar cryst. anhydrides were obtained from  $\text{BzCH}_2\text{CH}(\text{C}_6\text{H}_5\text{O}_2\text{CH}_2)\text{CH}(\text{CO}_2\text{H})_2$  and  $\text{AcCH}_2\text{CHPhCH}(\text{CO}_2\text{H})_2$ . According to the investigations of Staudinger, the anhydrides of substituted malonic acids decomp. on heating into  $\text{CO}_2$  and ketenes. The above anhydrides also lose  $\text{CO}_2$  on heating *in vacuo* but the products are not ketenes. That obtained from I is the unsatd. lactone  $\text{PhC} \cdot \text{CH} \cdot \text{CHPh} \cdot \text{CH}_2 \cdot \text{CO} \cdot \text{O}$  (II); I probably enolizes, then undergoes intramol.

acylation and the resulting acid ester yields II by loss of  $\text{CO}_2$ . II had already been prepd. by Vorländer and Knötzsch by boiling  $\text{BzCH}_2\text{CHPhCH}_2\text{CO}_2\text{H}$  (III) with  $\text{Ac}_2\text{O}$ , otherwise it would have been difficult to decide between the ketene,  $\text{BzCH}_2\text{CHPhCH} \cdot \text{CO}$ , and lactone structure for it, since the facts that it gives III with boiling dil.  $\text{Me}_2\text{CO}$ , its Me ester with MeOH and its amide with  $\text{NH}_3$  are reconcilable with both structures. It was thought that hydrogenation would give an aldehyde if the substance were a ketene and the satd. lactone if it is II, but there were obtained acid products, as described in the following abstr. [ $\alpha$ -Phenyl- $\beta$ -benzoyl-ethyl]malonic anhydride (I), m. 153-4°. Mono-Et ester, m. 122°, identical with the product obtained by half-sapon. of the di-Et ester. Amidic acid, m. 151° (vigorous decompn.).  $\delta$ -Hydroxy- $\beta$ , $\delta$ -di-phenyl- $\gamma$ -pentenic lactone (II), from I *in vacuo* at 175-205°, m. 88-9°,  $b_d$  245-50° (yield, 80-85%). Di-Et [ $\alpha$ -methylenedioxyphenyl- $\beta$ -benzoyl-ethyl]malonate (85% from  $\text{CH}_2\text{O}_2\text{C}_6\text{H}_5\text{CH} \cdot \text{CHBz}$ ,  $\text{CH}_2(\text{CO}_2\text{Et})_2$  and  $\text{NaOEt}$  allowed to stand 2 days in  $\text{MeOH} \cdot \text{C}_6\text{H}_6$ ), m. 94°. Free acid (IV), m. 159° (decompn.), easily becomes yellow in the air. Anhydride (yield, 10-5%), m. 192° (decompn.). Amidic acid, m. 145°.  $\delta$ -Hydroxy- $\beta$ -methylenedioxyphenyl- $\delta$ -phenyl- $\gamma$ -pentenic lactone, m. 94°, also obtained in 80% yield by boiling with  $\text{Ac}_2\text{O}$   $\beta$ -methylenedioxyphenyl- $\gamma$ -benzoylbutyric acid (V), m. 154-5°, which is prepd. by heating IV 1 hr. at 170°. Amide of V, from the lactone and alc.  $\text{NH}_3$ , m. 156°. [ $\alpha$ -Phenyl- $\beta$ -acetyl-ethyl]malonic anhydride (yield, 35-40%), m. 129°. Mono-Et ester, m. 106°, volatilizes partially undecompd. at 200° under 12 mm. but under 175 mm. it gives V. and K.'s  $\delta$ -hydroxy- $\beta$ -phenyl- $\gamma$ -hexenic lactone,  $b_d$  167°. C. A. R.

**Hydrogenation of some  $\delta$ -lactones.** A. MANNICH AND A. BUTZ. *Pharmazent. Inst., Berlin. Ber.* 62B, 461-3(1929).—The unsatd. lactones described in the preceding abstr. are readily hydrogenated in  $\text{Me}_2\text{CO}$  with  $\text{H}_2$  and Pd-charcoal. The reduction does not stop with the absorption of 1 mol.  $\text{H}_2$  but continues without any appreciable change in velocity until 2 mols. have been absorbed, yielding monobasic acids ( $\beta$ , $\delta$ -diphenylvaleric (I),  $\beta$ -methylenedioxyphenyl- $\delta$ -phenylvaleric (II)), also obtained in moderate yield from the  $\delta$ -ketonic acids by the Clemmensen method. If the hydrogenation is interrupted when only 1 mol.  $\text{H}_2$  has been absorbed, the products are not homogeneous. Besides the unchanged lactones and I or II, they contain chiefly dihydro intermediate products. These do not dissolve in  $\text{Na}_2\text{CO}_3$  but do so in hot  $\text{NaOH}$ , so that they may be considered as the satd. lactones; acids reppt. them from the alk. soln. and they are readily reduced further to I or II in  $\text{Me}_2\text{CO}$  with  $\text{H}_2$  and Pd-charcoal. The above reaction is not general; the lactone  $\text{MeC}:\text{CH}.\text{CHPh}.\text{CH}_2.\text{CO}.\text{O}$  cannot be hydro na-

ted with Pd and  $\text{H}_2$ ; the presence of a Ph group in the  $\delta$ -position seems to be a decisive factor. I (yield, 90%), m.  $109-10^\circ$ , easily sol. in  $\text{Na}_2\text{CO}_3$  and repptd. by acids.  $\beta$ , $\delta$ -Diphenyl- $\delta$ -hydroxyvaleric lactone, obtained in 3 g. yield, together with 1 g. I, from 5 g. of the unsatd. lactone hydrogenated until only 500 cc.  $\text{H}_2$  have been absorbed, m.  $117^\circ$ . II, m.  $138-9^\circ$ .  $\delta$ -Hydroxy- $\delta$ -phenyl- $\beta$ -methylenedioxyphenylvaleric lactone (1 g., together with 0.7 g. II, from 2.4 g. of the unsatd. lactone), m.  $132-3^\circ$ .

**Formation of methyl sodiochloromalonate and its reaction with iodine, with remarks on the stability of haloethanes.** ALFRED ECCLES. *Univ. Leeds. Proc. Leeds Phil. Lit. Soc., Sci. Sect.* 1, 356-9(1929).—Me sodiochloromalonate, prepd. by the interaction of  $\text{CHCl}(\text{CO}_2\text{Me})_2$  and  $\text{NaOMe}$  in  $\text{MeOH}$ , is a stable cryst. compd. contg. both Cl and Na. Treatment of this compd. with I did not yield  $[\text{CCl}(\text{CO}_2\text{Me})_2]_2$ . In this reaction,  $\text{Cl}_2$  splits out and the final product formed is  $[\text{C}(\text{CO}_2\text{Me})_2]_2$  (cf. *In-* gold, C. A. 22, 4501).

WALLACE R. BRODE

**Derivatives of caffeine.** VII. E. YOSHITOMI. *J. Pharm. Soc. Japan*, 49, 252-4 (1929).—In a previous publication (C. A. 20, 2826) in an attempt to prep. hydroxycaffeine by treating halocaffeine with *N* alkali under pressure, Y. obtained a new compd.  $\text{C}_{10}\text{H}_{13}\text{N}_5\text{O}_2$  (I). By repeating the expt. with halocaffeine and *N* KOH (1 mol.) in an autoclave at  $100-40^\circ$ , Y. obtained hydroxycaffeine and a new compd.  $\text{C}_8\text{H}_{11}\text{N}_5\text{O}_2$  (II), m.  $321^\circ$ . II contains an amino group, gives the murexide reaction, and also parabanic acid on oxidation. Y. claims this new compd. is methylamino-caffeine.

F. I. NAKAMURA

**The product of the condensation of glucose and *p*-phenetidine.** II. M. AMADORI. *Atti accad. Lincei* [6], 9, 68-73(1929).—In a previous paper (C. A. 20, 902) this reaction was studied, and it was shown that according to the method of prepn. employed, 2 products (A and B) were formed. A, m.  $118^\circ$ , was less stable and on prolonged heating was transformed into the more stable B, m.  $115^\circ$ . The constitution of these 2 was next to be detd. Neither has an  $\text{NH}_2$  group, so either 1 or 2 of the H atoms has reacted. In the first case the possible forms are

With 2 atoms, 4 possible forms are

Considering the *A* form, alkali gives variable values for the rotatory power, which, moreover, is different in  $\text{H}_2\text{O}$  or  $\text{EtOH}$ . In acid the final value is always  $30^\circ$ . Even if the soln. is acidified, then made alk., the value remains  $30^\circ$ , therefore, acid causes a permanent decompn. The analysis of *A* shows that in 2 g. there is present 1.2 g. glucose whose rotation is  $50^\circ$ . Therefore, the acid has decompd. *A* into  $\text{EtOC}_6\text{H}_4\text{NH}_2$  and glucose. This is also proved because if *A* is treated with  $\text{HNO}_2$  there is no reaction, but if  $\text{HCl}$  is first added, then the soln. is diazotized. *B*, however, is stable in acid, but decomp. to glucose and phenetidine in alkali. *A* is formed at lower temps., is less stable, is *l*-rotatory with mutarotation, and acids rapidly decomp. it to its constituents. This indicates the structure *A* and may exist in the  $\alpha$ - and  $\beta$ -modifications *B*, which is formed at higher temps., is stable toward acids, is *l*-rotatory with mutarotation and is easily decompd. by alkali. This indicates a constitution like a Schiff base, with stable bonds between the  $\text{NH}_2$  group and the glucose, according to the structures II and III. Here also there is a *cis-trans* equil. A. W. CONTIERI

The ceric acid reaction with particular reference to suberin. R. C. THOMAS. Ohio Agr. Expt. Sta. *Ohio J. Sci.* 28, 246-52 (1928).—Ceric acid obtained by macerating granulated cork in a mixt. of equal parts of concd. aq.  $\text{KClO}_3$  and  $\text{HNO}_3$  (d. 1.42) yields phellonic acid upon sapon. and repeated recrystn. EMIL KLARMANN

Higher hydrocarbons from methane. H. M. STANLEY AND A. W. NASII. Univ. Birmingham. *Nature* 122, 725 (1928).—Fischer's work (*C. A.* 23, 2694) on thermal decompn. of  $\text{CH}_4$  with formation of higher hydrocarbons is confirmed. R. J. H.

Higher hydrocarbons from methane. R. V. WHEELER. Univ. Sheffield. *Nature* 122, 773 (1928).—Production of com. yields of  $\text{C}_6\text{H}_6$  by pyrolysis of  $\text{CH}_4$  was proved at Sheffield two years ago.  $\text{C}_6\text{H}_6$  is probably produced from ethylene and butadiene, the formation of  $\text{C}_2\text{H}_4$  from  $\text{CH}_4$  taking place as follows:  $\text{CH}_3\text{H} \rightarrow \text{:CH}_2 + \text{H H}$  whereupon two  $\text{:CH}_2$  residues combine to form  $\text{C}_2\text{H}_4$ . R. J. HAVIGHURST

Higher hydrocarbons from methane. F. HURN CONSTABLE. *Nature* 122, 882 (1928); cf. *C. A.* 22, 4335; and preceding abstrs.—A graphite surface heated by an elec. current to temps. varying from  $800^\circ$  to  $1200^\circ$  and supported on China clay rods always led to a deposition of gas C on the exterior of the graphite film when acted upon by  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_2\text{H}_2$ ,  $\text{C}_3\text{H}_8$  and  $\text{H}$ . During the expts. with  $\text{CH}_4$  and  $\text{C}_2\text{H}_6$  these gases were suddenly removed and replaced by pressures of 5, 10, 20 and 50 cm of pure  $\text{H}$ . No change in pressure was noted, indicating that under these conditions the C deposited is incapable of combining with  $\text{H}$  at any appreciable speed.

The pyrolysis of methane. R. V. WHEELER AND W. L. WOOD. *Fuel in Science & Practice* 7, 535-9 (1928).—With an app. described by Williams (*C. A.* 20, 280), a study of the thermal decompn. of  $\text{CH}_4$  was made. The results obtained agree, in general, with those of Fischer (*C. A.* 23, 2694).  $\text{C}_6\text{H}_6$  is formed between  $875^\circ$  and  $1100^\circ$ , the optimum temp. (for the app. used) being about  $1050^\circ$  with a yield of 0.2 gal. per 1000 cu. ft. Quartz, porcelain and Cu reaction tubes were all without catalytic effect on the decompn. With an Fe tube only C and H are formed. Dila. of the  $\text{CH}_4$  with N has little effect on the yield of aromatic hydrocarbons obtained at  $1000^\circ$  but dila. with H rapidly decreases the yields. The app. is described and illustrated. D. A. REYNOLDS

**Highly polymerized\* compounds. XVI. Polymerization of  $\alpha$ -methylstyrene.** H. STAUDINGER AND F. BREUSCH. Univ. Freiburg i. Br. *Ber.* 62B, 442-56 (1929); cf. *C. A.* 23, 2950.—Polymerization of styrene in the cold gives a eucolloidal polystyrene with a mol. wt. around 100,000; at 240° and with catalysts ( $\text{SnCl}_4$ ) are formed hemicolloids with an av. mol. wt. of 1000-10,000, consisting of mixts. of polymeric homologous products from which no homogeneous substances can be isolated because the properties of neighboring members of the series are too similar to each other. The polystyrenes are built up by addn. to an activated mol. of other styrene mols. to form long chains; the end valences of which finally sat. themselves by ring formation. The polystyrenes are therefore polymembered rings. With  $\alpha$ -methylstyrene,  $\text{PhMeC:CH}_2$  (I), have been made a no. of observations which confirm these views. I does not polymerize either on long standing or on illumination so that no eucolloidal poly-I can be obtained. On heating and with catalysts polymerization is much more difficult than with styrene. Tiffeneau with concd.  $\text{H}_2\text{SO}_4$  obtained a dimer (II), m. 52°, which is a diphenyldimethylcyclobutane, and Klages with  $\text{H}_3\text{PO}_4$  obtained an unsatd. product, probably  $\text{PhCMe:CHCH}_2\text{CHMePh}$  or  $\text{PhCHMeCH:CHCHMePh}$ . Such unsatd. polymers have been obtained by S. and B. at high temps. and with Florida earth,  $\text{TiCl}_4$  and  $\text{BCl}_3$ . With  $\text{SnCl}_4$  without diln. very vigorous polymerization takes place with formation of satd. polymers, including, besides II, higher products, although in small yield; with solvents practically only II is formed. The polymerization tendency of I is so much smaller than that of styrene that the highest polymer contains only 8 members in its ring and the individual polymers differ enough in their properties to have made it possible to isolate all 8 of the series mono- to octamer in pure or approx. pure form. Below are given their constns. in the order monomer, dimer, etc.:  $b_{0,1}$  45, 118-20, 172-8, 208-12, 240-4, 275-85, 312-22, 345-60°; soly. in MeOH (cc. required to dissolve 1 g.), miscible, 20.4, 21.7, 74.8, 203, 625, 2400, 25,000; viscosity (outflow time of a soln. of 118 g. in 1 l.  $\text{C}_6\text{H}_6$ ;  $t_0 = 40$  sec.), 41, 42.5, 44, 46.2, 49, 52, 56.7, 63.1; d. of amorphous prepn., 0.9044, 1.0038, 1.0455, 1.0594, 1.0624, 1.0657, 1.0671, 1.0684;  $n_D^{20}$ , 1.5330, 1.5633, 1.5842, 1.5934, 1.5960; 1.6050, 1.6010, 1.6120; softening range, —, —32° to —24°, —3° to 9°, 38-48°, 60-8°, 98-108°, 125-33°, 165-72°. The dimer and tetramer have also been obtained in cryst. form; their m. p. and d. are considerably higher than for the amorphous products, viz.: dimer, 52°, 11183; tetramer, 127-9°, 1.1452. It is a striking fact that the dimer should be homogeneous, for there are theoretically possible the 2 structural isomers  $\text{PhMeC:CH}_2\text{:CMePh:CH}_2$  and  $\text{PhMeC:CH}_2\text{:CH}_2\text{:CMePh}$  and a stereoisomer of each

of these; the addn. of the mols. of I to each other therefore proceeds in only 1 direction. Whether the higher polymers are homogeneous or mixts. of stereoisomers cannot be decided as long as they have not been obtained in cryst. form. As shown by the above data, the phys. properties of the polymers of I change with the degree of polymerization. Some of the constns. of mixts. are the mean of those of the components (d., viscosity of solns.), others are lower (liquefaction temp.); in general, the degree or av. degree of polymerization of any prepn. can be deduced from the constns. for the pure substances and mixts. of them. These results confirm the view that the more highly polymerized styrenes, up to the eupolystyrene with an av. polymerization degree of 1000, are not merely assocn. products. It is probable that the eucolloidal polystyrene, like rubber, is made up of extraordinarily large rings, a fact of great significance for their phys. properties, for substances built up of thread mols. (*Fadenmoleküle*), like guttapercha and cellulose, have different properties; by a parallel arrangement of their mols. they cryst. much more readily than polymeric substances with a cyclic structure. In the prepn. of I the dehydration of the  $\text{Me}_3\text{PhCOH}$  is best effected by boiling 1 hr. in an equal wt. of  $\text{Ac}_2\text{O}$ , distg. off the I,  $\text{Ac}_2\text{O}$  and  $\text{AcOH}$  *in vacuo* and repeating the process several times with the unchanged carbinol, about 90% of which can finally be converted into I. For the polymerization, 250 g. I was treated with 20 g.  $\text{SnCl}_4$ ; much heat was evolved and the mixt. boiled; after 24 hrs. it was taken up in 300 cc.  $\text{C}_6\text{H}_6$ , washed with dil. HCl and NaOH, concd. to 0.5 vol., dried with  $\text{CaCl}_2$  and slowly dropped into 1 l. MeOH which gave about 20 g. of curdy flocks. The supernatant liquid on fractionation under 0.1 mm. yielded 180, 20, 11 and 4 g. of the di-, tri-, tetra- and pentamer, resp., and from the MeOH ppt. were obtained another 2 g. of the pentamer and 6, 4 and 6 g. of the hexa-, hepta- and octamers, resp. The unsatd. dimer,  $b_{0,1}$  117-20°, mol. wt. in  $\text{C}_6\text{H}_6$  230, in camphor 219,  $d_{20}$  0.9889,  $n_D^{20}$  1.5677, soly. in MeOH 1:6.8. C. A. R.

Double salts of phenyliodonium iodide with mercuric chloride and the formation of diphenyliodonium salts by decomposition of these double salts. A. N. NESMEYANOV.

Univ. of Moscow. *Z. anorg. allgem. Chem.* 178, 300-8 (1929).—From  $\text{PhN}_2\text{Cl}$  and  $\text{MeOH}$ ,  $\text{K}_2\text{HgI}_4$  pptd.  $\text{PhN}_2\text{HgI}_4$  (I), m.  $63-4^\circ$  (decompn.) I heated with aq. HI gives  $(\text{PhN}_2)_2\text{HgI}_4$  (II), m.  $59.5-60^\circ$ . By covering with  $\text{Me}_2\text{CO}$ , II is decompd. to I,  $\text{N}_2$  and  $\text{PhI}$ . Addn. of  $\text{PhN}_2\text{Cl}$  soln. to  $\text{K}_2\text{HgI}_4$  soln. gave I of lesser purity. Decompn. of I at room temp. gave by  $\text{Et}_2\text{O}$  extn. a product, b.  $188-90^\circ$ , and  $\text{Ph}_2\text{I}$ .  $\text{Me}_2\text{CO}$  extn. gave about 10% of  $\text{Ph}_2\text{IHgI}_2$  (III), m.  $171.5^\circ$ . Hot 50% KI converts III into  $\text{Ph}_2\text{II}$  and  $(\text{Ph}_2\text{I})_2\text{Hg}$  (IV). IV decomp. in 5 days to  $\text{PhI}$  and a small amt. of III.  $\text{Ph}_2\text{II}$  and  $\text{HgI}_2$  combine at  $100^\circ$  to give III. Addn. of KI to a soln. of  $\text{PhN}_2\text{Cl}$  gave no solid  $\text{Ph}_2\text{II}$  and not over 0.27% in soln. The solubilities of  $\text{Ph}_2\text{II}$  in 100 g.  $\text{H}_2\text{O}$  and 100 g.  $\text{PhI}$  are 0.0304 g. and 0.009 g., of  $\text{Ph}_2\text{II}_2$  are 0.015 g. and 0.0486 g. The formation of iodonium compds. without oxidation is analogous to formation of  $\text{R}_4\text{NX}$  from  $\text{R}_3\text{N}$  and  $\text{RX}$ . F. D. S.

**Preparation of homopiperonylamine.** Y. TANAKA AND T. MIDZUNO. *J. Pharm. Soc. Japan* 49, 255-60 (1929).—Condensation of piperonal (30 g.) with  $\text{MeNO}_2$  (13 g.) in  $\text{EtOH}$  (cf. Rosenmund, C. A. 5, 893) gave *methylenedioxy- $\omega$ -nitrostyrene* (I), m.  $159-60^\circ$  (yield 93.2%). Electrolytic reduction of I (cf. Takamoto, C. A. 22, 2354) gave *homopiperonylamine* (II) (yield 76.19%). Salts of II: oxalate, decomp.  $218-9^\circ$ ;  $\text{HCl}$  salt, m.  $208^\circ$ ; picrate, m.  $175^\circ$ ; Pt salt, decomp.  $220^\circ$ . F. I. NAKAMURA

**Compounds of tetryl with hydrocarbons.** N. N. EFREMOV AND A. M. TIKHOMIROVA. *Ann. inst. anal. phys.-chim. (Leningrad)* 4, 92-117 (1928); cf. C. A. 21, 3802.—Tetryl, m.  $126.8^\circ$ , forms equimol. compds. with  $\text{C}_{10}\text{H}_8$  and acenaphthene. Similar compds. with phenanthrene, fluorene, and retene easily decomp. on melting. Picramide, 2,4-dinitroaniline, picryl chloride, trinitroanisole, 2,4,6-trinitro-*m*-xylene and camphor form eutectics of low m. p. but no definite compds. The following eutectics were found: with  $\text{C}_{10}\text{H}_8$ , m.  $80.1^\circ$ , at  $70.8^\circ$  (15 mol. % of tetryl) and at  $82.5^\circ$  (57.5 mol. %),  $\text{C}_{10}\text{H}_8$  -  $\text{C}_7\text{H}_7\text{N}_3\text{O}_8$ , m.  $86.4^\circ$ , at  $75.7^\circ$  (41.5 mol. %),  $\text{C}_{10}\text{H}_8$  -  $\text{C}_7\text{H}_7\text{N}_3\text{O}_8$ , decomp.  $77.5^\circ$  (43.3 mol. %); with retene, m.  $95.2^\circ$ , at  $56.7^\circ$  (25.6 mol. %),  $\text{C}_{10}\text{H}_8$  -  $\text{C}_7\text{H}_7\text{N}_3\text{O}_8$ , decomp.  $61.7^\circ$  (29.5 mol. %); with picramide, m.  $184.2^\circ$ , at  $110.8^\circ$  (86.1 wt. %); with 2,4-dinitroaniline, m.  $176^\circ$ , at  $98.8^\circ$  (80.7 wt. %); with picryl chloride, m.  $81.2^\circ$ , at  $57.8^\circ$  (39.4 wt. %); with trinitroanisole, m.  $63.8^\circ$ , at  $22.8^\circ$  (29.5 wt. %); with 2,4,6-trinitro-*m*-xylene, m.  $180.2^\circ$ , at  $110.8^\circ$  (76.6 wt. %); with camphor at  $102.9^\circ$  (73.3 wt. %). V. K.

**Synthesis of thiocarbanilide.** M. N. UBDINOV, N. S. DROZDOV AND N. A. STEPANOV. *J. Chem. Ind. (Moscow)* 6, 37-9 (1929).—Thiocarbanilide prepn. by the method of Marks and Clark (Eng. patent 244,070 of 1926) runs smoothly and the yield is 86-8%. Expts. undertaken by D. and S. to find the most favorable operating conditions have shown that the relative proportion of  $\text{CS}_2$  and  $\text{PhNH}_2$  taken has a great influence on the yield. The app. consisted of an asbestos-covered tightly stoppered glass cylinder of 750 cc. capacity; a stirrer, a separatory funnel and a thermometer were passed through the stopper. The operating method consisted in introducing aq.  $\text{NaOH}$  into the cylinder at  $25^\circ$ , setting the stirrer into action and adding through the separatory funnel  $\text{PhNH}_2$  soln. in  $\text{CS}_2$  at  $25^\circ$ . The asbestos covering served as a thermoinsulator, making it possible to follow the temp. variations of the reaction mass. The temp. spontaneously went up, reached a max. and dropped to  $40^\circ$ , at which latter point the reaction was considered as ended, the asbestos covering was taken off and the cylinder was cooled to  $15^\circ$  by immersion in cold  $\text{H}_2\text{O}$ . The stirring was continued 30 mins. after the temp. of  $15^\circ$  was reached, then the reaction mass was dild. with an equal volume of  $\text{H}_2\text{O}$  to prevent pptn. of  $\text{Na}_2\text{CS}_3$  together with  $\text{CS}(\text{NHP})_2$ , and the ppt. of the latter was filtered with suction, washed first with  $\text{H}_2\text{O}$ , then with 10-15 cc. 10%  $\text{HCl}$  to transform the aniline into its salt, then again with  $\text{H}_2\text{O}$ , and finally the carbanilide was dried. In all these expts. the total quantity of the reaction mixt. taken was the same, viz., 400 g., the relative quantity of alkali represented 115% of the theoretical calcd. on  $\text{CS}_2$ , but the relative proportions of  $\text{CS}_2$  and  $\text{PhNH}_2$  were varied in each expt. The results of 11 expts. were tabulated and a diagram was drawn which expressed the influence of the proportion of the components on the yield and on the extent of the exothermic effect. The data obtained permit of concluding that,  $\text{CS}_2$  being up to 10-20% in excess, the yield increases to 94%; a  $\text{CS}_2$  excess of between 20 and 40% does not further affect the yield, and an excess of more than 40% decreases the yield as a result of the reaction  $\text{PhNH}_2 + \text{CS}_2 = \text{PhN}:\text{C}:\text{S} + \text{H}_2\text{S}$ . An excess of  $\text{PhNH}_2$  adversely affects the  $\text{CS}(\text{NHP})_2$  yield on account of the tendency to triphenylguanidine formation. The exothermic max., which is about  $77^\circ$ , is registered when the  $\text{CS}_2$  excess is between 10-20%, i. e., when the yield is best.

BERNARD NELSON

**Allylphenylthiourea as a solvent.** V. P. SHISHOKIN. *Ann. inst. anal. phys.-chim. (Leningrad)* 4, 195-224(1928).—CS(NHC<sub>3</sub>H<sub>5</sub>)(NHPh) forms compds. with CHCl<sub>3</sub>, paraldehyde, CCl<sub>3</sub>CO<sub>2</sub>H and Ac<sub>2</sub>O, and probably also with AcOH, C<sub>6</sub>H<sub>5</sub>Br<sub>3</sub>, PhNO<sub>2</sub>, EtOH, MeOH, allyl mustard oil, benzene, toluene and C<sub>10</sub>H<sub>8</sub>. No compds. are formed with aniline, o-nitroaniline, and Ph<sub>2</sub>NH. Exptl. data are given in detail. By applying the laws of Shreder-Le Chatelier (*Gornui Zhurnal* 1890, No. 11, 272; *Compt. rend.* 118, 638(1894)) and Hildebrand-Mortimer (*C. A.* 10, 2426; 11, 3146; 13, 1663; 15, 6; 16, 2803; 17, 2216) the heat of fusion of allylphenylthiourea was calcd. as 6400-6960 cal. per mol. which is close to the exptl. value of 6600 cal. The internal pressure of allylphenylthiourea must be close to that of aniline, and of allyl mustard oil to that of PhNO<sub>2</sub>.

V. KALICHEVSKY

Further communication on my method of thiocyanating organic compounds. H. P. KAUFMANN. Univ. Jena. *Ber.* 62B, 390-1(1929); cf. *C. A.* 22, 2166.—In the original method of thiocyanating org. compds. with the (SCN)<sub>2</sub> liberated from inorg. thiocyanates with Cl or Br, acid solns. were used to impede the hydrolysis of the (SCN)<sub>2</sub>. Many substances do not dissolve well in acids, large quantities of alkali are required to neutralize the acid and, finally, the acid favors secondary transformations of the resulting thiocyanates, but it has now been found, with W. OEHNING and E. WEBER, that the AcOH, HCO<sub>2</sub>H, etc., can be replaced by indifferent solvents (MeOH, Me<sub>2</sub>CO, AcOEt, MeOAc, etc.). MeOH is especially satisfactory in some cases; by satg. it with the corresponding alkali halide, it can be protected against any attack by the Cl or Br. Numerous examples of the application of the modified process in the prepn. of therapeutically valuable S compds. are described in a paper, now in press, in *Arch. Pharm.* Here is reported only the thiocyanation of PhNH<sub>2</sub>: 14 g. PhNH<sub>2</sub> and 37 g. NaSCN in 90 cc. cold MeOH are treated dropwise with 8.5 cc. Br in 30 cc. cold MeOH (satd. with NaBr), poured into H<sub>2</sub>O and neutralized with Na<sub>2</sub>CO<sub>3</sub>, giving 97% of p-NCSC<sub>2</sub>H<sub>4</sub>NH<sub>2</sub>, m. 97° after 1 crystn. from H<sub>2</sub>O.

C. A. R.

The forced reaction between some hydrocarbons and organomagnesium halides. HENRY GILMAN AND JOHN A. LEERMAKERS. Chem. Dept., Ames, Iowa. *Rec. trav. chim.* 48, 577-9(1929).—The Grignard reagent will react with some hydrocarbons, particularly with those having a true acetylenic group; the present paper deals with the reaction between Grignard reagents and hydrocarbons possessing H atoms less acidic than those in the :CH group. The procedure followed was to reflux the Grignard compd., PhCH<sub>2</sub>MgCl or EtMgBr, with di- or triphenylmethane in a mixt. of ether and benzene, toluene or xylene at temps. ranging from 60-128° for from 3-7 hrs. After the usual decompn. of the reaction mixt., after having converted the Grignard compd. with CO<sub>2</sub> into the corresponding acid, a careful search was made for diphenyl- and triphenylacetic acid, which, however, could not be detected in any of the expts. Moreover, the hydrocarbon tested was recovered in every expt. in a very high percentage and in a state of high purity, whereas with Ph<sub>3</sub>CH not a trace of triphenylmethyl peroxide could be detected. These results show that under conditions of protracted refluxing and elevated temps. di- and triphenylmethane do not react with PhCH<sub>2</sub>MgCl and EtMgBr.

C. F. VAN DUIN

**Halogen elimination from halogenated eleostearic acid. Identification of phthalic acid by the fluorescein reaction.** D. HOLDE, W. BLEYBERG AND M. A. AZIZ. *Z. angew. Chem.* 42, 283-4(1929).—Unsatd. acids which have been treated with excess IBr in glacial AcOH (Hanus reagent) and the excess titrated with Na<sub>2</sub>S<sub>2</sub>O<sub>4</sub>, spontaneously liberate the added halogen (cf. Holde, *C. A.* 23, 2049 and Kaufmann and Lutenberg, *C. A.* 23, 3360). Expts. were made to det. if the loss of halogen in the case of dibromo-α-eleostearic acid (I) gives an aromatic acid which can be oxidized with CrO<sub>3</sub> to phthalic acid (II) as follows:

The oxidation product when heated for 3 min. with resorcinol (III) and 1 drop H<sub>2</sub>SO<sub>4</sub> at 160° gave a fluorescent soln. in dil. alkali but this was not due to the presence of II since many other compds., viz., aldehydes, ketones, chlorides, mono- and dibasic acids, and esters give condensation products with III which yield fluorescent alk. solns. (acetfluorescein, succinylfluorescein, etc.). When making a test for II it is essential that no H<sub>2</sub>SO<sub>4</sub> be added and that the condensation with III be brought about at 25-10° for 3 mins. Whether the loss of halogen from I gives oxygenated or polymerized prod-

ucts was not detd. and further investigations are under way to det. the course of this reaction. N. A. LANGE.

The action of arsenic acid and derivatives upon the nitrophenols. OCTORINO RODOLFO PEPE. *Rev. facultad cienc. quim. (Univ. La Plata)* 5, Pt. I, 105-79 (1928).—P. gives first a review of the different methods of combining As with org. radicals, then a description of how to prep. his starting material. His expts. aim at the application of the reaction of Béchamp for the prepn. of *hydroxynitrophenylarsonic acid*,  $o\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$  and  $\text{H}_2\text{AsO}_4$  were brought in contact under varying conditions, then the salts of Na, K and  $\text{NH}_4$  used,  $\text{H}_2\text{As}_2\text{O}_7$  was tried and the expts. repeated in the presence of  $\text{H}_2\text{SO}_4$ ,  $\text{P}_2\text{O}_5$  and  $\text{Ac}_2\text{O}$ . The result of all these expts. was negative. Some tests were made to control the methods of isolation of the expected products and their identification. The 4,3- $\text{HO}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$  is decomposed partially when heated in the presence of  $\text{H}_2\text{AsO}_4$  and  $o\text{-O}_2\text{NC}_6\text{H}_4\text{OH}$ . The different  $\text{HO}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{AsO}_3\text{H}_2$  give with Br in  $\text{H}_2\text{O}$  the same compds. as the corresponding nitrophenols and in this way cannot be distinguished. A. E. MEYER.

Mercuration of benzene derivatives. B. KALINOWSKI. *Roczniki Chem.* 9, 131-47 (147-8 French) (1929).—1-Bromobenzene-2,4-dimercuric acetate (I),  $\text{C}_{10}\text{H}_5\text{BrO}_4\text{Hg}_2$ , m.  $223^\circ$ , was obtained by heating PhBr with  $\text{Hg}(\text{OAc})_2$  in a closed tube to  $120^\circ$ . I in AcOH gives with NaCl a white ppt. of 1-bromobenzene-2,4-dimercuric chloride,  $\text{C}_6\text{H}_5\text{BrCl}_2\text{Hg}_2$ , m.  $232^\circ$ . From  $p\text{-C}_6\text{H}_4\text{Br}_2$  in a similar way at  $140^\circ$  1,4-dibromobenzenedimercuric acetate,  $\text{C}_{10}\text{H}_3\text{O}_4\text{Br}_2\text{Hg}_2$ , m.  $157\text{--}8^\circ$ , was obtained; the position of the Hg groups, however, could not be detd.  $\text{Hg}(\text{OAc})_2$  in hot AcOH gave with the soln. of *o*-nitrophenol a yellow ppt., *o*-nitrophenol-4,6-dimercuric acetate,  $\text{C}_{10}\text{H}_5\text{O}_7\text{NHg}_2$  (II), triangular crystals which exploded on heating.  $\text{I}_2\text{KI}$  with II in 20% AcOH gave the known 4,6-diiodo-*o*-nitrophenol, m.  $97.5^\circ$ , whereby the position of Hg was detd. On hydrolysis of II, however, the mercuri-*aci-o*-nitrophenol anhydride, (Hantzsch, *Ber.* 39, 1115 (1906)) was not obtained, but 2-nitrophenol-4,6-dimercuric anhydride,

a dark yellow substance, insol. in any solvent. In an analo-

gous way *p*-nitrophenol gave a greenish yellow ppt., 4-nitrophenol-2,6-dimercuric acetate,  $\text{C}_{10}\text{H}_5\text{O}_7\text{NHg}_2$ ; white needles from 20% AcOH, rhombic from 40% AcOH, exploding on heating to  $200^\circ$ . The product of hydrolysis, 4-nitrophenol-2,6-dimercuric anhydride,  $\text{C}_6\text{H}_3\text{O}_4\text{NHg}_2$ , is a white, insol. substance decomp.  $220^\circ$  without melting. *m*-Nitrophenol gives yellow, rhombic crystals of 3-nitrophenol-2-monomercuric acetate (anhydride,  $\text{C}_6\text{H}_3\text{O}_3\text{NHg}$ ),  $\text{C}_6\text{H}_7\text{O}_3\text{NHg}$ , m.  $210^\circ$ , the structure of which was detd. through 2,3- $\text{I}(\text{O}_2\text{N})\text{C}_6\text{H}_3\text{OH}$ , m.  $136^\circ$ . Other mercuric derivs. of  $\text{C}_6\text{H}_5$  were prepd.: 2,4-dinitro-1-phenol-6-monomercuric acetate (anhydride,  $\text{C}_6\text{H}_3\text{O}_4\text{N}_2\text{Hg}$ ),  $\text{C}_6\text{H}_5\text{O}_7\text{N}_2\text{Hg}$ , yellow, insol. crystals; 2,6-dinitrophenol-4-monomercuric acetate,  $\text{C}_6\text{H}_5\text{O}_7\text{N}_2\text{Hg}$ , white crystals exploding on heating; 2-chlorophenol-4,6-dimercuric acetate,  $\text{C}_{10}\text{H}_5\text{O}_6\text{ClHg}_2$  (anhydride,  $\text{C}_6\text{H}_3\text{O}_5\text{ClHg}$ , yellow crystals), white needles, decomp. on heating; 3-chlorophenoldimercuric acetate (anhydride,  $\text{C}_6\text{H}_3\text{O}_5\text{ClHg}_2$ , yellow crystals),  $\text{C}_{10}\text{H}_5\text{O}_6\text{ClHg}_2$ , white needles, decomp. at  $270^\circ$ ; 4-chlorophenol-2,6-dimercuric acetate (anhydride,  $\text{C}_6\text{H}_3\text{O}_5\text{ClHg}$ ),  $\text{C}_{10}\text{H}_5\text{O}_6\text{ClHg}_2$ , white needles, decomp. at  $270^\circ$ . The rule that Hg does not enter into the *m*-position of benzene holds throughout in all these cases. J. K.

Organic sulfur compounds. XII. Formation of mercaptoles by the action of aliphatic diazo compounds on disulfides (preliminary communication). A. SCHÖNBERG O. SCHÜTZ AND J. PETER. *Tech. Hochschule Charlottenburg. Ber.* 62B, 440-1 (1929); cf. *C. A.* 23, 2708.—It is known that the S.S union of certain aromatic disulfides is ruptured by "free" methyl radicals:  $\text{ArSSAr} + 2\text{Ph}_3\text{C} = 2\text{ArSCPh}_3$ . It has now been found that a similar reaction can be effected with "free" methylene radicals. E. g., if diphenyldiazomethane is heated it is generally accepted that it first decomp. into  $\text{N}_2$  and "free"  $\text{Ph}_2\text{C}$  which then stabilizes itself, forming  $\text{Ph}_2\text{C}:\text{CPh}_2$  or  $(\text{N}:\text{CPh}_2)_2$ , depending on the conditions. If, however, the decompn. is effected in boiling  $\text{C}_6\text{H}_6$  in the presence of  $\text{Ph}_2\text{S}_2$  there is formed  $\text{Ph}_2\text{C}(\text{SPh})_2$ . The mercaptole (yield, over 50%) m.  $138^\circ$ , dissolves in concd.  $\text{H}_2\text{SO}_4$  with red-brown color; plunged in a m. p. tube for 15 sec. into a bath at  $230^\circ$  it forms a deep blue-green melt because at this temp. it decomp. into  $\text{Ph}_2\text{CS}$ . C. A. R.

Congo copal oil (preliminary communication). L. WESTENBERG. *Krommenie*

Holland. *Rec. trav. chim.* **48**, 580-2(1929).—The pyrogenetic decompn. of Congo copal at about 300° leads to the formation of Congo copal oil, which has not been investigated up to the present moment. A sepn. into the constituents by fractional distn. could not be carried out, only 2 principal fractions being obtained, b. 240-60° and 170-80°, the first one was the larger one and was very reactive toward several reagents, however it was impossible to obtain a cryst. deriv. in a pure condition. On heating Congo copal oil with 40% S at 250° until H<sub>2</sub>S is no longer evolved, a reaction product is obtained, which, after distn. in a vacuum, yields a hydrocarbon, which easily gives a red *picrate*, m. 139°. This *picrate* is identical with the *picrate*, m. 139°, obtained by Ruzicka and his co-workers, from Manilla copal (*C. A.* **21**, 906), and gives, on treatment with alkali, a hydrocarbon C<sub>13</sub>H<sub>14</sub>, m. 26°, b<sub>760</sub> 295°. The oxidation of this hydrocarbon with CrO<sub>3</sub> in boiling AcOH gives a small amount of an acid C<sub>13</sub>H<sub>12</sub>O<sub>4</sub>, m. 204°, which was not investigated further, and a neutral compd. (C<sub>6</sub>H<sub>4</sub>O)<sub>n</sub>, pale yellow crystals, m. 69°. This substance does not liberate I from KI, nor is it reduced by SnCl<sub>2</sub>, although its compn. agrees with that of ethylbenzoquinone or one of the xyloquinones. The m. p. is fairly in agreement with that of *m*-xyloquinone (72-73°) but a direct comparison could not be carried out.

C. F. VAN DUIN

Preparation of benzaldehyde from toluene using oxides of manganese as oxidizing agents. I. KIYOAKI KAKUTANI AND NAOTOSHI YAMAGUCHI. *Repts. Imp. Ind. Research Inst. Osaka, Japan* **9**, No. 11, 1929.—In order to study the effect of MnO<sub>2</sub>, Mn<sub>2</sub>O<sub>3</sub>, and Mn<sub>3</sub>O<sub>4</sub> as oxidizing agents on the prepn. of BzH from PhMe, K. and Y. prepd. the above oxides by the following methods: (A) by heating Mn(NO<sub>3</sub>)<sub>2</sub>, (I), (B) by treating I with KClO<sub>3</sub>, (C) by treating MnSO<sub>4</sub>, (II) with Cl gas, and (D) by treating II with KMnO<sub>4</sub>. The expt. was carried out in a 3-necked flask provided with a thermometer, reflux condenser and a stirrer. The flask was immersed in a water bath. The product was analyzed by the usual methods. Since MnO<sub>2</sub> prepd. by (1) and the natural pyrolusite have similar properties the following factors were especially studied: effect of reaction time, reaction temp., concn. of H<sub>2</sub>SO<sub>4</sub>, quantity of PhMe used, method of adding the oxide, and quantity of oxide used. In general Mn<sub>2</sub>O<sub>3</sub> is the best oxidizing agent followed by MnO<sub>2</sub> and under the proper conditions its oxidizing power is above 70%. The oxidizing power of an oxide is influenced by its method of prepn. This may be due to its phys. properties. The oxidizing power of MnO<sub>2</sub> prepd. by (A) under any conditions was very poor, while that of MnO<sub>2</sub> prepd. by (B), (C) and (D) under proper conditions was about 40%. The results of further investigation will be published in the future.

F. I. NAKAMURA

Protocatechualdehyde and its simplest ethers. C. JUNGE. *Göttingen. Parfumer* **3**, 35-6(1929).—A recapitulation of their properties and constitution. P. E.

Synthesis of 3-methoxy-4-ethoxy-6-ethylbenzoic acid. T. KONDO AND S. TANAKA. *J. Pharm. Soc. Japan* **49**, 263-7(1929).—In a previous publication (*C. A.* **23**, 2979) by treating *o*-MeOC<sub>6</sub>H<sub>4</sub>OEt with AcCl (1 mol.) K. and T. obtained two Ac derivs., MeO(EtO)C<sub>6</sub>H<sub>3</sub>Ac (I<sub>1</sub>), m. 79°, and (I<sub>2</sub>) with lower m. p. Reduction of the mixt. of I<sub>1</sub> and I<sub>2</sub> with Zn-Hg and HCl gave 2 compds., MeO(EtO)C<sub>6</sub>H<sub>3</sub>Et (II<sub>1</sub>), b<sub>1</sub> 107°, and (II<sub>2</sub>), b<sub>1</sub> 95°. Acetylation of II<sub>1</sub> gave Et(MeO)(EtO)C<sub>6</sub>H<sub>3</sub>Ac (III), m. 81.5-2.5°. III treated with NaOI gave 3-methoxy-4-ethoxy-6-ethylbenzoic acid, m. 133-4°. F. I. NAKAMURA

The saponification of nitriles with orthophosphoric acid. S. C. J. OLIVIER. *Agronomical Univ., Wageningen. Rec. trav. chim.* **48**, 568-70(1929).—Previously Berger and Olivier published a new method for the sapon. of nitriles and amides, *viz.*, by means of H<sub>3</sub>PO<sub>4</sub> (*C. A.* **22**, 239); the present paper deals with the case of 2,4-Br<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CN, which was prepd. from AcNHPH as follows: PhNHAc was brominated to 2,4-Br<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NHAc (cf. Montagne, *C. A.* **7**, 1178); after sapon. with alc. KOH the 2,4-Br<sub>2</sub>C<sub>6</sub>H<sub>3</sub>NH<sub>2</sub> was converted into 2,4-dibromobenzonitrile, m. 93-4°, by means of the Sandmeyer reaction (cf. Montagne, *C. A.* **7**, 1178). Several sapon. expts. were carried out with this nitrile, each time 2 g. being heated with 25 cc. H<sub>3</sub>PO<sub>4</sub> of varying strength at 160-70° for 2 hrs. With 93.5% H<sub>3</sub>PO<sub>4</sub> the nitrile remained unchanged, with 100% acid the transformation was nearly complete and the same result was obtained with H<sub>3</sub>PO<sub>4</sub> contg. free P<sub>2</sub>O<sub>5</sub>. It thus appears that H<sub>3</sub>PO<sub>4</sub> is the more suitable for the sapon. of nitriles the less water it contains; this fact is explained by the greater soly. of the nitrile in the stronger acid and by an easier compd. formation under the latter conditions (cf. O. and B., *l. c.*). The water necessary for the sapon. is given off by the H<sub>3</sub>PO<sub>4</sub>, which begins to lose water at 160°. The possibility that an addn. compd. is formed, which is decompd. with the formation of 2,4-Br<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H, on treatment of the reaction product with water, is excluded by the fact that the Br<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CO<sub>2</sub>H sublimes during the heating into the neck of the flask. The 2,4-dibromobenzoic acid, thus obtained, m. 173.5-4.5°; yield 90%.

C. F. VAN DUIN

The action of mustard oils and hydrogen chloride upon polyhydric phenols. P. KARRER AND ERNST WEISS. Chem. Inst. Univ. Zurich. *Helv. Chim. Acta* 12, 554-7 (1929).—The condensation of polyhydric phenols with mustard oils in the presence of HCl results in the formation of thio-acid amide derivs. Directions are given for the prepn. of the following new compds.: *ethylamide of thioresorcylic acid*,  $\text{EtNHCS}\cdot\text{C}_6\text{H}_3(\text{OH})_3$ , m.  $96^\circ$  (16 g. from 12 g.  $\text{EtNCS}$  and 15 g. resorcinol); *ethylamide of phloroglucinolthiocarboxylic acid*,  $\text{EtNHCS}\cdot\text{C}_6\text{H}_2(\text{OH})_3$ , m.  $152^\circ$ ; *allylamide of pyrogallolthiocarboxylic acid*, m.  $206^\circ$  (decompn.); *anilide of thioresorcylic acid*, m.  $176^\circ$  (25 g. from 25 g.  $\text{PhNCS}$  and 20 g. resorcinol); *anilide of  $\alpha$ -naphtholthiocarboxylic acid*, m.  $206^\circ$  (9.5 g. from 18 g.  $\text{PhNCS}$  and 20 g.  $\alpha$ -naphthol);  *$\beta$ -naphthylamide of thioresorcylic acid*, m.  $177-9^\circ$ . L. F. AUDRIETH

Question of "quinoid" tautomerism. Chlorination of *p*-nitrobenzyl cyanide. VSEVOLOD NEKRASOV AND A. V. SÓKOLOV. Lab. S. S. Nametkin, Moskau. *Ber.* 62B, 463-6(1929).—Halogens attack  $\text{PhCH}_2\text{CN}$  not only at high temps. and in the light but also in the cold in the presence of catalysts exclusively in the side chain, giving  $\text{PhCHXCN}$ . Only one H atom of the  $\text{CH}_2$  group is substituted;  $\text{PhCCl}_2\text{CN}$  is obtained by other methods. N. and S. have now found that *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CH}_2\text{CN}$  (I) reacts quite vigorously with Cl at high temps. and in strong light, smoothly yielding *p*-nitrophenyldichloroacetomitrile (II), an oil with no lachrymatory properties. On oxidation in alk. soln. it yields *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ . It is sapond. only very slowly by aq. acids; stronger reagents (HBr,  $\text{H}_2\text{SO}_4$ ) also split off the side chain, giving  $\text{O}_2\text{NC}_6\text{H}_4\text{CO}_2\text{H}$ , but with HCl in  $\text{Et}_2\text{O}$  *p*-nitrophenyldichloroacetic acid (III) was obtained in good yield. In alc. II is turned an intense  $\text{KMnO}_4$ -red by alkalies; the color gradually changes to yellow on standing and disappears on acidification but is restored by an excess of alkali.  $\text{PhCCl}_2\text{CN}$  behaves in the same way. Lifschitz and Jenner proved by spectrochem. studies that the colored salts of I are quinoid,  $\text{NaON}(\text{:O}): \text{C}_6\text{H}_4\text{:CHCN}$ , and Opolski assumed a similar structure for the colored salts of the *o*- and *m*-isomers. This seems hardly probable for the *m*-compds., as no *m*-quinones are known. II contains no H atom replaceable by a metal and can therefore neither be quinoid nor isomerize into an imide form; the question of the structure of the colored salt-like derivs of the nitrobenzyl cyanides cannot therefore as yet be considered as cleared up. II (28 g. from 30 g. I chlorinated at  $120^\circ$  in bright daylight for 11 hrs.), yellowish,  $b_D^{20}$  149.9-5°,  $d_4^{20}$  1.4465,  $n_D^{20}$  1.5710. III (5 g. from 8.5 g. II), m.  $171-2^\circ$  (slight decompn.), easily titrated with phenolphthalein in aq. alc. C. A. R.

Chlorobenzoylactic esters and their derivatives. A. WAHL AND J. ROLLAND. *Ann. chim.* [10], 10, 5-49(1928); cf. C. A. 2, 3057; 22, 1151.—By condensation of *o*-, *m*- and *p*- $\text{ClC}_6\text{H}_4\text{CO}_2\text{Me}$  with  $\text{AcOMe}$  under the influence of metallic Na, are obtained Me *o*-, *m*- and *p*-chlorobenzoylacetates (I). The *o*-I decomps. slowly at  $170-2^\circ$  and 12 mm. pressure,  $d_4^{20}$  1.027. Two mols. condense with elimination of 2 mols. of MeOH to form 6-*o*-chlorophenyl-*o*-chlorobenzoyl- $\alpha,\gamma$ -pyronone (II), m.  $216^\circ$ . *m* I,  $b_{11}$   $165-9^\circ$ ,  $d_4^{20}$  1.185, condenses in the same way, the product m.  $172^\circ$ . *p*-I, m.  $36-7^\circ$ ,  $b_{11}$   $172^\circ$ , yields a similar condensation product m.  $242^\circ$ . The isomeric I are next characterized by cryst. derivs. By the action of  $\text{PhNHNH}_2$  are prepd. *o*-, *m*- and *p*-pyrazolones (III), m., resp.,  $113-4^\circ$ ,  $144^\circ$  and  $140^\circ$ . *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{NHNH}_2$  yields pyrazolones (IV), m.  $203-4^\circ$ ,  $189^\circ$  and  $200-0.5^\circ$ .  $\text{HNO}_2$  yields Me isonitrosochlorobenzoylacetates (V), m., resp.,  $90-1^\circ$ ,  $113-4^\circ$  and  $124-5^\circ$ .  $\text{NH}_2\text{OH}\cdot\text{HCl}$  yields chlorophenylisoxazolones (V), m., resp.,  $138^\circ$ ,  $98^\circ$  and  $152^\circ$ . By the action of  $\text{PhN}_2\text{Cl}$  are prepd. Me benzeneazochlorobenzoylacetates (Va), m.  $95-6^\circ$ ,  $132-3^\circ$  and  $90-1^\circ$ , resp., *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{N}_2\text{Cl}$  gives Me *p*-nitrobenzeneazochlorobenzoylacetates, m.  $104-5^\circ$ ,  $174-5^\circ$  and  $206-7^\circ$ , resp. By condensation of Va with  $\text{PhNHNH}_2$  and of III with  $\text{PhN}_2\text{Cl}$  are obtained identical compds., 1-phenyl-3-chlorophenyl-4-phenylhydrazino-5-pyrazolones (Vb), m., resp.,  $195^\circ$ ,  $166-7^\circ$  and  $204-5^\circ$ . The I are capable of existing as enolic compds. and these tautomeric forms are demonstrated to be present at equil. to the extent of about 25%. By decompn. with dil.  $\text{H}_2\text{SO}_4$  the I are broken down into  $\text{Cl}\cdot\text{C}_6\text{H}_4\text{COMe}$ , of which the *m*-isomer has not been heretofore prepd. Derivs. of the 3 isomers are prepd. In the case of the *m*-chloroacetophenone,  $d_4^{20} = 1.2130$ , the phenylhydrazone is unstable. The chloroacetophenones are heated with  $\text{Na}_2\text{SO}_3$ , the Na sulfonate being formed in the case of the *o*- and *p*-isomers. In the case of the *m*-isomer the Cl is not replaced. Condensation of *o*-V with  $\text{BzH}$  gives benzylidene-*o*-chlorophenylisoxazolone (VI), m.  $152^\circ$ ; with *p*- $\text{Me}_2\text{NC}_6\text{H}_4\text{CHO}$ , *p*-dimethylaminobenzylidene-*o*-chlorophenylisoxazolone (VII), m.  $199^\circ$ ; with  $3,4\text{-(HO)}_2\text{C}_6\text{H}_3\text{CHO}$ , 3,4-dihydroxybenzylidene-*o*-chlorophenylisoxazolone (VIII), m.  $233-5^\circ$ . *m*-Isomers: VI, yellow, m.  $116^\circ$ ; VII, garnet, m.  $192^\circ$ ; the *m*-VIII, orange, m.  $190-2^\circ$ . *p*-Isomers: VI, yellow,

m. 154°; VII, red, m. 200°; *p*-VIII, yellow, m. 201–3°. With 3,4-(HO)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>CHO, the condensation products are capable of acting as mordant dyes. The color intensity of the *m*-Cl deriv. is greater than that of the non-chlorinated deriv.; the intensity is less with the *o*- and *p*-Cl derivs. Further, the 3 V condense with isatin chloride to yield chlorophenylisoxazole-2-indoleindigo (IX); these products are dark violet-brown crystals, m. 250°, 239° and 244° for the *o*-, *m*- and *p*-derivs., resp. W. and R. employ a previously described method (cf. C. A. 6, 2075) which consists in treating a  $\beta$ -ketonic ester in anhyd. Et<sub>2</sub>O with nitrous vapors in the presence of Ac<sub>2</sub>O. The I are thus treated and give the diketones, Me chlorobenzoylglyoxylates, ClC<sub>6</sub>H<sub>4</sub>COCOCO<sub>2</sub>Me (X), the yield being very poor due to decompn. of the X to ClC<sub>6</sub>H<sub>4</sub>CO<sub>2</sub>H. The action of Ph-NHNH<sub>2</sub> on the X varies according to the solvent and temp. By acting in cold dil. AcOH, 3 phenylhydrazones (XI) are prepd., m. 95–6°, 130° and 90–1°, resp. The point of attachment is the  $\alpha$ -ketonic group. At the same time small quantities of the Vb are obtained. These are insol. in 50% AcOH and are easy to sep. from the phenylhydrazones.

R. P. WALTON

New syntheses of coumarin derivatives. II. RICHARD WEISS AND ADALBERT KRATZ. Univ. Wien. *Monatsh.* 51, 386–96(1929); cf. Weiss and Merksammer, C. A. 23, 829. --o-C<sub>6</sub>H<sub>4</sub>(OH)<sub>2</sub>, EtOCH:C(CO<sub>2</sub>Et)<sub>2</sub> and EtONa give Et umbelliferone-3-carboxylate, m. 165–70°. 2,1,3-O<sub>2</sub>NC<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub> (9 g.), 10.8 g. AcC(:CHOEt)CO<sub>2</sub>Et and EtONa from 1.33 g. Na, warmed 20 mins. on the H<sub>2</sub>O bath, give 3-acetyl-7-hydroxy-8-nitrocoumarin, yellowish brown, m. 230–1° (decompn.). With 8 g. EtOCH:C(CO<sub>2</sub>Et)<sub>2</sub>, 5.72 g. 2,1,3-O<sub>2</sub>NC<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub> and 0.88 g. Na in EtOH, there results a tetrahydronitrodiphenyl, orange-red, darkens at 270° but does not possess a sharp m p. the alc. filtrate from the above compd. (as Na salt) yields 7-hydroxy-8-nitrocoumarin, light yellow, m. 228°; this crysts. with 0.5 mol. H<sub>2</sub>O and differs from the compd. obtained by Clayton (C. A. 4, 3076) on nitrating umbelliferone. 4,1,3-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub> and AcC(:CHOEt)CO<sub>2</sub>Et give nearly quant. 3-acetyl-6-chloro-7-hydroxycoumarin, brown, m. 241–2°; the aq. soln. has a bluish violet fluorescence; *p*-toluenesulfonyl deriv., m. 160–1°; 4,1,3-EtC<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub>, AcOH and ZnCl<sub>2</sub>, heated not over 140°, give ethylresacetophenone (I), yellowish, m. 115°, reduced by Zn and HCl to 4,6-diethylresorcinol (II), m. 65–71°. With AcC(:CHOEt)CO<sub>2</sub>Et the latter yields 3-acetyl-5-hydroxy-6,8-diethylcoumarin, brownish yellow, m. 192°; *p*-toluenesulfonyl deriv., grayish white, m. 99°; N<sub>2</sub>H<sub>4</sub>·H<sub>2</sub>O gives 2,6-dihydroxy-3,5-diethylbenzalazine, light yellow, m. 214°. With EtOCH:C(CO<sub>2</sub>Et)<sub>2</sub> II gives Et-5-hydroxy-6,8-diethylcoumarin-3-carboxylate, light yellow, m. 156°; the free acid, light yellow, m. 212°. I and EtOCH:C(CO<sub>2</sub>Et)<sub>2</sub> with EtONa give Et 5-hydroxy-6-acetyl-8-ethylcoumarin-3-carboxylate (or the 8-acetyl-6-ethyl deriv.), light yellow, softens 158°, m. 180–5°; heating with 10% EtOH-KOH for 2 hrs. gives 5-hydroxy-6(8)-acetyl-8(6)-ethylcoumarin, m. 180°. The product described in the literature as 4,6,1,3-Cl<sub>2</sub>C<sub>6</sub>H<sub>3</sub>(OH)<sub>2</sub> is probably the mono-Cl deriv., by the action of SO<sub>2</sub>Cl<sub>2</sub> there results the di-Cl deriv., m. 108–9°; with AcC(:CHOEt)CO<sub>2</sub>Et there results 3-acetyl-5-hydroxy-6,8-dichlorocoumarin, light yellow, m. 235–6° (decompn.); *p*-toluenesulfonyl deriv., m. 150–1°. C. J. WEST

The reactivity of the nitro group in 4,5-dinitroveratrole towards sodium methylate at 35° and 45°. A. H. PARVUS. Univ. Leiden. *Rec. trav. chim.* 48, 560–3(1929).—According to the investigation of Lorang (C. A. 22, 582) the introduction of the OMe group in the 5-position in 2,4-(O<sub>2</sub>N)<sub>2</sub>C<sub>6</sub>H<sub>3</sub>Cl slows down the reactivity toward NaOMe to about 1/3 of its value. The present paper deals with the influence of two OMe groups on the reactivity of a mobile nitro group. The reaction const. for the reaction between 4,5-dinitroveratrole and NaOMe in MeOH was found to be 0.0029 at 35° and 0.0088 at 45°. Taking into consideration that the reaction const. for the reaction between o-C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>2</sub> and NaOMe in MeOH are 0.0242 at 35° and 0.0695 at 45° (*Rec. trav. chim.* 18, 17(1899)), the const. published here, are to be halved according to Lorang (C. A. 22, 582; Talen, C. A. 22, 1351), it follows that the introduction of 2 OMe groups in o-C<sub>6</sub>H<sub>4</sub>(NO<sub>2</sub>)<sub>2</sub> slows down the reactivity toward NaOMe about

8 times. The following solubilities of 4,5-dinitroveratrole in abs. MeOH were detd.: at 15°, 0.0766 g.; at 25°, 0.1054 g.; at 35°, 0.1821 g. and at 45°, 0.2495 g. in 10 cc MeOH. C. F. VAN DUIN

*peri*-Dibenzyl-naphthalene and two other isomeric hydrocarbons. KAROL DZIEWONSKI AND JAN MOSZEW. *Bull. intern. acad. Polonaise* 1928, 283-91.—Three dibenzyl-naphthalenes were isolated by distn. *in vacuo* of the material left after sepg.  $\alpha$ - and  $\beta$ -C<sub>10</sub>H<sub>7</sub>CH<sub>2</sub>Ph from the condensation of PhCH<sub>2</sub>Cl with C<sub>10</sub>H<sub>8</sub> by AlCl<sub>3</sub>. I, colorless needles, m. 146.5°; II, fine needles, m. 88°; III, gleaming leaflets, m. 132°. I is obtained in best yields by condensing PhCH<sub>2</sub>Cl with  $\alpha$ -C<sub>10</sub>H<sub>7</sub>CH<sub>2</sub>Ph by AlCl<sub>3</sub>. Oxidation to 1,8-C<sub>10</sub>H<sub>6</sub>Bz<sub>2</sub> proves I to have been 1,8-dibenzyl-naphthalene. I gives with difficulty a NO<sub>2</sub> deriv., m. 141°, and can be sulfonated by ClSO<sub>3</sub>H. Both substitutions appear to be in the 4-position. II forms a picrate, orange needles, m. 107°. The constitution of II and III has not been established. C. H. PEET

The Goldschmiedt condensation products of 2,3-hydroxynaphthoic acid with aromatic aldehydes and their relation to the triphenylmethane group. MARIUS REBEK AND VINKO KRAMARŠIČ. Univ. Ljubljana. *Ber.* 62B, 477-87 (1929).—On the assumption that the color of 2,3-C<sub>10</sub>H<sub>6</sub>(OH)CO<sub>2</sub>Me (I) is due to a chromophoric group and that I can exist in equil. with a ketonic form (II), Goldschmiedt and his associates treated it with aromatic aldehydes in the presence of halogen acids and obtained condensation products of the type III (R = Ph, *p*-MeC<sub>6</sub>H<sub>4</sub>, *p*-MeOC<sub>6</sub>H<sub>4</sub>, *p*- and *m*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub> and *p*-OHCC<sub>6</sub>H<sub>4</sub>). The products crystallize well and HBr is a more effective condensing agent than HCl. Their yellow color and positive FeCl<sub>3</sub> reaction point to a keto-enol equil. similar to that of the I itself. In the compds. with R = Ph, MeC<sub>6</sub>H<sub>4</sub> and MeOC<sub>6</sub>H<sub>4</sub> the halogen is very reactive; mere heating in C<sub>6</sub>H<sub>6</sub> or Me<sub>2</sub>CO with HO compds or NH<sub>3</sub> derivs. gives the corresponding ethers or imides. On adding the reagent the light yellow soln. always deepens in color but this soon disappears. Quite evidently there are here analogies with Ph<sub>3</sub>CH derivs. The reactivity of the halogen atom in the III decreases with the substituent R in the order OMe, Me, H, *m*-NO<sub>2</sub>, *p*-CHO, *p*-NO<sub>2</sub> (the position of the CHO group in this series is uncertain). The object of the present work was to define the position of the NH<sub>2</sub> group in this series, to isolate, if possible, any intermediate products which might be formed in the replacement of the halogen, to bring the Ph<sub>3</sub>CH derivs. into the scope of the investigation and to det. if the deepening of the color during the substitution of the halogen is due to the transient formation of free radicals or colored addn. products. With *p*-Me<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>CHO and I was obtained *Me* 1-[*p*-dimethylamino- $\alpha$ -chlorobenzyl]-2-hydroxy-3-naphthoate-HCl (IV), which is exceedingly sensitive to moisture and seps. from abs. Et<sub>2</sub>O in a HCl atm. in cm.-long needles falling to a fine powder when washed with Et<sub>2</sub>O. It can not be recrystd. and must therefore be prepd. from absolutely pure materials in the purest Et<sub>2</sub>O, repeatedly washed with dry Et<sub>2</sub>O and freed from the condensing agent and solvent by passing dry air over it and letting it stand *in vacuo* over CaO and paraffin. The Cl is unusually reactive and on short standing in the air the IV becomes red and deliquesces. By cautious addn. of the reagents, oxonium and NH<sub>4</sub> salts, characterized by greater or lesser stability, were obtained. Expts. with Ph<sub>3</sub>CH derivs. along this line gave no definite results. The formation of Cl-contg. crystals was observed but analyses immediately after filtering, washing and drying gave Cl values far too low; apparently an oxonium salt is formed but it loses HCl so readily that it cannot be analyzed. Helferich and his associates describe a stable "triphenylcarbinol hydrochloride," first observed in the replacement of a H atom of glucose by the Ph<sub>3</sub>C residue and later obtained from Ph<sub>3</sub>CCl with H<sub>2</sub>O in C<sub>6</sub>H<sub>6</sub>N and from Ph<sub>3</sub>COH and HCl in C<sub>6</sub>H<sub>5</sub>N. R. and K. confirmed their results but think the product is really *triphenylpyridinium chloride*, for it is also formed from Ph<sub>3</sub>CCl and abs. C<sub>6</sub>H<sub>5</sub>N alone and also from Ph<sub>3</sub>CCl and 1 mol. C<sub>6</sub>H<sub>5</sub>N in CHCl<sub>3</sub>. It can be recrystd. unchanged from Ac<sub>2</sub>O, gives C<sub>6</sub>H<sub>5</sub>N with KOH and has the compn. C<sub>24</sub>H<sub>20</sub>NCl (found Cl, 9.69-10.56%). Attempts to isolate intermediate products in the replacement of the halogen in the III by means of org. bases were unsuccessful; only addn. products were formed and since all of these, insofar as they were isolated, were light colored, the deepening in color during the reaction cannot be ascribed to them. The halogen-free dimers (V and VI) corresponding to the III with R = Ph and *p*-O<sub>2</sub>NC<sub>6</sub>H<sub>4</sub>, which were obtained in cryst. form and in good yield, proved to be sensitive to HO-contg. solvents. In the prepn. of V with "Naturkupper C" hardly any change in color could be noted; in prepg. VI there did occur such a change but the VI itself is more deeply colored than the original III. On the other hand, with pptd., not further purified Cu or ordinary Zn dust, there was considerable deepening in color during the reaction. The cause of the bathochromism is, therefore, not the formation of either colored addn. products or free radicals.

Basic constituents seem to play a role, insofar as they favor the keto form of the compds. IV, light yellow, reddens on heating and decomps. above  $200^{\circ}$ , sol. in  $H_2O$  with ruby-red color disappearing on diln. (with deposition of white flocks), partly sol. in dil. alkalis with dirty blue color, sol. in concd.  $H_2SO_4$  with ruby-red color changed to emerald green by 1 drop of  $HNO_3$ , in  $AcOH-H_2SO_4$  with blood-red color discharged by 3-4 parts alc., insol. in but changed to a dirty red by  $SnCl_4$ , sol. in  $Me_2CO$  with reddish color, in  $CHCl_3$  without color, in  $Ac_2O$  with light ruby-red color deepening on warming and paling out on cooling, in  $PhNO_2$  with pink color changing to violet on heating and to intense green with strong fluorescence on again cooling, in  $C_6H_5N$  with light violet-red color becoming intensely violet-red on heating and pale yellow on cooling; addn. of  $H_2O$  to the fresh  $C_6H_5N$  soln. produces an ultramarine-blue color stable for some hrs.  $PhOH$  dissolves IV with red,  $MeOH$  momentarily with ruby-red color, the soln. rapidly becoming colorless and depositing crystals of the Me ether. Attempts to prep. the dye salt  $CINMe_2:C_6H_4:CHC_{10}H_5(OH)CO_2Me$  were unsuccessful; heating in  $H$  or  $CO_2$  gave non-homogeneous products. Me 1-[p-dimethylamino- $\alpha$ -hydroxybenzyl]-2-hydroxy-3-naphthoate (VII), from IV in  $Me_2CO$  with  $H_2O$  and then  $NaHCO_3$ , greenish yellow, begins to become discolored about  $140^{\circ}$ , m.  $152-4^{\circ}$ , sol. in hot dil.  $HCl$  with pink color, in concd.  $H_2SO_4$  like IV, in hot  $AcOH$  with ruby color paling on cooling, in hot  $HClO_4$  with crimson color and forming an intensely pink ppt. on cooling, in hot  $Et_2O$  without color, likewise in hot and cold  $Me_2CO$  and  $CHCl_3$ , in cold  $Ac_2O$  with light yellow color suddenly turning to crimson on boiling and again suddenly paling on cooling, in cold  $C_6H_5N$  with yellow color changing to reddish violet on boiling and to bluish and then colorless on adding  $H_2O$ , in  $PhOH$  without color change but becoming light blue on warming and pink on boiling and blue again on cooling, in  $MeOH$  without color change and turned transiently reddish by  $HCl$ ; picrate, dark yellow; *HCl salt*, from IV in  $Me_2CO$  with a few drops of  $H_2O$ , yellow, m.  $173-5^{\circ}$ , sol. in hot  $H_2O$  with red, in cold  $C_6H_5N$  with yellow color becoming crimson on heating and paling out on cooling, in  $PhOH$  with violet-red color; Me ether, from IV shaken with  $MeOH$ , then taken up in  $Me_2CO$  and treated with aq.  $NaHCO_3$ , faintly yellow, m. around  $190^{\circ}$ , shows halochromism like IV, sol. in  $PhOH$  with bluish color becoming more intense and then disappearing on warming; continued heating produces a pink color changing to blue on cooling. Methylxonium chloride,  $ClH.NMe_2C_6H_4CH(OMe.HCl)C_{10}H_5(OH)CO_2Me$ , of VII. *HCl*, from IV shaken with  $MeOH-C_6H_6$ , pearly crystals with 1 mol.  $C_6H_6$ , m. around  $82^{\circ}$  (decompn.), obtained solvent-free in yellow leaflets, m.  $155-60^{\circ}$  (decompn.), by treating IV with  $MeOH$  alone and crystg. the product from  $C_6H_6$ ; it slowly loses  $HCl$  in the air. *HCl salt* of the Me ether, from IV shaken with dry  $MeOH$  until crystal begins, then treated with  $Me_2CO$  and slowly with  $H_2O$  until the red color first produced has definitely disappeared, m.  $155-60^{\circ}$  (decompn.). Me 1-benzyl-2-hydroxy-3-naphthoate methylxonium chloride, from III ( $R = Ph$ ) with  $MeOH-CHCl_3$ , yellow, m.  $160^{\circ}$ , loses all its  $HCl$  in 3 weeks. The  $C_6H_5N$  addn. product of III ( $R = Ph$ ) has now been obtained in cryst. form (faintly yellow) from the III in  $CHCl_3$  with dry  $C_6H_5N$  and  $C_6H_6$ .  $PhNH_2$  compd., now obtained directly from III with (dild.)  $PhNH_2$  at a low temp., m.  $179^{\circ}$ . V, obtained in 70% yield when O and moisture are excluded, pale yellow, m.  $223-4^{\circ}$ .  $\alpha,\beta$ -Bis[p-nitrophenyl]bis[Me 2-hydroxy-3-naphthoate]ethane (VI), intensely orange, more labile than V, begins to m.  $185^{\circ}$ , m. completely  $195^{\circ}$ , sol. in concd.  $H_2SO_4$  with blood-red, in  $C_6H_5N$  with orange-red color.

ms Alkylanthracenes and "transannular tautomerism." V. EDWARD DE B. BARNETT AND NORMAN F. GOODWAY. Sir John Cass Tech. Inst., London. *Ber.* 62B, 423 314 (1929); cf. *C. A.* 22, 1772.—Br forms with 1,5-dichloro-9-alkylanthracenes Br derivs in which the Br atom is extraordinarily reactive; replacement of this Br atom by HO, RO or AcO gives "colorless" compds. which soon change into "yellow" fluorescent isomers which were definitely proved to have the structure I. It was suggested that the Br atom is mobile and that the Br compd. of the 9-Me deriv., e. g., is a tautomeric mixt. of II and III; the "colorless" compds. would then have the alkylidene structure II; this conception was further developed by Cook (*C. A.* 22, 587), but B. and Matthews, believing the exptl. data were not sufficient to justify a migration of groups involved in C.'s views, suggested, with reservations, an endocyclic structure, the Br compd. of the 9-benzyl deriv. being considered a tautomeric mixt. of IV and V,

and the "colorless" compds. having the structure IV. If this were true 1-chloro-9- and -10-benzylantracenes should give the same compd. IV, but an attempt by Cook to settle this point proved indecisive (*C. A.* 23, 1407), although the results favored the alkylidene rather than the endocyclic structure. The problem was then attacked by taking a compd., 1,5-dichloro-9-phenyl-9-bromoanthrone (VI), which does not contain the mobile H atom necessary for the  $IV \rightleftharpoons V$  tautomerism. VI with MeOH and EtOH and  $\text{CaCO}_3$  gave the corresponding 9-MeO- (VII) and 9-EtO derivs. (VIII), which with MeMgI yielded the dihydroanthraquinol derivs.  $\text{HOCMe}(\text{C}_6\text{H}_5\text{Cl})_2\text{CPhOR}$  (IX, R = Me, and X, R = Et). These proved to be unexpectedly stable and the corresponding alkylidene compds.,  $\text{CH}_2:\text{C}(\text{C}_6\text{H}_5\text{Cl})_2\text{CPhOR}$ , could not be isolated, but both IX and X on heating with MeOH and EtOH contg. some HCl gave greenish substances with yellow fluorescence which were beyond doubt the  $\omega$ -alkoxy derivs. XI, showing decisively the possibility of a transannular migration of alkoxy groups. Furthermore, IX heated with EtOH contg. HCl gave the same XI (R = Et) as X. In these compds. the transannular migration occurs much less readily than in the non-phenylated derivs.; with 1,5-dichloro-9-methylantracene it is generally impossible to isolate the "colorless" compd. because of the ease with which it rearranges into the "yellow" isomer, whereas, although both IX and X are converted into the "yellow" XI (R = Et) in boiling HCl-EtOH, in MeOH the change into XI (R = Me) can be effected only in sealed tubes at 100°. IX in boiling HCl-MeOH also doubtless undergoes a change but into a colorless isomer which has not yet been thoroughly studied and is probably a geometrical isomer of the *cis-trans*-type or of the kind described by Schlenk and Bergmann (*C. A.* 22, 4495). Although these results indicate that a transannular migration is possible it would be desirable to obtain decisive proof of the alkylidene structure of the colorless compds. obtained from 1,5-dichloro-9-benzylantracene. Although this has not as yet been entirely possible it has been found that both 1,5-dichloro-9-ethoxy- and -9-benzoyloxyanthrone are dealkylated by  $\text{PhCH}_2\text{MgCl}$  and the resulting oils give in AcOH with concd. aq. HCl at room temp. a *tri-Cl* compd. (XII) which must have the structure  $\text{CHCl}(\text{C}_6\text{H}_5\text{Cl})_2\text{C}(\text{CH}_2\text{Ph})\text{OH}$ , for it forms a *piperidine* compd.  $\text{C}_8\text{H}_{10}\text{NCH}(\text{C}_6\text{H}_5\text{Cl})_2\text{C}(\text{CH}_2\text{Ph})\text{OH}$  (XIII) identical with that obtained from  $\text{PhCH}_2\text{MgCl}$  and  $\text{C}_8\text{H}_{10}\text{NCH}(\text{C}_6\text{H}_5\text{Cl})_2\text{CO}$ . XIII, boiled with dil. aq. HCl, loses 1 mol.  $\text{H}_2\text{O}$  and forms a colorless compd. (XIV) to which must be assigned the alkylidene structure; it is, however, not identical with that obtained from bromo-1,5-dichloro-9-benzylantracene and is probably a geometrical isomer of the latter. As was to be expected, the *ms-Cl* atom in XII is very reactive; boiling MeOH and  $\text{CaCO}_3$  give the 10-MeO deriv. (XV) and  $\text{H}_2\text{O}$  in  $\text{Me}_2\text{CO}$  the HO deriv. (XVI), attempts to prep. the alkylidene compds. from XII, XV and XVI yielded only resinous substances. VII, m. 213°. VIII, m. 150°. 1,5-Dichloro-9-methyl-10-phenyl-9-hydroxy-10-methoxy-9,10-dihydroanthracene (IX), m. 215°, gives with boiling MeOH contg. HCl an isomer, m. 191°, sepp. from MeOH and  $\text{Me}_2\text{CO}$  with 0.5 mol. solvent. 1-EtO homolog (X), m. 205°. 1,5-Dichloro-9-methyl-10-phenyl- $\omega$ -methoxyanthracene (XI, R = Me), greenish yellow, m. 154°.  $\omega$ -EtO homolog (XI, R = Et), m. 124°. 1,5-Dichloro-9-benzoyloxyanthrone, from the 9-Br compd.,  $\text{PhCH}_2\text{OH}$  and  $\text{CaCO}_3$  on the  $\text{H}_2\text{O}$  bath, m. 157°. 1,5-Dichloro-9-methyl- $\omega$ -benzoyloxyanthracene, from the -Br deriv., yellow, m. 118°. 1,5,10-Trichloro-9-benzyl-9-hydroxy-9,10-dihydroanthracene (XII), m. 135° (vigorous decompn.) (once, from the ethoxyanthrone were obtained crystals, m. 144°, and having the compn. of a 1,5-dichloro-9-benzylidene-10-ethoxy-9,10-dihydroanthracene but which were different from the "colorless" compd., m. 190°, obtained from dichlorobromobenzylantracene and EtOH). The benzyloxyanthrone with MeMgI gave only 1,5-dichloroanthrone. XV, m. 144°. 1,5-Dichloro-9-benzyl-9,10-dihydroanthraquinol (XVI), m. 172°. 1,5-Dichloro-9-benzyl-9-hydroxy-10-piperidino-9,10-dihydroanthracene (XIII), m. 169°, seps. from MeOH and  $\text{Me}_2\text{CO}$  with 0.5 mol. solvent. 1,5-Dichloro-9-benzylidene-10-piperidino-9,10-dihydroanthracene (XIV), m. 194°.

**Action of aromatic aldehydes on phenols.** O. HINSBERG. Freiburg i. B. *Ber.* 62B, 418-21(1929).—Hitherto the reaction of aromatic aldehydes on phenols in the presence of condensing agents has been found almost without exception to give  $\text{Ph}_3\text{CH}$  derivs. by elimination of 1 mol.  $\text{H}_2\text{O}$  from 2 mols. phenol and 1 of aldehyde. By heating equiv. quantities of the phenol and aldehyde in the presence of acids ( $\text{AcOH}\cdot\text{HCl}$ ) under pressure, however, the reaction can be made to follow another course, giving what are probably 9,10-diphenyl-9,10-dihydroanthracenes. Thus, 10 g.  $\text{PhOH}$  and 12 g.  $\text{BzH}$ , heated 6 hrs. in a sealed tube on the  $\text{H}_2\text{O}$  bath in 40 cc. concd.  $\text{HCl}$  and 50 cc.  $\text{AcOH}$ , then boiled with  $\text{Ac}_2\text{O}$  and a little  $\text{Zn}$  dust, yield a product, m.  $202^\circ$ , which is probably a mixt. (I) of 2,7- and 2,6-bisacetyloxy-9,10-diphenyl-9,10-dihydroanthracene, readily sapond. by hot alc.  $\text{KOH}$  to the mixt. of 2,7- and 2,6-di-*HO* compds., darkens and sinters about  $250^\circ$ , also darkens readily on standing in the air or on recrystn. 2,7- and 2,6-Bisacetyloxy-9,10-diphenylanthracene, from I and  $\text{K}_2\text{Cr}_2\text{O}_7\cdot\text{AcOH}$ , yellow, m.  $215-35^\circ$ , converted by alc.  $\text{KOH}$  on the  $\text{H}_2\text{O}$  bath into 2,7- and 2,6-dihydroxy-9,10-diphenylanthracene hydrate,  $\text{C}_{22}\text{H}_{20}\text{O}_8$ , yellow-red cryst. powder with 1  $\text{H}_2\text{O}$ , melts with decompn. at a high temp., forms with concd.  $\text{HCl}$  a red *HCl* salt, dissolves in alkalis with the intense violet color of the benzaurins. In the same way from *p*-cresol and *p*- $\text{O}_2\text{NC}_6\text{H}_4\text{CHO}$  is obtained 1,8 (and 1,5)-dimethyl-4,5 (and 4,8)-dihydroxy-9,10-bis-*p*-nitrophenyl-9,10-dihydroanthracene, faintly yellow, m. above  $270^\circ$ . C. A. R.

**Perylene and its derivatives.** XXII. ALOIS ZINKE AND NORBERT SCHNIDER-SCHITSCH. Univ. Graz. *Monatsh.* 51, 280-4(1929); cf. C. A. 23, 2436.—Catalytic reduction of perylene ( $\text{Pd}$  on  $\text{C}$ ) gives an octahydro deriv., m.  $159-61^\circ$ , and some hexahydro deriv., m.  $189^\circ$ . 3,10-Perylenequinone gives hexahydroperylene-3,10-diol, grayish brown, m.  $298-300^\circ$ ;  $\text{H}_2\text{SO}_4$  gives a violet-red color without soln.; warming changes the color to an emerald-green, then olive and violet to a red; di-*Ac* deriv., m.  $342-3^\circ$ . 1,12-Perylenequinone gives the corresponding 1,12-diol, m. about  $260^\circ$ ;  $\text{H}_2\text{SO}_4$  gives an orange-red soln.; di-*Ac* deriv., m.  $192-4^\circ$ . 3,9-Perylenequinone did not give a homogeneous reduction product. C. J. WEST

**Polymerization of pyrrole under the influence of glycols.** A. K. PLISOV. *Ukrainskii Khim. Zhurnal* 3, Sci. Pt. 471-5(1928).—This study was undertaken to learn the relation of pyrrole (I) to ethylene hydroxide,  $\text{CH}_2\text{:CHOH}$ , and in general the interaction between I and its derivs. and  $\alpha$ -hydroxides (II) in connection with the amphoteric nature of the H in the NH group of the I. Such an interaction produced no combination between I and II, nor an isomerization of the II to aldehydes and ketones under the action of the acid character of I, as could be expected, the I having been converted to tripyrrole (III). Hitherto the polymerization of I has been successful with  $\text{HCl}$ . The heating of I with II in sealed tubes may result in formation of several reaction products, and, therefore, it was of interest to inquire whether the polymerization of I is caused by the presence of  $\text{H}_2\text{O}$ , high temp., hydroxide or products of its conversion, such as aldehydes, ketones and glycols, and it was demonstrated that on heating of I with II in the presence of  $\text{H}_2\text{O}$  there are formed glycols, which cause the polymerization of I. When 13.5 g. of I and 10 g. of II in 10 g. of  $\text{H}_2\text{O}$  are heated in a sealed tube for 10-12 hrs. in a water bath, there is obtained a reaction mass with an onion-like odor consisting of 2 layers. The upper layer is unchanged I; the lower layer was satd. with  $\text{K}_2\text{CO}_3$  whereby a new layer of dark brown color was formed, which was dried with calcined  $\text{K}_2\text{CO}_3$ . The aq.  $\text{K}_2\text{CO}_3$  soln. on distn. under reduced pressure produced a glycol, while the brown layer on fractionation under 85 mm. results in about 4 g. of I at  $102-156^\circ$ , and 7 g. of a heavy yellow liquid at  $156-185^\circ$  sol. in  $\text{H}_2\text{O}$ , alc. and  $\text{Et}_2\text{O}$ , with a strong onion-like odor, which on standing becomes rose colored and resinsified. The  $\text{HCl}$  salt is slowly formed on satn. of the base with  $\text{HCl}$  gas. In the analysis the figures obtained were between 19.5% and 20.6%, while the theory for  $\text{C}_4\text{H}_5\text{N}$  requires 20.8%. The product has all the properties of III; on heating with an alc. lamp there is liberated  $\text{NH}_3$ , and on heating to  $310-20^\circ$  some  $\text{NH}_3$  and an oily substance are formed, which with steam gives I and crystals of indole, m.  $52^\circ$ . When 5 g. of I and 5 g. of ethylene hydroxide  $\text{CH}_2\text{:CHOH}$  are heated in a sealed tube for 20 hrs. in a water bath, the I remains unchanged, and no aldehyde is formed, consequently the  $\text{CH}_2\text{:CHOH}$  is not capable of isomerization to an aldehyde in the presence of I, while I does not polymerize under the influence of the  $\text{CH}_2\text{:CHOH}$ . The heating of I with  $\text{H}_2\text{O}$  at various temps. up to  $150^\circ$  in sealed tubes caused no change of I. The product obtained by heating 7 g. of I with 5 g. of glycol dried with calcined  $\text{K}_2\text{CO}_3$  and twice distd. in a sealed tube for 6-8 hrs. in a water bath, gave on fractionation the same III as was previously prepd. by heating  $\text{CH}_2\text{:CHOH}$  with I in presence of  $\text{H}_2\text{O}$ . Consequently  $(\text{CH}_2\text{OH})_2$  is capable of polymerizing I to III, and, therefore, on heating aq.  $\text{CH}_2\text{:CHOH}$  with I, the polymerization of I is caused by the glycol formed from the

$\text{CH}_2\text{:CHOH}$ . When 10 g. of  $\text{CMe}_2\text{:CMeOH}$  with 10–11 g. of I and 10 cc. of  $\text{H}_2\text{O}$  are heated in a sealed tube for 10–12 hrs. in a water bath, and the reaction mass is treated as described above, there is formed only a very small amt. of III. The inferior polymerizing influence of  $\text{CMe}_2\text{:CMeOH}$  as compared with that of  $\text{CH}_2\text{:CHOH}$  is possibly due to less mobility of H of the OH group and the resulting minor ability of forming glycols, i. e., the properties of the H of  $(\text{CH}_2\text{OH})_2$  are nearer to those of the acid character, and consequently its polymerizing action will be greater. CHAS. BLANC

**Polymerization of pyrrole.** A. K. PLISOV. *Ukrainskii Khim. Zhur.* 3, Sci. Pt., 477–80 (1928).—It is known that pyrrole (I) is changed by HCl to red pyrrole (II), with the empirical formula  $\text{C}_{12}\text{H}_{14}\text{N}_2\text{O}$ . The poor soly. of II presents difficulties in detg. its structure. The elementary compn. reveals that under the action of acids the process of polymerization of pyrrole nuclei is accompanied by oxidation. The 1st intermediate product of this process is tripyrrole (III). There is some difference in the properties and the structure of III obtained by different workers. Denshtedt's III is an oily, crystallizable liquid, to which he ascribes the formula IV

Chelintzev obtained III as a cryst. substance rapidly changeable in the air, the freshly prepd. product having a low N content and also a mol. wt. of 264 instead of the theoretical of 210, which on standing for 2 days is changed to 311. He proposed the following formulas, V and VI, which, however, are now incompatible with his later findings

$\text{CH:CH.N} \text{---} \text{CH-}$        $\text{-N.CH:CH.}$  Denshtedt obtained III by treating I

with 20% HCl, neutralizing with  $\text{NH}_3$  and extg. with  $\text{Et}_2\text{O}$ . Chelintzev prepd. III either in abs.  $\text{Et}_2\text{O}$  or with better results in abs.  $\text{C}_6\text{H}_6$ . When 13.5 g. of I in 350 cc. of  $\text{C}_6\text{H}_6$  was treated with gaseous HCl and the III was set free with  $\text{NH}_3$ , there were formed 2 forms of III, one cryst. and the other amorphous. P.'s studies of the action of di-, tri- and polybasic alcs. on I revealed that it is capable of polymerisation on heating with liquid alcs. The I when heated 6–8 hrs. on the water bath with a small quantity of  $(\text{CH}_2\text{OH})_2$  undergoes a partial polymerization (preceeding abstr.), a reaction which proceeds more readily with glycerol. When 5 g. of glycerol freed from acid impurities by distn. and 8 g. of I are heated to boiling for 30 mins., there is observed the presence of a condensation product of I. If I is polymerized only by the acid properties of the alcs., then the more rapid action with glycerol than with  $(\text{CH}_2\text{OH})_2$  is explained by the more acid character of the former. The heating of I with solid alcs., such as mannitol and erythritol, produces no changes. AcH evidently combines with I on heating in a sealed tube as the entire mass is converted into a dark brown, gum-like substance sol. only in concd. AcOH with red color. Perhaps this substance is a product of polymerization. No polymerization was obtained by heating I with glucose; however, a probable product of combination of the two, which, after crystn. from pyridine, m.  $190^\circ$ , was isolated. CHAS. BLANC

**The secondary valence forces of indole nitrogen.** O. SCHMITZ-DUMONT and E. MORZKUS. Univ. Bonn. *Ber.* 62B, 466–73 (1929).—In continuation of the study of the additive power of pyrrole N (*C. A.* 23, 2968) the additive power of some derivs. of indole (I) has been investigated, chiefly with  $\text{SnCl}_4$  and  $\text{SnBr}_4$ , and also in some cases with  $\text{TiCl}_4$  and  $\text{AlBr}_3$ . I itself behaves entirely differently from pyrrole with  $\text{SnCl}_4$ , giving the normal compd.  $\text{SnCl}_4 \cdot 2\text{I}$ , from which it can be recovered almost completely. The product has a blue-green color. In the reaction there is first formed a yellow ppt. which, however, soon assumes the blue-green color. The same results were obtained in the most varied solvents and at temps. as low as  $-60^\circ$ . The color, nevertheless, is due to the formation of an intensely blue by-product. The formation of this stable  $\text{SnCl}_4$  product is evidence of the greater additive power of the indole as compared with that of the pyrrole N, but it is not yet sufficient to form stable products with the more weakly additive  $\text{SnBr}_4$ . With  $\text{TiCl}_4$  and  $\text{AlBr}_3$ , however, I forms the normal compds.  $\text{TiCl}_4 \cdot 2\text{I}$  and  $\text{AlBr}_3 \cdot \text{I}$ , from both of which it can be recovered unchanged. While the  $\text{AlBr}_3$  compd. is an almost white cryst. powder, the  $\text{TiCl}_4$  deriv. is deep violet.

It is improbable that the color can be explained in the same way as that of the  $\text{SnCl}_4$  compd., nor can it be due to reduction to tervalent Ti, for aq. alkalis at once form white  $\text{Ti}(\text{OH})_3$ . Polymerization greatly increases the additive power of the indole as well as of the pyrrole N. Triindole (II) forms the compds.  $\text{SnCl}_4 \cdot 2\text{II}$ ,  $\text{SnBr}_4 \cdot 2\text{II}$ ,  $\text{TiCl}_4 \cdot 2\text{II}$  and  $\text{AlBr}_3 \cdot 2\text{II}$ , and, under certain conditions,  $\text{SnCl}_4 \cdot 2\text{II}$ , the Al compd. being colorless, the Sn derivs. faintly yellow and the Ti compd. deep violet-black. Substitution of the imido H atom by Me does not increase the additive power of the N but rather decreases it; under the same conditions as with I, *N*-methylindole (III) forms with  $\text{SnCl}_4$  no normal addn. product from which it can be recovered.  $\text{AlBr}_3$  does, however, form the normal compd.  $\text{AlBr}_3 \cdot \text{III}$ .  $\alpha$ -Methylindole (IV), surprisingly, does not form a normal product with  $\text{SnCl}_4$  but yields the compds.  $\text{C}_9\text{H}_7\text{NSnCl}_3$  and  $\text{SnCl}_3\text{H} \cdot 2\text{IV}$ . The former with aq.  $\text{NH}_3$  at once regenerates pure IV and hence there is no doubt that the imido H atom is substituted by Sn, while the latter gives up all its Sn to  $\text{C}_9\text{H}_7\text{N}$  as  $\text{SnCl}_4 \cdot 2\text{C}_9\text{H}_7\text{N}$ , showing that it is a pure addn. compd. The reaction may be represented as follows:  $\text{IV} + \text{SnCl}_4 = \text{C}_9\text{H}_7\text{NSnCl}_3 + \text{HCl}$ ;  $\text{IV} + \text{HCl} = \text{IV} \cdot \text{HCl}$ ;  $\text{IV} \cdot \text{HCl} + \text{IV} + \text{SnCl}_4 = \text{IV} \cdot \text{SnCl}_3\text{H} \cdot \text{IV}$ . Bis-[ $\alpha$ -methylindyl]methene (V) reacts like dipyrromethene with  $\text{SnCl}_4$ , giving the compd.  $\text{SnCl}_4 \cdot \text{V}$ , although the two N atoms in V are different; no compd. with  $\text{SnBr}_4$  could be obtained. Bis-[ $\alpha$ -methylindyl]dimethylmethane treated in  $\text{CHCl}_3$  with  $\text{SnCl}_4$  and freed *in vacuo* of the  $\text{CHCl}_3$  and excess of  $\text{SnCl}_4$  yielded an orange product contg. the components in the ratio 1:1, but which did not regenerate the original methane; attempts to isolate the addn. product by immediate pptn. with ligroin gave chiefly the unchanged methane.  $\text{SnCl}_4 \cdot 2\text{I}$ , begins to soften  $133^\circ$ , m.  $153^\circ$  (decompn.).  $\text{AlBr}_3 \cdot \text{I}$ , begins to m.  $130^\circ$ , m. completely  $140^\circ$ .  $\text{SnCl}_4 \cdot \text{II}$ , m.  $166-8^\circ$ .  $\text{SnCl}_4 \cdot 2\text{II}$ , softens  $130^\circ$ , m. around  $150^\circ$ .  $\text{SnBr}_4 \cdot 2\text{II}$ , m.  $120-33^\circ$  (decompn.).  $\text{C}_9\text{H}_7\text{NSnCl}_3$ , m.  $149^\circ$ .  $\text{SnCl}_3\text{H} \cdot 2\text{IV}$ , m.  $207^\circ$ .  $\text{SnCl}_4 \cdot \text{V}$ , m.  $201^\circ$ , orange-red. C. A. R.

*N*-Arylisatins and isomeric acridine-meso-carboxylic acids. JOSEPH MARTINET AND ANDRÉ DANSETTE. *Bull. soc. chim.* 45, 101-9 (1929).—The synthesis of 1-phenyl-4,5-benzoisatin (*N*-phenyl- $\beta$ -naphthosatin) (I) by condensation of  $\beta$ - $\text{C}_{10}\text{H}_7\text{NHPH}$  (II), m.  $108^\circ$ , and Et mesoxalate followed by alkaline sapon., decarboxylation and air oxidation showed that this reaction could be carried to I or to benzacridine-meso-carboxylic acid (III) at will. The initial condensation goes readily by heating II with  $\text{CO}(\text{CO}_2\text{Et})_2$  at  $180^\circ$  for 20 mins. or by boiling their soln. in AcOH, forming the Et 1-phenylbenzo-4,5-dioxindole-3-carboxylate (IV), m.  $171^\circ$ ; Ac deriv., m.  $177^\circ$ . 1-Phenylbenzo-4,5-dioxindole (V), microscopic, felted needles, m.  $95-102^\circ$ ; Ac deriv., m.  $150^\circ$ , was obtained by sapon. of IV in absence of air followed by acidification and by reduction of I by  $\text{Na}_2\text{S}_2\text{O}_4$ . Oxidation of V by air in alk. medium or alk. sapon. of IV in presence of air readily gave I, red needles, m.  $227^\circ$ . The Na salt of phenylamino-2-naphthyl-1-glyoxylic acid (VI) first results and this is immediately converted into I on acidification. I forms a characteristic phenylhydrazone, orange, m.  $195^\circ$ . The Ba, Cu and Pb salts of I are unstable. The K salt with 3 mols.  $\text{H}_2\text{O}$  of crystn. is more stable. VI left in alkalis too long (especially hot) is transformed into benzo-1,2-acridine-9-carboxylic acid (VII). VII is prepd. by boiling IV with 10% KOH and it forms many stable metallic salts. VII heated with soda-lime yielded benzoacridine (also called naphthacridine and  $\beta$ -chrysidine), m.  $126-31^\circ$ . C. H. PEET

Separation of carbazole from crude anthracene. B. V. MAKOROV. *J. Chem. Ind. (Moscow)* 6, 41-5 (1929).—Numerous expts. were made to verify the methods of the Ger. patents 393,693 and 386,597. The conclusions are: The HCHO method gives satisfactory results, provided anthracene is preliminarily freed from phenanthrene and other impurities by washing with xylene. The anthracene obtained is not completely N-free, in spite of the numerous treatments with HCHO. A single treatment with a mixt. of 150 parts EtOH, 15 parts 40% HCHO and 3 parts  $\text{Na}_2\text{CO}_3$  per 50 parts crude anthracene contg. 20% carbazole is not sufficient, 2-3 such treatments are required; moreover, larger quantities of HCHO must be used when operating with anthracenes rich in carbazole. When the HCHO mixt. contains an excess of  $\text{Na}_2\text{CO}_3$ , and the heating is prolonged, the results are bad. Anthracenes previously treated by KOH cannot be freed from N compds. by the HCHO method. The treatment of anthracenes by KOH should be carried out without access of air and at as low a temp. and for as short a time as possible. Instead of repeatedly treating anthracene by the HCHO mixt., the former can be extd. by the HCHO mixt. in a Soxhlet apparatus, in which case EtOH may be replaced by its 30-40% aqueous soln., whereas caustic and carbonated alkalis can be replaced by lime. Each expt. is described in detail. BERNARD NELSON

Carbazole derivatives. I. F. KEHRMANN AND FRIEDRICH ZWEIFEL. *Helv.*

*Chim. Acta* 11, 1213-9(1928).—From the nitro derivs. of carbazole by reduction, acylation, and substitution numerous compds. of technical significance have been produced. This report deals with 3-nitrocarbazole (I), where the nitro group is *p*- to the ring N. I was prepd. by methods reported earlier. By alc.  $\text{SnCl}_4$  and  $\text{HCl}$ , I was reduced and treatment with  $\text{Ac}_2\text{O}$  gave, from alc., colorless crystals of 3-acetamidocarbazole (II), m. 217°. II with 5 times its wt. of  $\text{Ac}_2\text{O}$  and  $\text{ZnCl}_2$  yielded, on addn. of  $\text{H}_2\text{O}$ , a yellow-white mixt. of di- (III) triacetyl-3-aminocarbazole (IV). This mixt. was warmed with  $\text{HOAc}$  and nitrated with a mixt. of equal parts of  $\text{HNO}_3$  and  $\text{HOAc}$ . The soln. slowly deposited greenish yellow prismatic crystals of the almost pure  $\alpha$ -nitrodiacetyl-3-aminocarbazole (V), m. 226°. The  $\beta$ -isomer (VI) was not isolatable by fractional crystn., but with elimination of one of the Ac groups, the 2 resulting isomeric forms were separable. By not too long warming with concd. alc.  $\text{NaOH}$  V lost only the Ac group attached to the ring N and  $\alpha$ -nitro-3-acetamidocarbazole (VII) was formed, bright red needles, m. 274°. Warming VII with sufficient 1:1 alc.  $\text{H}_2\text{SO}_4$  to produce soln. gave a cryst., yellow-brown sulfate (VIII), which, with  $\text{NH}_3$ , gave from alc. dark violet needles, m. 233°, of  $\alpha$ -nitro-3-aminocarbazole (IX).  $\alpha$ -o-Diaminocarbazole (X) resulted as the Sn double salt by warming IX with  $\text{HCl}$ ,  $\text{SnCl}_4$ , and Sn until soln. took place, and could be isolated by ether extn. of its alk. soln. as colorless crystals which decompd. on heating and quickly oxidized in air. Without isolating X its Sn-free soln. gave with benzil in alc. on gentle warming at 100° the  $\alpha$ -quinoxaline deriv. (XI), citron-yellow, m. 273°. XI was isolated by making alk. with  $\text{NH}_3$  the concd. alc. soln. of the  $\text{HCl}$  salt and adding  $\text{H}_2\text{O}$  drop by drop. The mixt. of III and IV was rubbed with alc.  $\text{NaOH}$  until the yellow particles were replaced by a red cryst. meal. VII was sepd. by filtration from the soln. of  $\beta$ -nitro-3-acetamidocarbazole (XII) and that of IX. By pptn. with  $\text{H}_2\text{O}$  and crystn. from alc., XII was obtained as red-brown needles, m. 198°. By hydrolysis with alc.  $\text{H}_2\text{SO}_4$  XII gave  $\beta$ -nitro-3-aminocarbazole (XIII), dark red-brown, m. 177°. Exactly as IX gave X so XIII gave  $\beta$ -o-diaminocarbazole (XIV), colorless, insol. in  $\text{H}_2\text{O}$ , and readily oxidized in the air. XIV gave with benzil a bright yellow quinoxaline deriv. (XV), m. 261°. XV differs from XI in yielding a cryst. orange-red perchlorate (XVI) by the direct action of  $\text{HClO}_4$  on the soln. in which condensation has taken place, and in readily giving a green-blue color, changing to violet, with concd.  $\text{H}_2\text{SO}_4$  as a water-sol. sulfonic acid is formed, whereas XI is only slowly altered with  $\text{H}_2\text{SO}_4$ . The location of the second N-contg. group in the substituted phenyl is at 2 or 4, but as yet in which series, the  $\alpha$  or the  $\beta$ , it is at 2, and in which at 4 has not been detd.

G. ALBERT HILL

Three isomeric 1-tolyl-3,5-dimethyl-1,2,4-triazoles and several of their salts. FRANZ HERNLER. Univ. Innsbruck. *Monatsh.* 51, 267-76(1929).—Mol. quantities of *o*- $\text{MeC}_6\text{H}_4\text{NHNH}_2$ ,  $\text{HCl}$ ,  $\text{Ac}_2\text{NH}$  and  $\text{AcONa}$  give 48% of 1-*o*-tolyl-3,5-dimethyl-1,2,4-triazole (I), m. 24.5°, solidifies 28.25°;  $\text{HCl}$  salt, m. 214-6°; picrate, yellow, m. 192-3°; chloroplatinate, yellow, m. 158-62°; mercurichloride, m. 136-7°. The *m*-isomer corresponding to I (58% yield),  $b_{11}$  147-9°;  $\text{HCl}$  salt, m. 206-7°; picrate, yellow, m. 138-9.5°; chloroplatinate, crystg. with 2  $\text{H}_2\text{O}$ , m. 220-3°; mercurichloride, m. 181°; mercurichloride- $\text{HCl}$ , m. 215-20°. The *p*-isomer corresponding to I (30% yield),  $b_{11}$  151-5°, m. 47-9°;  $\text{HCl}$  salt, m. 233-5°; picrate, yellow, m. 128-9°; chloroplatinate, reddish brown, m. 223-5° (decompn.); mercurichloride,  $\text{C}_{11}\text{H}_{13}\text{N}_3$ ,  $\text{HgCl}_2$ , from an acid soln., m. 150-2°; from  $\text{H}_2\text{O}$  there ppts. the compd.  $(\text{C}_{11}\text{H}_{13}\text{N}_3)_4 \cdot 3\text{HgCl}_2$ , m. 144-7°.

C. J. WEST

Plant pigments. P. KARRER. *Bull. soc. chim.* 43, 1041-58(1928); cf. following abstr.—Plant pigments may be classed as those localized in the cell, and called lipochromes, and those in the cell juice, such as flavones, flavonols and anthocyanins. The latter are pyrylium salts, derived from phloroglucinol and a *p*-hydroxybenzene. In some the hydroxyls are methylated, as is shown by alk. decompn., but the 4'-OH group is always free. This is involved in the blue pigments which are quinoid compds. whereas the red ones are oxonium salts. Blue flowers yield a higher ash than the red, since the former are alkali or alk.-earth salts. Some pigments yield on hydrolysis an acid, e. g., *p*- $\text{HOC}_6\text{H}_4\text{CH}:\text{CHCO}_2\text{H}$ ; by the prepn. of methylated pigment derivs. this group is shown to be attached to a phloroglucinol hydroxyl but the particular one is not known. Thus a close relation exists between the depsides and this group of pigments. That the sugar in the anthocyanins is attached as a glucoside on carbon 3, at least in some cases, K. established by a study of hydrolyzed methylation products, with those prepd. synthetically. This conclusion was strengthened by a study of the oxidation products with  $\text{H}_2\text{O}_2$ . Three crocetins may be isolated from saffron, the  $\alpha$ - and  $\beta$ -forms are glucosides, the  $\gamma$ - a di-Me ester of the  $\alpha$ -form. Reduction to a satd. compd. shows the 16-C chain to contain 7 double bonds, which are presumably conjug-

gated, and crocetin is an aliphatic, dibasic acid, with 3 methyls on the chain at carbons 4, 8 and 12. The relationship of this substance to isoprene is apparent. G. A. H.

**Plant pigments. IX (?) Crocetin and lycopin.** P. KARRER, A. HELFENSTEIN AND ROSE WIDNER. *Helv. Chim. Acta* 11, 1201-9(1928); cf. preceding abstr.—The saffron pigment,  $\alpha$ -crocetin (I), is reduced by  $\text{TiCl}_3$  in  $\text{NaOH}$  to  $\alpha$ -dihydrocrocetin,  $\text{C}_{19}\text{H}_{24}\text{O}_4$  (II), light S-yellow, m. 192-3°. By a large excess of  $\text{TiCl}_3$ , up to 40 mols. to 1, a thick honey-colored oil, *hexahydro- $\alpha$ -crocetin*,  $\text{C}_{19}\text{H}_{28}\text{O}_4$  (III) results. I with concd.  $\text{H}_2\text{SO}_4$  gives a violet-blue color, II wine-red, while III becomes brown-red. A table of color effects with different acids and salts on I, II and III is included. II, unlike I, readily adds  $\text{O}_2$  from the air until a wt. increase of 21% has occurred. The nature of the oxidized material, C 56.37%, H 6.46%, has not been established. III is much more stable than II. I is probably 4,8,12-trimethylhexadeca[2,4,5,8,10,12,14-heptane]dioic and II is 4,8,12-trimethylhexadeca[3,5,7,9,11,13-hexaene]dioic acid.  $\gamma$  Crocetin, earlier reported, has now been shown to m. 199-200° when pure. The presence of  $\text{CO}_2\text{H}$  groups favors reduction with  $\text{TiCl}_3$ ; lycopin (IV),  $\text{C}_{40}\text{H}_{58}$ , is not reduced under conditions which reduce I. Perhydrolycopin (V), previously reported, is  $\text{C}_{40}\text{H}_{58}$ , as mol. wt. detns. in  $\text{C}_6\text{H}_6$  and *p*- $\text{BrC}_6\text{H}_4\text{Me}$  indicate,  $d_4^{25}$  0.8211,  $n_D^{25}$  1.45837. The mol. refraction, 187.13, indicates that V is aliphatic. By converting dihydrophytol into its corresponding bromide,  $\text{C}_{30}\text{H}_{41}\text{Br}$ , 1-bromo-3,7,11,15-tetramethylhexadecane, b. 185-188°, is obtained. When this is treated with Na and K, 2 hydrocarbons result. One seems to be phytene,  $\text{C}_{20}\text{H}_{34}$ , b. 127°; the other  $\text{C}_{40}\text{H}_{58}$ , b. 240-2°, is 2,6,10-, 14,19,23,27,31-octamethyldotriacontane, and seems to be identical with V. G. A. H.

**The nitration of  $\alpha$ -2-pyridyl- $\beta$ -ethylurea.** R. P. DIKSHOORN. Univ. Leiden. *Rec. trav. chim.* 48, 545-7(1929).—In view of the difficult nitration of the pyridine nucleus (cf. Friedl, C. A. 6, 1294; *Monatsh.* 34, 760(1913)) it was to be expected that the nitration of  $\alpha$ -2-pyridyl- $\beta$ -ethylurea would give rise to the formation of  $\alpha$ , $\alpha$ -2-pyridylnitro- $\beta$ , $\beta$ -ethylnitrourea or  $\alpha$ -2-pyridyl- $\beta$ , $\beta$ -ethylnitrourea. It is now shown that the latter compd. is formed. On heating 2 g.  $\alpha$ -aminopyridine, 20 cc. dry ether and 15 cc.  $\text{EtNCO}$  in a sealed tube at 100° for 2 hrs.,  $\alpha$ -2-pyridyl- $\beta$ -ethylurea, m. 119°, is obtained on cooling. On nitrating this substance, either with abs.  $\text{HNO}_3$  alone at -10° or with a mixt. of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  at -20°, a clear soln. is obtained on pouring the reaction mass into water. From this soln.  $\text{EtNHNO}_2$  may be extd. with ether, whereas, after neutralization to congo red, picric acid gives a yellow ppt. of  $\alpha$ -aminopyridine picrate, m. 223-5°; the latter base itself, m. 56°, may be obtained by making the soln. alk., distg. with steam and extg. the distillate with ether. From the fact that  $\alpha$ -aminopyridine itself is nitrated to pyridylnitramine, it follows that the urea deriv. broke down only when the mixt. was poured into water. C. F. VAN DUIN

**Derivatives of 8-aminoquinoline.** R. P. DIKSHOORN. Univ. Leiden. *Rec. trav. chim.* 48, 517-44(1929); cf. C. A. 23, 1903.—The direct nitration of aminoquinolines not being possible (Kaufmann and Zeller, C. A. 12, 1390), the amino group has been protected by coupling 8-aminoquinoline with  $\text{EtNCO}$  and the  $\alpha$ -8-quinolyl- $\beta$ -ethylurea, so obtained, has been nitrated. The reactions of the nitration products with water, ales and  $\text{NH}_3$  were then studied as well as the nitration of 8-quinolylurea and quinoline-8-carbamic acid (cf. Knipphorst, C. A. 20, 589; Lorang, C. A. 22, 230). On heating 14 g. 8-aminoquinoline, 30 cc. ether and 8 cc.  $\text{EtNCO}$  in a sealed tube during 1 hr. at 100°,  $\alpha$ -8-quinolyl- $\beta$ -ethylurea (I) is obtained in 95% yield; it exists in 2 monotropic modifications, m. 176° and 181°, the latter form being obtained by crystn. from benzene and on melting the other form and allowing it to resolidify. When 1 g. of I is nitrated with 8 cc. abs.  $\text{HNO}_3$  at -15°,  $\alpha$ -5-nitro-8-quinolyl- $\beta$ , $\beta$ -ethylnitrourea (II), m. 143-5°, is obtained; it does not give the nitramine reactions of Franchimont and Bamberger and of Liebermann, but, on heating with concd.  $\text{H}_2\text{SO}_4$ , splits off  $\text{HNO}_3$  (Thiele and Lachmann reaction). Contrary to the usual behavior of nitroureas, II is fairly stable toward boiling water, but on subjecting the *not recrystd.*, freshly prepd., nitration product to this treatment, 5-nitro-8-aminoquinoline (III), m. 197°, and 5-nitroquinoline-8-carbamic acid (IV), m. < 300°, were obtained. The structure of III was proved by diazotation in 60%  $\text{H}_2\text{SO}_4$  and boiling the diazonium compd. with alc., 5-nitroquinoline, m. 69-71°, being formed. On boiling II with a large amount of  $\text{MeOH}$  or  $\text{EtOH}$ , *Me 5-nitroquinoline-8-carbamate*, m. 210°, and the *Et ester*, occurring in 2 modifications, m. 111.5° and 121°, are obtained. With either aq. or alc.  $\text{NH}_3$ , II yields 5-nitro-8-quinolylurea, yellow, m. 245°. When I is nitrated by adding to 1 g. in 8 cc. abs.  $\text{HNO}_3$ , 8 cc. concd.  $\text{H}_2\text{SO}_4$  drop by drop and keeping at room temp. for 24 hrs., 5,7-dinitroquinoline-8-carbamic acid (V), m. 230°, was formed; from the mother liquor the Ba salt of  $\text{EtNHNO}_2$  was isolated, the  $\alpha$ -5,7-dinitroquinolyl- $\beta$ , $\beta$ -ethylnitrourea, which is formed in the nitration, having reacted, on pouring out the reaction liquid into water,

with the formation of V and  $\text{EtNHNO}_2$ . On boiling with  $\text{EtOH}$ , V passes into *Et* 5,7-dinitroquinoline-8-carbamate, m.  $195^\circ$ , while, on heating V in 50%  $\text{H}_2\text{SO}_4$  (by vol.) at  $100^\circ$  for an hr., 5,7-dinitro-8-aminoquinoline, m.  $188^\circ$ , is obtained. The interaction of Me and Et chloroformate, 8-aminoquinoline and  $\text{K}_2\text{CO}_3$  in boiling ether leads to the formation of *Me* quinoline-8-carbamate (VI), m.  $45^\circ$ , and the *Et* ester (VII), m.  $66^\circ$ . Nitration of VI and VII with abs.  $\text{HNO}_3$  alone gives the 5-nitro derivs., m.  $210^\circ$  and  $114-5^\circ$ , already described above, further nitration of these mononitro derivs. with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  yielding the 5,7-dinitro derivs., m.  $190^\circ$  for the Me compd. and  $166-7^\circ$  for the Et compd. (above the m. p.  $195^\circ$  was given by D. for the Et ester; see below). When concd. aq. solns. of 8-aminoquinoline-HCl and KCNO are mixed, a mixt. of 8-quinolyurea (VIII), m.  $223-4^\circ$ , and 8-quinolybiuret, m.  $250-2^\circ$ , is formed, which could be sepd. into its components by means of boiling water, in which VIII dissolves. If, however, the prepn. is carried out in 50%  $\text{AcOH}$  at a low temp., VIII is practically the sole product. The nitration of VIII with abs.  $\text{HNO}_3$  alone, gives rise mostly to the formation of a mixt. or an additive compd. of  $\alpha$ -5-nitro-8-quinolyl- $\beta$ -nitrourea, decomp.  $190^\circ$ , and VIII, while under special circumstances, for which the original paper is to be consulted, the dinitro compd. may be obtained as the chief product, together with a small amount of a substance of unknown structure, m.  $285^\circ$ . With boiling water, MeOH and EtOH,  $\alpha$ -5-nitro-8-quinolyl- $\beta$ -nitrourea is converted into 5-nitro-8-aminoquinoline, m.  $195-6^\circ$ , Me and Et 5-nitroquinoline-8-carbamate, m.  $209-10^\circ$  and  $114-5^\circ$ , resp., already described above. The structure of IV was proved by the action of water, MeOH and EtOH, 5-nitro-8-aminoquinoline, m.  $193-5^\circ$ , the Me and Et esters being formed; the latter being obtained in the modification m.  $121^\circ$ . With boiling MeOH and EtOH, V was converted into the corresponding esters, the Me ester, m.  $205^\circ$ , whereas the nitration of Me 5-nitroquinoline-8-carbamate gave the same ester, m.  $190^\circ$ . The Et ester, prepd. by esterification, m.  $195^\circ$ , and the nitration product of Et 5-nitroquinoline-8-carbamate m.  $167^\circ$ . The structural identity of both these pairs of esters was established by the conversion into 5,7-dinitro-8-aminoquinoline by means of  $\text{NH}_3$  and the higher-melting products could be converted into the lower-melting ones by heating with alc. HCl in a sealed tube at  $100^\circ$ . Attention is drawn to the great stability of these mono- and dinitroquinolinecarbamic acids, which D. ascribes to a betaine-like structure, formed by means of the tertiary N atom. When 8-aminoquinoline and its 5-nitro- and 5,7-dinitro deriv. are diazotized in 60%  $\text{H}_2\text{SO}_4$  and the diazonium solns., thus obtained, are poured into water, ppts. are obtained, which do not show the typical diazonium reactions and which are considered by D. to consist of the so called *anti*-diazohydrates. The relatively great stability of these compds. probably is due to the formation of an internal salt with the tertiary N atom of the pyridine ring. The following compds. are described: quinoline 8-*anti*-diazohydrate (IX), decomp.  $145^\circ$ ; 5-nitroquinoline 8-*anti*-diazohydrate (X), decomp. violently  $185^\circ$  and being easily reconverted into the reactive *syn*-diao form under the influence of acids. Its soln. in 60%  $\text{H}_2\text{SO}_4$  couples with  $\beta$ -naphthol and its soln. in 48% HBr yields 5-nitro-8-bromoquinoline on treatment with  $\text{CuBr}$ ; 5,7-dinitroquinoline 8-*anti*-diazohydrate (XI) decomp. violently with ignition at  $155^\circ$ ; neither this compd. nor its soln. in concd.  $\text{H}_2\text{SO}_4$  gives the normal reactions of diazonium compounds.

 X: R = H; R' =  $\text{NO}_2$   
 XI: R and R' =  $\text{NO}_2$

C. F. VAN DUIN

**Halodinitroquinolines.** R. P. DIKSHOORN. Univ. Leiden. *Rec. trav. chim.* 48, 550-9 (1929).—Attempts to prep. halodinitroquinolines are not to be found in the literature; in the present paper such attempts are described together with the prepn. of halomononitroquinolines. 5-Bromoquinoline was prepd. from 5-aminoquinoline (cf. C. A. 23, 1903) by the Sandmeyer reaction (cf. Freydl, *Monatsh.* 8, 582 (1887)); it appeared necessary to carry out the diazotization in strongly acid soln., otherwise dyestuff and resin formation occurred. The compd. m.  $48^\circ$ , even after purification *via* the oxalate (cf. *J. prakt. Chem.* [2], 40, 385 (1889; 73, 250 (1906))). On nitration with abs.  $\text{HNO}_3$  alone or with a mixt. of  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$ , 5-bromoquinoline gives a mixt. of the 6- and 8-nitro compd.; the latter seps. on pouring the reaction product into water while the 6-nitro compd. may be obtained on neutralization of the filtrate with

$\text{NH}_3$ . From 10 g. 5-bromoquinoline, 12 g. 5-bromo-8-nitroquinoline, m.  $146^\circ$ , and 1 g. 5-bromo-6-nitroquinoline, m.  $126^\circ$ , were obtained. The further nitration of 5-bromo-8-nitroquinoline with  $\text{HNO}_3$  and  $\text{H}_2\text{SO}_4$  at  $100^\circ$  during 20–40 hrs. does not yield a dinitro deriv.; the substance is oxidized in this way with the formation of a dibromonitroquinoline and quinolic acid; the di-Br compd. was isolated on pouring the liquid on ice and probably consists of 3,5-dibromo-8-nitroquinoline, m.  $195^\circ$ , quinoline being brominated by preference in the pyridine nucleus. The quinolic acid was obtained as the Cu salt,  $\text{C}_7\text{H}_5\text{O}_4\text{NCu} \cdot 2\text{H}_2\text{O}$ , from the mother liquors. 8-Bromoquinoline, also prep'd. from 8-aminoquinoline by the Sandmeyer reaction,  $b_{760}$   $305\text{--}10^\circ$  (slight decompn.);  $b_{18}$   $165\text{--}6^\circ$ . On nitration the sole product isolated was 5-nitro-8-bromoquinoline, m.  $136\text{--}7^\circ$  (cf. *J. prakt. Chem.* [2], **48**, 153(1893)), the constitution of which was proved by its prep'n. from 5-nitro-8-aminoquinoline by the Sandmeyer reaction. On boiling 1 g. 5-nitro-8-bromoquinoline in 10 cc.  $\text{HNO}_3$  and 10 cc. concd.  $\text{H}_2\text{SO}_4$ , neither nitration nor oxidation takes place, the mononitro compd. being recovered unchanged. A halodinitroquinoline, however, could be prep'd. by means of the Ullmann-Nadai reaction (*Ber.* **41**, 1870(1908)) as follows: 10 g. 8-hydroxyquinoline (Kallbaum) in 25 cc. warm AcOH was added slowly to 100 cc. 60%  $\text{HNO}_3$ , cooled in ice; when the flask was taken out of the cooling bath, a vigorous oxidation soon took place, the temp. rising to  $50^\circ$ . On pouring the nitration mixt. into 2 l. of water, 10 g. 5,7-dinitro-8-hydroxyquinoline, m.  $325^\circ$ , was obtained. On heating 5 g. of the dinitro compd. with 6 g.  $\text{PhNEt}_2$  and 4 g.  $p\text{-McC}_6\text{H}_4\text{SO}_2\text{Cl}$  for 6 hrs. at  $100^\circ$ , 8-chloro-5,7-dinitroquinoline, m.  $154^\circ$ , was formed. C. F. VAN DUIN

Quinolyl-2,4-dinitronaphthylamines. R. P. DIKSHOORN. Univ. Leiden. *Rec. trav. chim.* **48**, 548–9(1929).—Several condensation products of org. bases with chloro-(bromo)-2,4-dinitrobenzene have been prep'd. for the identification of amines (cf. *Rev. trav. chim.* **2**, 31, 103(1883)) by heating alc. solns. of the reacting compds. When, however, the same procedure was adopted for 5- and 8-aminoquinolines (Meigen, *C. A.* **2**, 2558) it was found that 5-aminoquinoline did not react with 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{Cl}$  under the usual conditions, the reaction taking place only when the 2 substances were fused together. It was now found that although 2,4-dinitrochloronaphthalene is 20 times as reactive as the benzene deriv. (Talen, *C. A.* **22**, 1351), its behavior toward both the aminoquinolines is the same as that of 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{Cl}$ , the 5-amino compd. reacting only when the 2 constituents were fused together. On heating 1.2 g. 5-aminoquinoline and 1.0 g. chloro-2,4-dinitronaphthalene, mixed intimately, for 2 hrs. at  $100^\circ$ , 5-quinolyl-2,4-dinitronaphthylamine, m.  $195^\circ$ , was obtained. The interaction of 8-aminoquinoline with chloro-2,4-dinitronaphthalene in alc. at  $100^\circ$  for 6 hrs. yields 8-quinolyl-2,4-dinitronaphthylamine, m.  $196^\circ$ . For identification purposes with aminoquinolines,  $\text{C}_{10}\text{H}_8\text{Cl}(\text{NO}_2)_2$  thus offers no advantages over 2,4-( $\text{O}_2\text{N}$ ) $_2\text{C}_6\text{H}_3\text{Cl}$ . C. F. VAN DUIN

Acridine. III. Hydrogenation of acridine with sodium amalgam. KURT LEHMSTEDT and HEINRICH HUNDEKMARK. Tech Hochschule Hannover. *Ber.* **62B**, 414–8 (1929); cf. *C. A.* **23**, 144. —Graebe and Caro found that acridine in alc. with Na-Hg gives dihydroacridine (acridan),  $\text{C}_{13}\text{H}_{11}\text{N}$  (I), and an "insol. hydroacridine" (II). I has been studied by many investigators but not much was known of II. G. and C. in the analysis of a prep'n. still contg. Hg obtained a C:H ratio of 13:11.6 and concluded that it was formed by further reduction of I. L. and H. have now found, however, that II contains O and has the compn.  $\text{C}_{13}\text{H}_{10}\text{ON}_2$ . It is quite unstable and on dry distn. or short heating with concd.  $\text{H}_2\text{SO}_4$  decomp. into 1 mol. each of acridine, I and  $\text{H}_2\text{O}$ ; Graebe's statement that only acridine is formed with  $\text{H}_2\text{SO}_4$  is correct only to a certain extent, for it is only after long heating that the  $\text{H}_2\text{SO}_4$  oxidizes the I to acridine. The ease with which II splits into two O-free acridine mols. indicates that the O is not bound to C but is in an ether-like combination with the N, and the 9,10,9',10'-tetrahydro-10,10'-diacridyl 10,10'-oxide structure seems to accord best with the properties and method of formation of II. II dissolves in boiling  $\text{C}_6\text{H}_6\text{N}$  but from the soln. there sep. prisms (III), m.  $220^\circ$ , having the compn.  $\text{C}_{26}\text{H}_{20}\text{N}_2$ ; they have no basic properties, decomp. on fusion into equal parts of acridine and I but are not split into 2 parts by concd.  $\text{H}_2\text{SO}_4$ ; they give, instead, a new base which has not yet been thoroughly studied. From its whole behavior, III must be *ms*-9,10,9',10'-tetrahydro-10,10'-diacridyl. I has a great tendency to form addn. compds.: I.  $\text{AgNO}_3$ , white ppt., soon darkening with sepn. of Ag; I.  $\text{HgCl}_2$ , yellow ppt. dehydrogenated on heating by the bivalent Hg; 2l.  $\text{NaOEt}$ , m.  $170^\circ$ , deposits pure I when dissolved in boiling alc. and cooled. With 1 mol. acridine-HCl in alc., I forms a deep green soln. (violet by transmitted light, changing to brown on heating and back to violet on cooling); evapn. gives green-black prisms, I.  $\text{C}_{13}\text{H}_9\text{N} \cdot \text{HCl} \cdot 1.5\text{H}_2\text{O}$ . The green soln. is decolorized

by  $\text{H}_2\text{O}$  or  $\text{Et}_2\text{O}$ , which ppt. I and  $\text{C}_{13}\text{H}_9\text{N} \cdot \text{HCl}$ , resp. A dark green soln. is also obtained from I and acridine in glacial  $\text{AcOH}$ . C. A. R.

**Strychnos alkaloids. XLVIII. Cleavage of the oxime of brucinonic acid with alkali.** HERMANN LEUCHS. Univ. Berlin. *Ber.* 62B, 407-9 (1929); cf. C. A. 23, 1387.—Whereas brucinolic acid,  $\text{C}_{22}\text{H}_{26}\text{O}_8\text{N}_2$ , is smoothly decompd. by 1.25 mols. alkali at  $20^\circ$  or by  $\text{NH}_4\text{-MeOH}$  at  $100^\circ$  into isomeric brucinolones and  $\text{HOCH}_2\text{CO}_2\text{H}$ , the corresponding ketonic acid, brucinonic acid,  $\text{C}_{22}\text{H}_{24}\text{O}_8\text{N}_2$  (I), is attacked only with difficulty; more than 60% is recovered unchanged, at least 10% is changed into a hydrate and cleavage is to be detected only by the formation of a little  $\text{HOCH}_2\text{CO}_2\text{H}$  and of an amorphous product. Removal of a  $\text{CO}_2\text{H}$  group and of another C atom from acids of the I series can be effected by the Curtius degradation through the azides but the products contain 1 mol. more of  $\text{H}_2\text{O}$  than the products obtained by alkali cleavage, and as brucinolic acid does not undergo the Curtius degradation it was not possible to compare the products obtained from the 2 acids. It was therefore attempted to effect the cleavage with alkali of some deriv. of I, and it was found that when the oxime (II) of I is allowed to stand 12 days at  $15^\circ$  with 2.5 mols. *N* NaOH, although about 50% is still recovered unchanged, it nevertheless yields about 30% of neutral or slightly acid products, about  $\frac{2}{3}$  of which can be isolated in cryst. form, chiefly yellowish prisms (III), m.  $295\text{--}300^\circ$ , having the expected compn.  $\text{C}_{21}\text{H}_{21}\text{O}_8\text{N}$ , and an isomer, m.  $250\text{--}8^\circ$ . Dehydrobrucinolone (III) is insol. in *N*  $\text{NaHCO}_3$  but sol. in  $\text{NH}_4\text{OH}$  and *N* alkali; its acetate turns brown around  $225^\circ$ , sinters and foams about  $240^\circ$ , slowly dissolves in *N* alkali with sapon. C. A. R.

**3-Methoxy-4-ethoxyphenylaminoethane.** K. SAWAI. *J. Pharm. Soc. Japan* 49, 260-3 (1929).—The study of 2 alkaloids, *corybulbine* and *isocorybulbine* was previously reported by Späth and Dobrowsky (C. A. 19, 2959). S. quite independently undertook the study on the position of the OH radical of the above alkaloids. Vanillin (40 g.) and KOH (12.2 g.) at  $65\text{--}70^\circ$  on addn. of  $\text{EtHSO}_4$  (50 cc.) gave *vanillin Et ether* (I), m.  $65^\circ$ . Condensation of I with  $\text{MeNO}_2$  gave *3-methoxy-4-ethoxy- $\alpha$ -nitrostyrene* (II), m.  $15^\circ$ . Catalytic reduction of II with Pt black gave *3-methoxy-4-ethoxyphenylaminoethane* (III), m.  $194\text{--}5^\circ$ . The HCl salt of III (1 g.) with  $\text{ClC}_2\text{H}_5$  (1 g.) in KOH gave *6-methoxy-7-ethoxy-1-keto-1,2,3,4-tetrahydroisoquinoline* (IV), m.  $195\text{--}6^\circ$ . IV agrees with S. and D.'s oxidation product of *isocorybulbine*. F. I. NAKAMURA

**Glucoside of Rosa multiflora.** I. H. KONDO, K. IWAMOTO AND Y. KUCHIHA. *J. Pharm. Soc. Japan* 49, 232-8 (1929).—The authors extd. from *Rosa Multiflora* a glucoside, multiflorin (I),  $\text{C}_{27}\text{H}_{36}\text{O}_{16}$ , m.  $147\text{--}70^\circ$ . Hydrolysis of I gave an aglucone (II) and sugar. II, multiflorinetin,  $\text{C}_{16}\text{H}_{10}\text{O}_6$ , m.  $283\text{--}96^\circ$ , is optically inactive and shows flavanone reactions. Acetylation of II gave 2 compds.:  $\text{C}_{16}\text{H}_8\text{O}_7\text{Ac}$ , m.  $196^\circ$ , and  $\text{C}_{16}\text{H}_8\text{O}_6\text{Ac}$ , m.  $181\text{--}3^\circ$ . Methylation of II with  $\text{Me}_2\text{SO}$  gave  $\text{C}_{16}\text{H}_8\text{O}_5(\text{OMe})_2$ , m.  $153^\circ$ . KOH fusion of II gave phloroglucinol (m.  $207^\circ$ ) and *p*- $\text{HOC}_6\text{H}_4\text{CO}_2\text{H}$ , m.  $213^\circ$ . The tests for sugar gave positive furfural, Rosenthaler and also osazone reactions. It is certain that I is a glucoside and II is 1,3,4'-trihydroxyflavanol. F. I. N.

**The formula of Digitalinum verum.** A. WINDAUS AND E. HAACK. Univ. Göttingen. *Ber.* 62B, 475-6 (1929).—The formula derived for Digitalinum verum from its cleavage products is  $\text{C}_{36}\text{H}_{56}\text{O}_{14}$  but the glucoside forms no well-defined crystals and has no sharp m. p., so that it is difficult to judge of its purity and analyses of different preps. do not agree well; 59.97-61.07% has been found for the C content while the calcd. value is 60.6%. It seemed desirable, therefore, to study carefully a well-crystd. deriv.; such a compd. is the Ac deriv., which was prepd. by Kiliani's method. It seps. from  $\text{Ac}_2\text{O}$  in flat needles, sinters slightly  $166^\circ$ , m.  $212\text{--}3^\circ$  (if plunged into a bath at  $160^\circ$  and heated rapidly, it m.  $175\text{--}6^\circ$ , resolidifies and again m.  $212\text{--}4^\circ$ ),  $[\alpha]_D^{20} -17.4^\circ$ ,  $-18.1^\circ$  ( $\text{CHCl}_3$ , *c* 4.415, 1.01, resp.),  $[\alpha]_D^{16} -16.9^\circ$  ( $\text{CHCl}_3$ , *c* 2.43), C 59.77, 59.73% H 7.26, 7.14%; calcd. for  $\text{C}_{36}\text{H}_{56}\text{O}_{14}\text{Ac}$ , 59.72, 7.11%, resp. This formula is also confirmed by the Ac content as detd. both by the Freudenberg method and by sapon. C. A. R.

**Humic acid.** G. I. STADNIKOV AND P. KORSHEV. *Kolloid-Z.* 47, 136-41 (1929).—Humic acid obtained from Merck's "acidum huminum" has been estd. by pptn. with  $\text{Ba(OH)}_2$ . Pptn. proceeds slowly to completion. The result does not depend on the concn. of the  $\text{Ba(OH)}_2$ . The reaction is like the adsorption of this hydroxide to stearic acid but unlike the reaction of humic acid with sugar. This would mean it acts strictly as an acid in this case. The resulting equiv. of 147 is not in agreement with that obtained by Oden of 320-340 because adsorption is partly due here to phenol HO groups. The effect of alkali salt concn. on the color of Ba humate was then studied. The salts used were  $\text{KNO}_3$ ,  $\text{KCl}$ ,  $\text{NaNO}_3$ , and  $\text{NaCl}$ . The concn. of sol. humate formed

is proportional to the concn. of alkali salt while that of the Ba salt changes in a complicated manner since its concn. increases much faster than that of the sol. humate. This is expressed by several chem. equations.

Organic oxygen compounds. SOC. CHIM. DE LA GRANDE-PAROISSE, AZOTE ET PRODUITS CHIM. Fr. 651,167, Aug. 24, 1927. Alcs., aldehydes, ketones, acids, esters and other org. O compds. are produced by the action of  $CO$ , or gases contg. it, on water in the liquid or gaseous state in the presence of mixed catalysts contg. at least one of the series: K, Na, Mg, V, Cr, Mo, Fe, Co, Ni, Cu, Ag, Zn, Cd, Hg, As, Sb, Bi, assocd. with at least one of the series: Be, Mg, Al, Ce, Si, Ti, Zr, Th, U, Li, Ca, Sr, Ba, W. In examples, mixed carbonates of Mn, Mg and Al are reduced at  $300^\circ$  with  $CO$ , and a mixt. of  $CO$  and  $H_2O$  is passed through at  $450^\circ$ , the excess of water contains 5-6% of various alcs. A soln. of  $ThO_2$  and  $K_2CO_3$  in  $HCOOH$  is dried on pumice stone, a current of  $CO$  at  $250^\circ$  and 500 atm. is passed over it and finally a mixt. of  $CO$  and  $H_2O$ , a soln. of  $HCOOH$  is obtained. Sol. and insol. esters are obtained when  $CuCO_3$ ,  $ThO_2$  and  $Bi_2O_3$  are used, a soln. of alc. when  $MnO_2$ , Al and Mg or  $Pb(NO_3)_2$  and  $Sr(NO_3)_2$  are used, alcs. and other compds. when  $Sb_2O_3$  and  $Th(NO_3)_4$  are used, fatty acids and alcs. when  $Th(NO_3)_4$  and  $Co(NO_3)_2$  are used.

Dehydrating organic substances. ALBERT VERLEY. Fr. 650,539, Mar. 7, 1928. Liquids are dehydrated at low temp. by heating gently with constant stirring and absorbing the vapors as they are formed in conc.  $H_2SO_4$ , the acid being cooled during the operation, and then concd. in an appropriate app. as it becomes hydrated. An app. is described.

Separating hydrocarbon mixtures. I. G. FARBENIND. A.-G. Fr. 650,972, Mar. 17, 1928. Unsatd. hydrocarbons of low b. p. are sepd. from one another or from other substances of low b. p. by fractional distn. under pressure, the vapors being directed from the bottom to the top of a distg. column and being withdrawn as vapor at one or more points in the upper part of the column. Liquids having higher b. ps. may be added to the liquids. If the b. ps. of the constituents are very close, substances which lower the vapor tension of one or more of the constituents may be added. Unsatd.

hydrocarbons may be extd. from mixts. with other hydrocarbons by treatment with org. solvents free from hydrocarbons, and removing the solvent by heat. Several examples are given.

**Purifying alcohols** such as isopropyl alcohol derived from unsaturated hydrocarbons. HYUN E. BUC (to Standard Oil Development Co.). U. S. 1,712,475, May 7. Products such as those comprising mainly iso-Pr alc. and which are derived from unsatd. hydrocarbons are agitated with a colorless petroleum oil having a b. p. above 260°, the oil is sepd. and the process repeated with fresh quantities of oil, and the alc. is subsequently distd.

**Ether-alcohols.** I. G. FARBENIND. A.-G. Fr. 650,973, Mar. 17, 1928. Mixed polyvalent ether-alc. are obtained by reacting alkylene oxides, their derivs. or transformation products with polyatomic alc. contg. more than 2 C atoms, or their derivs. not contg. O groups other than the OH groups. In examples, sorbitol is heated in an autoclave to 140° for 12 hrs. with ethylene oxide, giving a very viscous liquid. Pentaerythritol is similarly treated in the presence of boric anhydride at 125°, giving a sirupy liquid. Gelatin is heated to 30–40° in water and the ether-alc. from sorbitol is added. Glass plates are dipped in the liquid, withdrawn and dried, thin transparent sheets are obtained which may be used for wrapping chocolate, etc. Glycols, glucose and saccharose may also be used.

**Carbohydrate ethers.** LEON LILIENFELD. Ger. 475,214, Aug. 26, 1919. See Brit. 149,320 (C. A. 15, 436).

**Alkali metal alcoholates.** LUCAS P. KYRIDES (to National Aniline & Chemical Co.). U. S. 1,712,830, May 14. A soln. formed of caustic alkali such as NaOH and denatured EtOH or other alc. contg. 2 or more C atoms is subjected to fractional distn. in the presence of a sufficient quantity of a liquid such as C<sub>6</sub>H<sub>6</sub> which forms a min b. p. azeotropic mixt. including all the water, so that the azeotropic mixt. is distd. off and a soln. of the alkali metal alcoholate remains in the still.

**Polymerizing dienes.** THOMAS MIDGLEY, JR., CARROLL A. HOCHWALT and CHARLES A. THOMAS (to General Motors Corp.). U. S. 1,713,236, May 14. Dienes such as isoprene in relatively pure condition are subjected to the action of a metal catalyst comprising an alloy of alkali metals which is liquid under the working conditions under which polymerization is effected; *e. g.*, an alloy of Na and K, m. —12°.

**Highly chlorinated perylenes.** ALOIS ZINKE and KONRAD FUNKE (to Felice Bensa). U. S. 1,713,362, May 14; Fr. 651,658, Mar. 23, 1928. Hepta- to dodecachloroperylenes are formed by mixing an inert liquid solvent such as PhNO<sub>2</sub> with a chloroperylene contg. not more than 6 atoms of Cl and an inorg. chloride such as AlCl<sub>3</sub> adapted to serve as a Cl-transferring agent and then passing a current of dry gaseous Cl through the mixt. Cf. C. A. 22, 3667.

**Hydroxyalkylamines.** I. G. FARBENIND. A.-G. Fr. 650,574, Mar. 8, 1928. Hydroxyalkylamines are produced by slowly adding alkylene oxides to NH<sub>3</sub> or its substitution products. Thus, 2600 parts of ethylene oxide is added slowly to 3870 parts of 25% aq. NH<sub>3</sub> at 25–30°, giving 90–95% triethanolamine. If 352 parts of ethylene oxide is added to 3400 parts of 25% aq. NH<sub>3</sub> at 10°, monoethanolamine is obtained.

**Aminoanthraquinones.** W. SMITH, J. THOMAS AND SCOTTISH DYES, LTD. Brit. 299,333, April 19, 1927. Halogen atoms in the 1-position are removed from halogenated aminoanthraquinones by use of alk. reducing agents and the leuco compd. formed is subsequently oxidized. The reduction may be effected with metals, hydrosulites and glucose, in solns. of hydroxides of alkali or alk. earth metals, and the products may be purified by recrystn. from an org. solvent or by pptn. from their solns. in H<sub>2</sub>SO<sub>4</sub>. Several examples are given.

**Hydrogenating polyhydroxy compounds.** I. G. FARBENIND. A.-G. Brit. 299,373, Oct. 24, 1927. Comps. such as sugars, starch, cellulose, glycerol, glucosans, glyconic acid and cyclic polyhydroxy compds. are hydrogenated by treatment with activated H under high pressure (usually 70–100 atm., but possibly ranging from 10 to 1000 atm.) and at temps. of above 150° (preferably 190–300°). Glycerol and its further reduction product, 1,2-dihydroxypropane, may form the main products. Hydrogenating catalysts are used such as those of the Fe and Pt groups, Cu, Ag, Au or tungstic acid, which may be mixed with each other and used on a carrier.

**Liquid hydrocarbons from acetylene.** J. YLLA-CONTE. Brit. 299,425, Oct. 26, 1927. Structural details are specified of an app. for producing C<sub>6</sub>H<sub>6</sub> and other light liquid hydrocarbons by condensation of C<sub>2</sub>H<sub>2</sub> by heating the latter in an iron or steel vessel to the temp. of reaction and circulating the gas through a refrigerating app. outside the vessel to sep. condensable products and then injecting the uncondensed

gas into the reaction vessel again to prevent undue rise of temp. and to mix the gases. A fan and an annular conduit open at both ends and spaced within the reaction vessel serve to effect circulation of the gases within the vessel.

**Anthraquinone derivatives.** I. G. FARBININD. A.-G. (Paul Nawiasky, Fritz Helwert and Arthur Krause, inventors). Ger. 470,503, Jan. 28, 1927. Addn. to 469,135 (C. A. 23, 1284). Those products obtained in the prior patent which do not contain oxidizable substituents, are purified by after treatment with an oxidizing agent. In the examples, the derivs. obtained in the prior patent are treated with hypochlorite soln. or  $K_2MnO_8$ .

**Thiourea derivatives.** SILESIA VEREIN CHEM. FAB. (Hans Klein and Walter Flemming, inventors). Ger. 475,477, Dec. 5, 1926. Aromatic disubstituted thioureas are prep'd. by the reaction:  $Na_2CS_3 + 2RNO + H_2O = SC(NHR)_2 + Na_2S_2O_3$ , R being an aromatic radical. The prepn. of *p,p'*-dihydroxydiphenylthiourea from nitrosophenol, and of tetramethyldiaminodiphenylthiourea, m. 184–185°, from *p*-nitrosodimethylaniline are described by way of example. Cf. C. A. 22, 4133.

**Chlorine derivatives.** I. G. FARBININD. A.-G. Fr. 650,732, Mar. 10, 1928. Cl derivs. of 1,3-dimethylbenzene-4-sulfonic acid (I) are prep'd. by treating this acid in soln. in a mineral acid with Cl or chlorinating agents, preferably with the addn. of a catalyst. The sulfonic group may be split off by hydrolyzing agents, or may be replaced by Cl if the latter is used in excess. In examples, NaOCl is introduced into a soln. of I in water heated to 40°. The product is the Na salt of 2-chloro-1,3-dimethylbenzene-4-sulfonic acid, the Pb salt of which is difficultly sol. and the Ba salt is almost insol. in water, the amide m. about 223°. The same acid is obtained if Cl is introduced into a soln. of I in conc.  $H_2SO_4$  preferably using I as a catalyst. If the Na salt of this acid is dissolved in dild.  $H_2SO_4$  heated to 160–170°, and superheated steam is passed through, 2-chloro-1,3-dimethylbenzene, m. 185–7°, distills. Examples are (1) dichloro-1,3-dimethylbenzene-4-sulfonic acid (Ber. 23, 2320) using  $FeCl_3$  as catalyst, and by hydrolysis 2,6-dichloro-1,3-dimethylbenzene, which formerly was not obtained free from its isomers, (2) the Na salt of trichloro-1,3-dimethylbenzene-4-sulfonic acid (the amide m. above 325°) and by hydrolysis 2,5,6-trichloro-1,3-dimethylbenzene, m. 95–96°, b. 255–260°, and (3) tetrachloro-1,3-dimethylbenzene, m. 218–220°. Cf. C. A. 22, 2756.

**N-hydroxyethyl derivatives of aminohydroxybenzenes.** GUSTAV REDDELIEN and WERNER MUELLER (to Agfa Ansco Corp.). U. S. 1,712,716, May 14. *N*-Hydroxyethyl derivs. of aminohydroxybenzenes corresponding to the general formula  $HOC_6H_4NXCH_2CH_2OH$ , wherein X represents H or the group  $\cdot CH_2CH_2OH$ , are made by condensing a highly active deriv. of ethane contg. one atom of O and contg. in their mol. the atom figuration  $-CH_2CH_2O-$  comprising halohydrin of glycol and ethylene oxide at ordinary or raised temp. with an aminohydroxybenzene; in some cases an acid-binding agent should be present and there may also be used a diluent, a solvent, or a catalyst. The products form colorless crystals, easily sol. in water, acids, alkalies alc., acetone, and EtOAc and form with  $H_2SO_4$  colorless salts which may be recrystd. from alc. as colorless prisms easily sol. in water. 4-[Bis(hydroxyethyl)amino]-1-hydroxybenzene, m. 140°; 4-(hydroxyethyl)amino-1-hydroxybenzene, m. 96–7°; 2-[bis(hydroxyethyl)amino]-1-hydroxybenzene, when not purified is a brownish oil and when purified forms colorless laminated crystals which decompose above 240°; 2-(hydroxyethyl)amino-1-hydroxybenzene m. 80–1°. Various details of procedure for making these compds are given. Cf. C. A. 22, 4540.

**Esters of amino propanes.** WALTER SCHOELLER and HERBERT SCHOTTE (to Chemische Fabrik auf Actien (vorm. E. Schering)). U. S. 1,711,696, May 7. Pharmaceutical products are prep'd. which correspond to the formula  $XOCH_2CH(OY)CHR'R''$ , in which X is an acyl group, Y an alkyl, R' a H atom or an alkyl or aryl, R'' a H atom or alkyl, R''' a H atom or alkyl, or R' and R''' together a cyclic radical, and in which the 2 remaining affinities of the N can be satisfied by the addition of an alkyl halide. These esters form colorless or nearly colorless salts sol. in water and alc. and are well adapted in the form of their salts for therapeutic use. They may be formed by the esterification of hydroxyaminopropanes which have already been preliminarily etherified in the  $\beta$ -position. Allyl alc. is treated at ordinary temp. in a soln. of MeOH with  $Hg(OAc)_2$ . After 30 mins. the solvent is removed by evapn. and after dilg. with water the residue neutralized with  $NaHCO_3$ . An aq. soln. of KBr is added in excess and an oil seps., which, on being triturated with some EtOAc, crystallizes. After drying in the air, the compd.,  $CH_3(OH)CH(OMe)CH_2HgBr$ , is boiled in aq. suspension or better in a soln. of EtOAc with one mol. I during about 20 mins., until decolorization ensues, whereupon the Hg salt is removed and the residue is subjected

to distn. The  $\alpha$ -hydroxy- $\beta$ -methoxy- $\gamma$ -iodopropane,  $b_{0.4}$  65–6°, is heated with an equal weight of  $\text{Et}_3\text{NH}$  during 2 hrs. to 100°. The liquid which on cooling partly solidifies is taken up with an equal quantity of water. On the addn. of  $\text{K}_2\text{CO}_3$  the  $\alpha$ -hydroxy- $\beta$ -methoxy- $\gamma$ -diethylaminopropane is sepd. in the form of an oil which  $b_{1.3}$  62–3°, has the strong smell and reaction of a base and readily dissolves in ether. *p*-Nitrobenzoate-HCl crystd. from  $\text{C}_6\text{H}_6$  or  $\text{AmOH}$ , m. 143–4°; *p*-aminobenzoate-HCl, m. 159°, sol. in  $\text{H}_2\text{O}$ , and is a vigorous anesthetic. The following compds. may be similarly prepd. (all m. ps. uncor.):  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}_2\text{NMe}_3\text{I}$ , (I) needles, m. 108–9°, sol. in  $\text{H}_2\text{O}$ ;  $\text{CH}_2(\text{OH})\text{CH}(\text{OEt})\text{CH}_2\text{I}$ , colorless oil,  $b_{1.2}$  78–80°, decompd. by light or air, insol. in  $\text{H}_2\text{O}$ ;  $\text{CH}_2(\text{OH})\text{CH}(\text{OEt})\text{CH}_2\text{NEt}_3$ , colorless liquid,  $b_{12}$  100–1°, basic properties, sol. in  $\text{H}_2\text{O}$  and  $\text{Et}_2\text{O}$  (*p*-nitrobenzoate-HCl, m. 152° sol. in  $\text{H}_2\text{O}$ ; *p*-aminobenzoate-HCl, m. 152°, sol. in  $\text{H}_2\text{O}$  and alc., anesthetic);  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}_2\text{NH}_2$ , thick oil,  $b_{10}$  104–5°;  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}_2\text{NHMe}$ , oil,  $b_{12}$  about 75°;  $\text{CH}_2(\text{OH})\text{CH}(\text{OEt})\text{CH}_2\text{NHMe}$ , oil,  $b_{13}$  89–91°; (with piperidine)  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}_2\text{NC}_4\text{H}_9$ , colorless oil,  $b_{0.3}$  81–2°, sol.  $\text{H}_2\text{O}$ ,  $\text{Et}_2\text{O}$  and alc., basic properties (*p*-nitrobenzoate-HCl, m. 163–4°, sol. in  $\text{H}_2\text{O}$  and alc., difficulty sol. in  $\text{EtOAc}$ ; *p*-aminobenzoate, m. 169–70°, sol. in  $\text{H}_2\text{O}$ , difficulty sol. in  $\text{EtOAc}$  and  $\text{Me}_2\text{CO}$ , anesthetic);  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}(\text{HgBr})\text{Ph}$ , crystd. from  $\text{CHCl}_3$ , m. 110–1°;  $\text{CH}_2(\text{OH})\text{CH}(\text{OEt})\text{CH}(\text{HgCl})\text{Ph}$ , m. about 86°, sol. in  $\text{MeOH}$ ,  $\text{EtOH}$ ,  $\text{EtOAc}$  and hot  $\text{C}_6\text{H}_6$ , difficulty sol. in petroleum ether;  $\text{CH}_2(\text{OH})\text{CH}(\text{OMe})\text{CH}(\text{NEt}_3)\text{Ph}$ , slightly colored oil, b. 123–5° in high vacuum, difficulty sol. in  $\text{H}_2\text{O}$ . The following esters of I have the property of causing peristaltic movements of the intestines: acetate, crystd. from pyridine and  $\text{AcOH}$ , m. 161–2°, sol.  $\text{H}_2\text{O}$ , alc. and dilute acids; monoester of ethylphosphoric acid, thick slightly brownish sirup,  $\text{Ba}(\text{OH})_2$  gives Ba salt slightly sol. in  $\text{H}_2\text{O}$ ; acid sulfate, thick sirup, sol. in  $\text{H}_2\text{O}$ .

**Amino and nitrodiaryl sulfides; dyes; etc.** BRITISH DYESTUFFS CORP., LTD., and M. MENDOZA. Brit. 299,501, July 27, 1927. Aminodiaryl sulfides of the general type formula  $\text{C}_6\text{H}_5\text{COOH}(1)\text{OH}(2)\text{SAr}(3)$  substituted in the 5-position or carrying a benzo group in positions 5,6 in which Ar represents an aromatic residue contg. at least one  $\text{NH}_2$  group, are obtained by reduction of the products of condensation of the corresponding 1-thiol-2-hydroxy-3-carboxylic acid with an aromatic nitro compd. carrying labile H. As starting materials there may be used 3-thiol-5-methyl(or chloro)-salicylic acid and 1-thiol-2,3-hydroxynaphthoic acid and 1,2- and 1,4-chloronitrobenzenes. The 3-thiol-5-methylsalicylic acid is made by treating 3-chlorosulfonyl-5-methylsalicylic acid or the corresponding sulfonic acid with Zn dust and reducing the resulting 5,5'-dimethyl-3,3'-dithiobisalicylic acid (suitably by alk. hydrosulfite). 3-Thiol-5-chlorosalicylic acid and 1-thiol-2,3-hydroxynaphthoic acid are made in a similar manner from the corresponding chlorosulfonyl compds. or sulfonic acids. The aminodiaryl sulfides prepd. as described are used as components in the *manuf. of azo dyes* which, due to the sepn. of a chelate group from a chromophoric group by the sulfide bridge, remain unchanged in color by after-chroming. The monoamino sulfides may be diazotized and coupled with usual components and the diamino sulfides may be treated with  $\text{HNO}_2$  to produce dyes of the Bismark brown type, or may be used as second components, or may be monoacylated and used as first components, or in some instances may be tetrazotized and coupled with components. Several examples of production of dyes by these methods are given.

**Arsinic acids.** MILLE GERMAINE C. L. A. J. BARNIER. Fr. 651,178, Aug. 25, 1927. Arsine oxides are oxidized to arsinic acids either by air or by  $\text{H}_2\text{O}_2$  in the presence of catalysts. In examples, *p*-dimethylaminophenylarsine oxide is dissolved in water, a soln. of  $\text{Mn}(\text{OAc})_2$  is added and a current of air passed through the soln. for 8 hrs. or  $\text{H}_2\text{O}_2$  is added, giving *p*-dimethylaminophenylarsinic acid.

**Benzoic acid.** HERBERT W. DAUDT (to E. I. Du Pont de Nemours & Co.). U S 1,712,753, May 14. A soln. of a metal acid phthalate is heated at a temp. between 150° and 300° (suitably about 200–220°) in the presence of heavy metal salts such as  $\text{CuSO}_4$  or other Cu or Hg salt capable of forming phthalates and capable of splitting off  $\text{CO}_2$  from phthalic acid.

**Acetic acid.** SOC. ANON. DES DISTILLERIES DES DEUX-SÈVRES. Fr. 651,528, Sept. 10, 1927. See Brit. 296,974 (C. A. 23, 2449).

**Acetic anhydride and other anhydrides.** BRITISH CELANESE, LTD., H. DREYFUS and W. BADER. Brit. 299,342, July 23, 1927. In producing the corresponding anhydride, a liquid aliphatic acid such as  $\text{HOAc}$  or its salt such as  $\text{NaOAc}$  is treated with a phosphoric acid of a lower degree of hydration than  $\text{H}_3\text{PO}_4$  or with an alkali or alk. earth salt of such acid, e. g., Na metaphosphate, with or without use of pressure or of a diluent, at temps. of 100–250°.

**Chloroacetic anhydride, etc.** CHARLES J. STROSACKER and CLARENCE C. SCHWEG-

IER (to Dow Chemical Co.). U. S. 1,713,104, May 14. An acid chloride such as chloroacetyl chloride is heated with monochloroacetic acid or other suitable org. carboxylic acid, in the presence of a suitable metal chloride such as  $\text{AlCl}_3$  in order to form the corresponding chloroacid anhydride.

**1-Aminoanthraquinone-2-sulfonic acid.** IMPERIAL CHEMICAL INDUSTRIES, LTD., A. DAVIDSON, W. W. TATUM and G. E. WATTS. Brit. 299,279, May 30, 1928.  $\alpha$ -Aminoanthraquinone is sulfonated with 1.0–1.5-mol. proportions of  $\text{H}_2\text{SO}_4$  and the acid sulfate so formed is baked (preferably *in vacuo* or in a current of hot gas) at a temp. of 210–245° or slightly higher depending on the state of purity of the starting material. A temp. of 240–5° with purified  $\alpha$ -aminoanthraquinone and 220–30° with "technical"  $\alpha$ -aminoanthraquinone is preferred.

***o*-Carboxamidoarylthioglycolic acids.** NORBERT STEIGER, ERWIN HOFFA and HANS HEYNA (to Grasselli Dyestuff Corp.). U. S. 1,712,365, May 7. Reduction of *o*-cyanoarylsulfonyl chlorides of the general formula  $\text{R}(\text{SO}_2\text{Cl})(\text{CN})$ , wherein R means a substituted aryl residue, can be carried out in such a manner, that the  $\text{SO}_2\text{Cl}$  group is reduced to the SH group, whereas simultaneously the CN group is converted into the carboxamido group  $\text{CONH}_2$ . The *o*-carboxamidoaryl mercaptans thus obtained yield when condensed in the usual manner with monochloroacetic acid in an alk. soln. *o*-carboxamidoarylthioglycolic acids of the general formula  $\text{R}(\text{CONH}_2)(\text{SCH}_2\text{CO}_2\text{H})$ . It is essential that during the whole process of reduction practically no N of the cyano group is split off in form of  $\text{NH}_3$ , as otherwise substances, namely mostly the corresponding *o*-carboxyarylthioglycolic acids, are formed. The cyanoarylsulfonyl chlorides are preferably dissolved in or dild. with a suitable org. solvent of an inert character such as  $\text{C}_6\text{H}_6$  or  $\text{PhCl}$ . As reducing agents Zn dust,  $\text{SnCl}_2$  or finely powdered Fe may be used with addn. of either strong mineral or org. acids. Strong HCl is especially suitable. Among the org. acids especially glacial HOAc, strong  $\text{CH}_3\text{CO}_2\text{H}$  and naphthalene-mono- and -polysulfonic acids are suitable. Probably as intermediates of the reduction process sulfonic acid compds. are formed. The *o*-cyanoarylsulfonyl chlorides which are used as starting materials may be prepd. by converting the corresponding *o*-aminoarylsulfonic acids according to Sandmeyer's reaction into the *o*-cyanoarylsulfonic acids and treating the latter compds. with  $\text{PCl}_5$  or an excess of chlorosulfonic acid. The new *o*-carboxamidoarylthioglycolic acids obtainable in a pure state with a good yield are important intermediates for the production of dye of the thioindigo series especially

when corresponding to the general formula  $\text{CX}:\text{C}(\text{CONH}_2):\text{C}(\text{SCH}_2\text{CO}_2\text{H}):\text{CH}:\text{CY}:\text{CZ}$  wherein X means H or an alkyl group, Y H or halogen or an alkyl group and Z H or halogen. 1-Methyl-2-carboxamido-5-chlorobenzene-3-thioglycolic acid, m. 172–4°; the production of 1-methyl-6-chloro-2-carboxamidobenzene-3-thioglycolic acid and of intermediates is also described in detail. U. S. 1,712,366 relates particularly to the production of 1-alkoxy-4-carboxamidobenzene-3-thioglycolic acids, which are white cryst. powders, sol. in hot water and the usual org. solvents. 1-Ethoxy-4-carboxamidobenzene-3-thioglycolic acid, m. 208–10°. U. S. 1,712,367 relates particularly to the 4-chloro-1-carboxamidobenzene-2-thioglycolic acid, m. 206°.

**Methyl alcohol.** CHARLES HENRY. Fr. 651,194, Feb. 9, 1926. Catalysts for the prepn of MeOH from CO and H are either (1) Sr and PbO ground together, preferably in the proportion of 3Sr:PbO, or (2) Zr and  $\text{Bi}_2\text{O}_3$ , preferably in the proportion of 3Zr: $\text{Bi}_2\text{O}_3$ .

**Apparatus for making acetaldehyde from acetylene.** I. G. FARBENIND. A.-G. Brit. 299,234, Jan. 2, 1928. App. for producing acetaldehyde from  $\text{C}_2\text{H}_2$  with use of a soln. of a Hg salt is formed of or lined with a Cr-Ni steel contg. Mo, *e. g.*, a steel contg. Cr 19–20, Ni 7–8 and Mo 2–3%.

**Chloroacetaldehyde.** I. G. FARBENIND. A.-G. Brit. 299,319, Oct. 22, 1927. Chloroacetaldehyde is produced without use of a catalyst, by introducing Cl gas and vinyl chloride into water and preferably keeping the temp. at 0–40° to avoid formation of by products. It is also preferable to exclude light which tends to cause formation of 1,1,2 trichloroethane. An inert gas such as  $\text{CO}_2$  or N may suitably be used as a carrier and mixing agent.

**Acetone.** CONSORTIUM FÜR ELEKTROCHEMISCHE INDUSTRIE GES. Brit. 299,330, Oct. 22, 1927. In acetone production by passing HOAc vapor over a heated catalyst, the use of iron app. is avoided and there are used instead materials which do not promote secondary reactions, *e. g.*, there may be used: Cu, ferro-Si and steels or other alloys rich in Cr or Ni. With these materials, temps. as high as 400–550° may be used which produce increased yields.

**Acetone.** HOLZVERKOHLEND.-IND. A.-G. (Koloman Róka, inventor). Ger.

475,428, Dec. 11, 1924. Acetone is prep'd. by the interaction of EtOH and H<sub>2</sub>O at 250–600° in the presence of metal-oxygen compds., particularly O compds. of Fe, Mn, and Cu. Preferably, an excess of H<sub>2</sub>O is used and a promoter, *e. g.*, CaCO<sub>3</sub> or MgO, is included in the contact mass. Cf. C. A. 23, 1419.

Ethylene from acetylene and hydrogen. I. G. FARBENIND. A.-G. Fr. 651,037, Mar. 20, 1928. See Brit. 294,787 (C. A. 23, 1910).

Purifying anthracene, naphthalene, etc., by selective catalytic oxidation of the impurities. A. O. JAEGER. Brit. 299,419, Oct. 26, 1927. Material such as anthracene, naphthalene and light oils contg. C<sub>6</sub>H<sub>6</sub> are purified by partial oxidation of the vapor with a limited quantity of O in the presence of oxidizing catalysts which may comprise various complex compds. of which a very large no. of examples are given.

Catalytic hydrogenation of methylaniline or other aromatic bases. WILHELM LOMMEL and THEODOR GOOST (to I. G. Farbenind. A.-G.). U. S. 1,712,709, May 14. In forming hexahydromethylaniline from methylaniline or in similar catalytic hydrogenations of aromatic bases, the reaction is arrested before hydrogenation of the whole mass is complete, hydrogenated products are sep'd. from unchanged base (suitably by distn.) and the unchanged base is then further hydrogenated. This manner of conducting the process serves to lessen the formation of by-products Cf. C. A. 23, 1420.

Hexamethylenetetramine. SCHIEFERWERKE AUSDAUER A.-G. Fr. 650,395, See Brit. 286,730 (C. A. 23, 397).

Mercaptobenzothiazole. HAROLD P. ROBERTS and HARRY A. MERKLE (to Rubber Service Laboratories Co.). U. S. 1,712,968, May 14. Substantially equimol. proportions of thiocarbonyl, S, and CS<sub>2</sub> are heated together in a container maintained under the pressure developed by the gases and vapors evolved in the reaction and at a max. temp. of about 275°.

2,3- and 2,5-Dichloro-4-amino-1-methylbenzene. WILHELM SCHUMACHER and CARL SEIB (to Grasselli Dyestuff Corp.). U. S. 1,712,173, May 7. 2-Chloro-4-acetamido-1-methylbenzene in a mixt. of glacial HOAc 4 and water 1 part is cooled (suitably to a temp. of about 0–5°) and treated with Cl, and the resulting solid ppt. is sep'd. from the soln.

1-Methyl-2,5-dichloro-4-aminobenzene. I. G. FARBENIND. A.-G. Fr. 650,561, March 7, 1928. The above is obtained by nitrating 1-methyl-2-amino-5-chlorobenzene in the presence of H<sub>2</sub>SO<sub>4</sub> replacing the NH<sub>2</sub> by Cl and reducing the NO<sub>2</sub> group. The diazotization may be carried out directly in the nitration liquor without previous sepn. of the nitroaminochloro comp'd. by introducing nitrite and pouring the mixt. into water.

Dimethylolurea. POLLOPAS, LTD., E. C. C. BALY and E. J. BALY. Brit. 299,487, June 24, 1927. Urea is condensed with CH<sub>2</sub>O (preferably using slight excess of CH<sub>2</sub>O) in cold aq. and very slightly alk. soln. An alkalinity of 0.01 N NaOH is suitable, with stirring for 24 hrs. at 15–20°. The product m. above 134° (usually at 138–40°).

Benzanthranyl sulfide, etc. OTTO BRAUNSDORF, EDUARD HOLZAPFEL and PAUL NAWIASKY (to Grasselli Dyestuff Corp.). U. S. 1,712,646, May 14. A benzanthranyl sulfide crystg. from PhNO<sub>2</sub> in dark yellow laminae, m. 347°, (C<sub>17</sub>H<sub>9</sub>O)<sub>2</sub>S, is made by reaction on benzanthrone with S chloride in PhCl in the presence of I at 90–140° and extg. with Na sulfide soln. In general, by causing a S halide, especially SHlg<sub>2</sub>, S<sub>2</sub>Hlg<sub>2</sub> (Hlg stands for halogen), or a mixt. of these compds. to act upon a benzanthrone, new S contg. derivs. of the benzanthrone series are obtainable in a good yield. Preferably, the reaction is carried out in the presence of a suitable solvent and a substance capable of promoting the reaction. It probably proceeds in such a manner that, besides benzanthranyl sulfide, intermediate products are formed which can be easily converted into benzanthranyl mercaptans and benzanthranyl sulfides, resp., by means of a caustic alkali or an alkali metal sulfide. From these products there may then be easily prep'd. in the usual manner corresponding derivs., for instance benzanthranyl disulfide, benzanthranyl thioethers or benzanthranylthioglycolic acids. The new compds. thus obtainable are valuable *intermediate products for the manuf. of dyes*. Several examples are given.

Ammonium formate; formamide. I. G. FARBENIND. A.-G. (Wilhelm Michael, inventor). Ger. 475,366, Aug. 15, 1925. Dry formates are dist'd. with NH<sub>4</sub>NO<sub>3</sub> *in vacuo*, whereby HCOONH<sub>4</sub> is obtained. If the distn. is conducted at atm. pressure, HCONH<sub>2</sub> is obtained. Cf. C. A. 22, 4132.

Purification of synthetic products. I. G. FARBENIND. A.-G. Fr. 650,543, Mar. 7, 1928. Synthetic substances such as MeOH, iso-BuOH, etc., are purified by treatment with oxidizing agents, *e. g.*, KMnO<sub>4</sub>, if necessary with the addn. of alkalis or org. bases and metal halides, with or without treatment with active purifying agents.

FRANK P. UNDERHILL

**The effect of emulsification on the peptic synthesis of protein.** H. WASTENEYS AND H. BORSOOK. *Colloid Symposium Monograph* 6, 155-72(1928).—The literature is reviewed. Pepsin digests of egg albumin, which no longer gave a ppt. with  $\text{CCl}_3\text{CO}_2\text{H}$ , were brought to  $p_H$  4 with concd. alkali, filtered, and concd. to 25% (based on the original protein). To 10 cc. of concd. digest were added 1 cc. of 10% aq. pepsin soln. and 1 cc. of emulsifying agent. After incubation (usually 24 hrs.) at  $37^\circ$ , the synthesized protein was washed on a filter and its amt. detd. by the Kjeldahl method. Benzaldehyde, benzoic acid, benzene, toluene and chloroform definitely accelerate synthesis; talc powder,  $\text{BaSO}_4$  and kieselguhr have slight accelerative effect; oleic acid and olive oil do not accelerate. Effective substances induce some protein synthesis even in absence of pepsin. Under optimum conditions, accelerators increase the rate merely, not the amt. of protein synthesis, though in some cases they also increase the amt. The synthesized proteins vary in their rate of hydrolysis by  $\text{HCl}$  and in base-combining capacity.

JEROME ALEXANDER

**Specific nature of invertase.** R. WEIDENHAGEN. *Z. Ver. deut. Zucker-Ind.* 1928, 406-18.—The sucrose-splitting enzymes in *Aspergillus oryzae* (the source of taka diastase), *A. niger*, *Penicillium glaucum*, and pigs' intestine are all capable of decomposing raffinose into melibiose and levulose at rates which are of the same order as those observed in the hydrolysis of sucrose. There are therefore no grounds for assuming that the invertase of taka-diastase or the other materials mentioned represents a different type (gluco-invertase) from that present in yeast (fructo-invertase).

B. C. A.

**Enzymic sucrose cleavage.** RUDOLF WEIDENHAGEN. *Inst. Zuckerindustrie, Berlin. Naturwissenschaften* 16, 654-5(1928); *Z. Ver. deut. Zucker-Ind.* 1928, 539-42.—It has previously been proposed (cf. preceding abstr.) that cleavage of disaccharides is induced by simple glucosidases. For mixed disaccharides two enzymes can attack the substance. It is now found that Willstätter and Bamanns' (*C. A.* 20, 1245) sepn. of "maltase" and "saccharase" actually is a sepn. of  $\beta$ -h-fructosidase and  $\alpha$ -glucosidase: the maltase gave, for optimum  $p_H = 7.0$ , hydrolysis of sucrose of the order of magnitude of maltose cleavage, none at  $p_H = 4.6$ , the optimum for fructosidase action. At  $p_H = 7.0$  no raffinose hydrolysis occurred as expected; however, melezitose cleavage resulted if sufficient active  $\alpha$ -glucosidase ("maltase") was present.

B. J. C. VAN DER HOEVEN

**The specificity and mode of action of sugar-splitting enzymes.** RUDOLF WEIDENHAGEN. *Z. Ver. deut. Zucker-Ind.* 79, 115-54(1929).—A complete review is given of the theories of enzyme action, as well as of the specificity and the mode of action of the sugar-splitting enzymes.

F. CAMPS-CAMPINS

**Enzymes of the seeds of *Strophanthus kombe* and their influence on k-strophanthin.** PIETRO DI MATTEI. *Univ. Roma. Arch. intern. pharmacodynamie* 35, 113-35 (1928).—The seeds of *Strophanthus kombe* contain the following enzymes: lipase, esterase, emulsin, strophanthinase, phenol-oxidase, peroxidase, catalase, reductase. It is not possible to demonstrate alcohol-oxidase in the presence of glutathione.

DAVID DAVIDSON

**The individuality of the trypsin complex. I. Comparative studies on the behavior of various substrates toward various trypsin-kinase preparations at different  $p_H$  values.** EMIL ABDERHALDEN AND OSKAR HERRMANN. *Univ. Halle. Fermentforschung* 10, 474-7(1929).—Trypsin prepn. obtained from powd. pancreas by the Waldschmidt-Leitz procedure, although uniformly active toward casein, show marked differences in the extent to which they hydrolyze halogenacylamino acids or tripeptides. One prepn. gave 18% hydrolysis with chloroacetyl-*dl*-leucine and 72% with chloroacetyl-*l*-phenylalanine, while a 2nd prepn. gave hydrolyses of 15% and 45%, resp., under identical conditions. Different prepn. respond differently toward changes in  $p_H$ . From chloroacetyl-*l*-tyrosine the pptd. tyrosine in one instance was 51 mg. at  $p_H$  7.8 and 35 mg. at  $p_H$  8.4; in another instance 10 mg. at  $p_H$  7.8 and 8 mg. at  $p_H$  8.4. One prepn. which was more active toward the tripeptide *dl*-leucylglycyl-*dl*-leucine was less active toward chloroacetyl-*l*-tyrosine than another prepn. In general, the halogenacylamino acids are attacked more readily at  $p_H$  7.8 and the polypeptides more readily

at  $p_H$  8.4. These observations would indicate that trypsin-kinase is not an individual enzyme complex. II. Attempts to separate enzymes with different actions in the preparation of "trypsin" from pancreas powder. EMIL ABERHALDEN AND ERNST SCHWAB. *Ibid* 478-80.—By changing the  $p_H$  at which the adsorption on  $Al(OH)_3$  is performed in the Waldschmidt-Leitz procedure for purification of trypsin, an attempt was made to sep. the trypsin complex into 2 components, the protease and possibly a polypeptidase. Glycerol ext. of pig pancreas was freed from enterokinase by adsorption on pptd. casein and the centrifuged mother liquor brought to  $p_H$  4.7 with acetate buffer. Three adsorptions on  $Al(OH)_3$  removed the erepsin. The  $p_H$  was then brought to 5.6 and another adsorption performed with  $Al(OH)_3$ , followed by elution with  $NH_4OH$ . This eluate was entirely inert toward *dl*-leucylglycine, *dl*-leucylglycyl-*dl*-leucine and casein, but readily attacked chloroacetyl-*l*-tyrosine, chloroacetyl-*l*-phenylalanine, chloroacetyl-*l*-leucine and the  $PhNCO$  deriv. of glycyl-*dl*-leucine. However, the trypsin component could not be obtained free from all action on acylamino acids, despite repeated adsorptions of the mother liquor with  $Al(OH)_3$ , although its activity toward acylamino acids was greatly diminished without loss of activity toward casein. It is evident that trypsin contains in addn. to its protease one or more enzymes analogous to the "histozyme" which splits hippuric acid into glycine and  $BzOH$ . III. Comparative experiments on the rate of hydrolysis of halogenacylamino acids and polypeptides by the action of different preparations of "trypsin" at different  $p_H$  values. EMIL ABERHALDEN AND WALTER ZEISSET. *Ibid* 481-90.—The chloroacetyl, bromoisovaleryl and bromoisocapronyl derivs. of a no. of amino acids and peptides were tested for cleavage by one and the same trypsin-kinase prepn. at  $p_H$  8.4 and 7.8, resp. Almost without exception the cleavage was greater at  $p_H$  7.8. Certain halogenacyl derivs. which are quite resistant to ordinary preps. of trypsin-kinase, e. g., the chloroacetyl derivs. of valine and its peptides and the bromoisovaleryl derivs. of glycine and the glycyglycines, were tested with the trypsin-free enzyme obtained by adsorption at  $p_H$  5.6. No noteworthy increase in hydrolysis was observed. A. W. DOX

Alcohol fermentation. XIX. Some microorganisms in the maceration juice capable of fermentation. S. KOSTYCHEV AND O. SHULGINA. *Inst. Biochem., Leningrad. Z. physiol. Chem.* 182, 50-6 (1929); cf. *C. A.* 23, 2727. A no. of visible organisms are known to exist also in invisible forms capable of passing through a Chamberland filter. Filtration through porcelain can therefore no longer be regarded as a sure method of sterilization. Proof of the enzymic nature of a fermentation now requires a neg. fermentation test when the fermenting medium is inoculated into a sterile medium; the absence of visible organisms is not conclusive. Filtrates from yeast suspensions are now shown to contain visible organisms which ferment glucose into  $CO_2$  and  $EtOH$ . These have probably passed through the filter in their invisible form. A serious oversight in Buchner's classic expts. with "zymin" is that he undertook to demonstrate sterility before, instead of after, the fermentation. Yeast juice contains organisms which are active even in the presence of  $PhMe$ . They contain also a stimulator liberated from the cells, and this stimulating substance enables insignificant quantities of living cells to function with extraordinary vigor. Enzymic fermentation may possibly occur simultaneously with the fermentation by living cells, but a cell-free fermentation has yet to be demonstrated. A. W. DOX

Chemistry of the blood pigment. IX. The linkage between protein and prosthetic group in hemoglobin. FELIX HAUROWITZ AND HEINRICH WAELSCH. *Z. physiol. Chem.* 182, 82-96 (1929); cf. *C. A.* 22, 1167.—The xpts. of Hill and Holden (*C. A.* 21, 2004), which showed that native globin and hemin unite to form a hemoglobin, were corroborated by gasometric detn. of the reversible O consumption of the product. A genuine hemoglobin is formed through a methemoglobin stage and this has the power of binding mol. O. Under the same conditions denatured globin yields cathemoglobin which lacks this power of taking up O. Since dimethylated hemin and hydrogenated hemin also unite with native globin, it is evident that the carboxyls and the unsatd. side chains do not function in this linkage. The union occurs also in the complete absence of cholesterol. The slight change which the spectrum of porphyrins undergoes on addn. of globin cannot be considered evidence of the formation of a chem. compd., "globin-porphyrin," since this change is not specific and occurs even with serum protein. The view is upheld that the linkage between the 2 components of hemoglobin occurs through the Fe atom by means of coordinative valence. Native globin from the steer is a slightly acid protein. Its isoelec. point is at  $p_H$  6.9-7.0, and its coagulation temp. is  $47^\circ$ . In other respects it shows the typical properties of an albumin. The slight differences between the original and the resynthesized hemoglobin, which coagulate at  $47^\circ$  and  $63^\circ$ , resp., are attributed to a partial

denaturing which the protein component undergoes in the course of isolation.

**Enzymic hydrolysis of melezitose and turanose.** T. ÅGÅRD. *Tids. Kemi Bergvesen* 8, 5-9, 16-20, 35-9(1928).—Results are given of expts. in which 9 specific enzymes act upon melezitose and turanose.  $\beta$ -Glucosidase, rhamnodiastase and invertase do not hydrolyze the reducing disaccharide turanose, which is formed by slight hydrolysis of melezitose, and consists of a mol. fructose and a mol. glucose. Turanose is easily dissoed. by  $\alpha$ -glucosidase. The disaccharide must then be regarded as a  $\alpha$ -glucoside of fructose. Melezitose is not dissoed. by invertase. The trisaccharide is dissoed. by *Aspergillus niger*, but the hydrolysis is incomplete. Melezitose is dissoed. into fructose and glucose by  $\alpha$ -glucosidase. The expts. do not confirm the assumption of Kuhn and van Grundherr (*C. A.* 21, 64) that there is a "glucoinvertase" in *Aspergillus niger* which causes dissoen. of melezitose into turanose and glucose, and that ordinary invertase is a "fructo-sucrase."

**Relationship of the physical properties of chemical substances to their action on microorganisms.** TH. SABALITSCHKA. *Arch. Pharm.* 267, 272-90(1929).—An address before the Ger. Pharm. Assocn.

**The amide nitrogen of blood.** IV. A method of expressing results based upon the protein content of blood. SIDNEY BLISS. McGill Univ., Montreal. *J. Biol. Chem.* 81, 405-6(1929); cf. *C. A.* 23, 1946.—The amide N of blood should be expressed in terms of mg. per 100 g. of blood protein. A method of detg. the amide N of blood is given.

**Electrostatics as a separate realm of investigation in biochemistry.** RUDOLF KELLER. *Kolloidchem. Beihefte* 28, 219-34(1929).—The recent advances are summarized.

**Fundamental principles and limitations to biological  $p_H$  determinations.** F. LEUTHARDT. *Kolloidchem. Beihefte* 28, 262-80(1929).—L. considers the importance of  $p_H$  considerations in biological systems to have been over-emphasized. The cell is a system in which purely thermodynamic considerations are inapplicable and in which statistical variations must be considered.

**Vasilii Leonidovich Omelyanskii (1867-1928).** LJUDEVIT GUTSCHY. *Arch. Hem. Farm* 3, 76-8(1929).—A biography.

**The physico-chemical principles of the irritability of pigment, muscle and glandular cells.** N. K. KOLTZOV. *Rev. gén. sci.* 40, 165-71(1929).—The contraction and expansion of living cells may be controlled when they are washed in solns. which are isotonic with the Tyrode or the Ringer-Locke physiol. solns. by varying the ratio of the concn. of the cations. Expts. were made on melanophore cells of the Teleostei and Batrachia by microscopic study; on smooth muscle tissue of mammals by detg. the rate with which the solns. washed through the organs; and on the salivary glands of the dog by the rate of secretion of saliva. With one exception, an increase in Ca-ion concn. favored contraction, and in all cases an increase in Na-ion concn. favored expansion. The action of K and Mg ions varied, but they were less effective than Na and Ca. Pituitrin caused expansion, and adrenaline caused contraction. A concn. of 1:10,000,000 of adrenaline brought about complete contraction, a reaction which might serve to standardize adrenaline preps.

**The relations between dielectric constant and physiology.** JOS. GICKLHORN. *Kolloidchem. Beihefte* 28, 328-32(1929); cf. *C. A.* 22, 2597.—In the phys. chemistry of colloids the dielec. const. has an important role. Its influence on the application of the law of Coulomb, on formation of potentials, dissoen. dispersion of colloidal particles, satn. of soln., miscibility of liquids, its relation to pressure and sp. gr. and concn. are emphasized. Hence it has influence in physiology on the stability of solns., imbibition, viscosity, dispersion, sp. gr. and refraction. Important is the high dielec. const. of H<sub>2</sub>O as a medium of biochem. reactions and the fact that these reactions occur in an anisotropic space.

**Studies on lipoids.** III. Lipoid content of butter. BRUNO REWALD. *Biochem. Z.* 202, 391-3(1928); cf. *C. A.* 23, 855.—The lipid content of butter is shown to be much higher than generally assumed. In every case investigated, our butter prepn., also German and Danish articles, show a lipid content of over 1% and in one instance even as high as 1.7%. The nutrition of the cows is thought to be responsible for these differences in lecithin. The variation is not due to the fact that lecithin remains behind in the process of butter making, the skimmed milk showing less than 0.01% of lecithin. IV. Effect of heating on the lipoids. *Ibid* 394-8.—Fresh egg yolks were well mixed and 3 portions of 80 g. each used for the analyses: (1) without any preliminary treatment; (2) after heating for 30 mins. on the water bath; (3) after baking for 20

mins. with the lipid-free coconut butter. The material was first extd. 6 times with cold acetone and the acetone ext. was redissolved in ether. The residue after acetone extn. was extd. with 96% alc. 4 times, the last time with the addn. of benzene. All together 2400 cc. acetone and 2000 cc. alc. were used up in the extn. As a const. result it was noted that cold acetone exts. large amts. of lipid material, the more so the greater the amt. of fat present. The analyses further show that warming and even heating causes no immediate increased destruction of lipoids. On the contrary, in expts. with various organs (liver, kidney, meat) the boiling leads to a small loss of lipid material which, however, in proportion to the low lipid content of the organs, is very significant. This is not the result of a decompn. of the lipid, but of a soln. during boiling. V. Preparation of lipoids from chlorophyll-containing organs. *Ibid* 399-402.—Finely cut plant material (800 g.) was extd. 9 times with 1 l. quantities of anhyd. cold acetone. The residue represented 1.31% of the original substance, and, according to its P content, had 11.67% lipid. This again shows that cold acetone exts. much lipid material. This could be sepd. from a highly concd. acetone ext. by cooling to  $-8^{\circ}$ . The alc. extn. of the acetone-extd. residue contained 5.03% phosphatides. From the analyses it is calcd. that fresh salad with a 96% water content contains about 1.1% lipid. S. M.

Absolute absorption spectrum of the respiratory enzyme. OTTO WARBURG AND ERWIN NEGELEIN. *Biochem. Z.* 204, 495-9(1929); cf. *C. A.* 23, 773, 856.—A correction of data reported in an earlier paper (*C. A.* 23, 773). S. MORGULIS

Sulfatase. X. FRITZ WEINMANN. Kaiser Wilhelm-Inst. für Biochem., Berlin-Dahlem. *Biochem. Z.* 205, 214-8(1929).—The  $H_2SO_4$  esters of aromatic hydroxyl compds. of benzene, naphthalene, indole, quinoline, etc., are split by sulfatase, while the  $H_2SO_4$  esters of aliphatic and hydroaromatic alcs. are not affected. Furthermore, K myronate is not attacked by sulfatase from fungi, but is split by the enzyme obtained from animal tissues. The K salt of the  $H_2SO_4$  ester of 3-methylcyclohexylphenol is completely hydrolyzed by sulfatase. S. MORGULIS

The disaggregating activity of pepsin in addition to its more certain hydrolytic function. MAX FRANKEL. Hebraische Univ., Jerusalem. *Biochem. Z.* 207, 53-65(1929).—The question whether an "induction period" precedes the hydrolytic phase of the pepsin activity during which no chemical change occurs but only one of colloidal aggregation, is answered in the negative. S. MORGULIS

The rate of sedimentation of erythrocytes from the standpoint of the Hofmeister ion series. II. D. VON KLOBUSTZKY. Kgl. ungar. Elisabeth-Univ., Pécs. *Biochem. Z.* 207, 80-90(1929).—The anions of the Hofmeister salts influence in hypertonic soln. the elec. charge, viscosity and sp. gr. of plasma as well as the vol. and sp. gr. of the red cells. These effects correspond completely to those observed in the matter of the rate of sedimentation, the dominant factor in which is the alteration in the charge. The effect of the cations is irregular; this is attributed to the fact that these scarcely exert any action on the elec. charge. S. MORGULIS

Oxidation of glucose and glyocoll with alkaline copper solutions. HARRY LUNDIN. Harvard Univ. *Biochem. Z.* 207, 91-106(1929).—Glyocoll in large amt. inhibits the oxidation of glucose by alk. Cu solns. contg. carbonate in the range of  $p_H$  9.1-9.6, as is the case in the Folin reagents. The inhibition of the oxidation by glyocoll is greater the lower the  $p_H$ . If the Cu reduction is carried out with a mixt. of glucose and glyocoll at a  $p_H$  of 9.8 or above, at which the glyocoll no longer hinders the glucose oxidation, the total reduction is approx. equal to the sum of each component. The oxidation of glyocoll by the Folin type of carbonate alk. Cu solns. increases with the  $p_H$  and also with the duration of the boiling, the amt. oxidized depending upon the concn. of the carbonate. The optimum condition for oxidation of glucose is at  $p_H$  9.2-9.8. It is therefore necessary to raise the  $p_H$  of the Folin reagents by the addn. of NaOH in order to obtain reproducible results. S. MORGULIS

Oxidation of glucose and glyocoll with alkaline copper solutions in the presence of boric acid. HARRY LUNDIN. Harvard Univ. *Biochem. Z.* 207, 107-19(1929).—Boric acid inhibits the oxidation of glucose by alk. Cu solns. of the type of Folin's reagents, this effect being greater the lower the  $p_H$  within the range 9.1 to 10.5. If the ratio between boric acid and glucose is very large (400-500) the glucose may not be at all oxidized within that range. Increasing the time of boiling acts in the opposite direction. Cu reagents contg. boric acid oxidize amino acids, creatinine, etc., to the same extent as under similar conditions occurs without the boric acid. The Folin-Wu reagent to which 56 g. boric acid or 85 g. borax is added per l. is not at all reduced by small quantities of glucose but is reduced by glyocoll, creatinine, etc. S. M.

Physical decolorization of bile. HUGO WIT. Univ. Wien. *Biochem. Z.* 207, 141-5(1929).—The decolorization of bile through adsorption was tested by means of

powdered adsorbents (animal charcoal, kaolin, talc or kieselguhr) or gel-like adsorbents ( $\text{Fe}(\text{OH})_3$ ,  $\text{Al}(\text{OH})_3$ , or silicic acid gel). The bile was filtered through these various adsorbents. The filtrate through  $\text{Fe}(\text{OH})_3$  or  $\text{Al}(\text{OH})_3$  was water-clear, whereas through the acid silicic gel the soln. was little decolorized. The adsorption of the bile pigments is thus primarily dependent upon the electrochemical condition of the adsorbent. The amphoteric animal charcoal was the best adsorbent of the first group, the salt-like kaolin, talc or kieselguhr being very much less effective. The reaction of the bile is very important, and the addn. of acid, by giving to the adsorbent a pos. charge, increases its adsorption. The inhibiting action of the bile salts on the decolorization of the bile is attributed to the fact that this is brought about by the adsorption of similarly charged ions. The bearing of these physicochemical findings on problems of the physiology and pathology of the gall bladder is discussed. S. MORGULIS

The effect of protein on the oxidative and catalytic properties of inorganic catalysts. M. I. GALVIALO AND R. DOBROTVORSKA. Military Med. Acad., Leningrad. *Biochem. Z.* 207, 146–50(1929).—Protein is not an indifferent component of a system containing metals, but it increases the oxidative capacity of the metals as well as the catalase action of some of these. This effect is attributed to the protection of the colloidal protein to the suspension of the metal in the soln. S. MORGULIS

Water-soluble phosphatide and the Nadi oxidase reaction. M. GUTSTEIN. Univ. Berlin. *Biochem. Z.* 207, 177–85(1929).—There is obtained from peas and yeast by means of dialysis against water a water-sol. phosphatide, which gives a pos. Nadi oxidase reaction *in vitro* and reduces  $\text{KMnO}_4$ . These reactions (oxidase and reduction) are obtained with extremely small quantities of the phosphatide (0.04 mg.) which is 20 times as active as a similar quantity of yeast. The oxidase action of the phosphatide *in vitro* is thermostable and resistant to HCN which is not the case in the living cells. This oxidase reaction of the phosphatide is specific, benzidine, oxidase, peroxidase and catalase reactions being neg. S. MORGULIS

Isolation of methylglyoxal in lactic acid fermentation. CARL NEUBERG AND MARIA KOBEL. Kaiser Wilhelm-Inst. für Biochem., Berlin-Dahlem. *Biochem. Z.* 207, 212–62(1929).—Exts. made from plasmolyzed or autolyzed mass cultures of *Bacillus delbrücki* produce  $\text{CH}_3\text{COCHO}$  from hexosediphosphoric acid. Similar results are obtained with exts. from acetone or alc.-ether preps. of the bacilli. The  $\text{CH}_3\text{COCHO}$  yield is extraordinarily large, and in 6 balance expts. an av. of 83.2% of the sugar was recovered as  $\text{CH}_3\text{COCHO}$ . This proves that the hexose mol. breaks up into 2 mols. of  $\text{CH}_3\text{COCHO}$ . As substrate the easily sol. and stable Mg salt of hexose-diphosphoric acid was used. For the prepn. of the enzyme usually a quantity of the pure culture of the bacteria corresponding to 14 g. dry substance was suspended in 200 cc.  $\text{H}_2\text{O}$  contg. 10 cc. toluene. After 2 days at  $37^\circ$  a clear supernatant fluid was obtained which was very active. A quicker method of prepn. consisted in plasmolyzing a quantity of fresh bacteria with salt soln., glycerol or acetic ester. But the most potent enzyme prepn. for producing methylglyoxal was made by rubbing in a mortar a quantity of centrifuged bacteria in a mixt. of 450 cc. alc. and 150 cc. ether. This was filtered off and dried in a desiccator. Nine g. of this dry bacterial mass was triturated in a mortar about 5 mins. with 18 cc.  $\text{H}_2\text{O}$  and 3.6 g. powdered  $\text{NaCl}$ , dild. to 360 cc. with water and centrifuged. The methylglyoxal was sepd. from the exptl. mixt. by pptn. with 2,4-dinitrophenylhydrazine-HCl after the mixt. had been deproteinized. The ppt. of the methylglyoxal hydrazone is centrifuged off and washed with dil. HCl,  $\text{H}_2\text{O}$  and alc., and finally recrystallized from pyridine, then from nitrobenzene and weighed after drying at  $120^\circ$ . S. MORGULIS

Lactic acid fermentation of warm-blooded tissue. I. Conditions necessary for the fermentation in liver tissue. OTTO ROSENTHAL. Inst. für Krebsforschung, Charité, Berlin. *Biochem. Z.* 207, 263–97(1929).—Lactic acid fermentation is the result of asphyxia of liver tissue, the carbohydrates of the cells furnishing the substrate. This fermentation never occurs in starved rats; the condition of being well nourished is essential. In some cases the aerobiosis was ineffective because the conditions were already previously present for the fermentation. The fetal liver could not ferment but the age at which the fermentative process appears was not detd. The max. effect of the aerobic period upon the intensity of fermentation after subsequent asphyxia is reached in 15 mins. and extension of aerobiosis for 30 mins. had no further effect. The body temp. of  $37.5^\circ$  is apparently necessary to develop the action of the aerobiosis, since it was absent at  $0$ – $20^\circ$ . Neither does this fermentation occur if during the preliminary aerobiosis period K- and Ca-free Ringer soln. is used as a medium. The substitution of fresh, homologous serum for Ringer soln. has no effect on the aerobiosis so far as the subsequent fermentation under anaerobiosis is concerned. S. MORGULIS

**Iodine as a biogenous element. XVIII.** The mode of combination of iodine in milk. K. SCHARRE AND J. SCHWAIBOLD. Tech. Hochschule, München. *Biochem. Z.* 207, 332-40(1929); cf. *C. A.* 23, 661.—The I always found in milk is only partly in the form of inorg. compds. Mostly it is bound to the org. substances of the serum which is free from protein, fat or lactose; a smaller and variable quantity is in combination with protein, while the fat contains no I or such small traces as to be of no significance. Feeding iodized protein changes these relations very slightly. The administration of large quantities of KI causes a considerable rise in the inorg. I. Feeding iodized fatty acids results in the transfer of the largest part into the milk as iodized fat. S. M.

The activation of insulin by yeast press juice. ERHARD GLASER AND GEORG HALPERN. Pharmakognostisches Inst., Wien. *Biochem. Z.* 207, 377-83(1929).—An insulin activator was prepd. from yeast press juice boiled for 8 hrs. The boiled juice itself has no hypoglucemic effect. By concg. the juice a more potent insulin activator can be obtained. The activation takes place only in a slightly alk. medium ( $p_H = 7.8$ ), if the juice is added to the insulin about 16 hrs. before it is used. When purified by means of a Pb pptn. the active component passes into the eluent. However, the substance does not prolong the time of action of the insulin. It is assumed that part of the insulin in lab. preps. is inactivated and cannot, therefore, produce any effect. S. MORGULIS

**Enzymes and light. XIV.** Studies on the influence of temperature on the light action. LUDWIG PINCUSSEN AND TAKEO OYA. Krankenhaus am Urban, Berlin. *Biochem. Z.* 207, 410-5(1929).—The optimum  $p_H$  of 5.9 at which taka-diastase hydrolyzes starch is maintained at 15° and 45°. The radiated samples show less activity than those kept in the dark, but at  $p_H$  6.68 there was no loss of amylase activity at 45° when the sample was in the dark. Likewise, at  $p_H$  7.15 both the radiated and dark sample showed greater activity at 50° than at 15°. Expts. show that this is not due to a reactivation. S. MORGULIS

**Changes in metabolism under the influence of radiation. IV.** Studies on the fat content of organs. LUDWIG PINCUSSEN AND EUGEN ZUCKERSTEIN. Krankenhaus am Urban, Berlin. *Biochem. Z.* 207, 426-31(1929).—In the serum of radiated animals the total ether ext. is definitely increased but the cholesterol level is unchanged. In the heart the fat content is markedly reduced in the radiated animals and there is no difference between the animals radiated with or without eosin. The cholesterol, on the contrary, markedly increases in eosinized animals when radiated. In the liver the ether ext. is greatly reduced, especially in the eosinized animals. The cholesterol content is somewhat higher, especially in radiated eosinized animals. In the kidney no difference in the total fat content is observed except in eosinized animals. The cholesterol is definitely higher in the radiated animals. In eosinized radiated animals the cholesterol is, like the total fat, appreciably lowered. Similarly in the muscles the quantity of fat is little affected except in those treated with eosin, while the cholesterol content in the radiated and non-radiated animals is the same. In general, the radiated animals show a higher content of the serum in ester-splitting enzymes. S. MORGULIS

**Malt amylase. V.** Determination of dextrin-forming and saccharifying action of amylase and a comparison of the two effects. TH. SABALITSCHKA AND R. WEIDLICH. Univ. Berlin. *Biochem. Z.* 207, 476-93(1929).—A method is devised to det. the velocity of dextrin formation and dextrin hydrolysis during the action of amylase on starch. The method depends upon the use of an artificial color scale for comparison with the color produced by I. By this method, the monomol. equation being used, the activity of various amylases can be compared. The const. of the hydrolysis of dextrin is obtained from detns. of the maltose formed. The ratio of the 2 velocity const. (dextrin formation and saccharification) in the case of different malt amylase quantities was 1.12 ( $\approx 0.14$ ). S. MORGULIS

The influence of hydrogen-ion concentration upon the inactivation of urease by some heavy metals. MATSUNOSUKE KITAGAWA. Kyushu Imperial Univ., Fukuoka. *J. Biochem. (Japan)* 10, 197-205(1929).—An increasing  $p_H$  of the medium intensifies the inactivation of urease by heavy metal ions so that a metal like Zn which is relatively less injurious inhibits the urease reaction on the alkaline side from  $p_H$  6.0, whereas more injurious metals like Cu or Hg are inhibitory both on the acid and alk. side. The effect is parallel to the influence of  $p_H$  on the combination of protein with heavy metals. Free I is very injurious to urease as compared with KI. Inactivation by KI increases on the acid side. S. MORGULIS

**Protamine. I.** RYOZO HIROHATA. State Med. Coll., Formosa. *J. Biochem. (Japan)* 10, 251-8(1929).—A protamine was isolated from the sperm of *Mugil japonicus*. It probably contains no aromatic amino acids nor any basic amino acids except arginine.

which constitutes more than 70% of the total free protein. Relatively large amts. of mono-amino acids sol. in EtOH and MeOH are present. This protamine is designated "Mugiline  $\beta$ " as it seems to differ from the protamine isolated from *Mugil cephalus*.

S. MORGULIS

The effect of proteolytic enzymes on benzoyl and desamino derivatives of polypeptides. TSUTOMU KAWAI. Univ. Kyoto. *J. Biochem.* (Japan) 10, 277-310 (1929); cf. *C. A.* 23, 2196.—Glycyl-*dl*-phenylalanine *dl*-leucylglycine, glycyl-*l*-phenylalanine and glycyl-*l*-leucine are easily split by erepsin but not by trypsin. Benzoyl-glycylglycine is not hydrolyzed by purified or impure erepsin. The benzoyl derivs. of the other dipeptides are very markedly hydrolyzed by the crude erepsin. Trypsin hydrolyzes the benzoyl derivs. of glycyl-*dl*-phenylalanine, *dl*-leucylglycine, glycyl-*l*-phenylalanine and glycyl-*l*-leucine, the hydrolysis of racemic compds. proceeding asymmetrically. Since the products of tryptic hydrolysis of benzoylglycyl-*dl*-phenylalanine are hippuric acid and *l*-phenylalanine it is obvious that the splitting must occur at the peptide linkage. Benzoylglycylglycine is not hydrolyzable either by erepsin or by trypsin. The hydrolyzable dipeptide benzoyl derivs. are affected not only by Grüber's trypsin but especially by trypsin purified by adsorption, at the peptide linkage. In the case of dipeptides like glycyl-*dl*-phenylalanine and *dl*-leucylglycine which are not affected by trypsin, such hydrolysis does occur when the free  $\text{NH}_2$  group is attached to a benzoyl radical. This fact led to expts. with tripeptides in which the amino acid was in combination with dipeptides not hydrolyzed by trypsin. These were again hydrolyzable by trypsin. Benzoyldiglycylglycine is not at all split by trypsin. Desaminated dipeptides like the benzoyl derivs. are not hydrolyzed by erepsin. Desaminated polypeptides were prepd. which generally were very resistant to the action of erepsin, while some were hydrolyzed by trypsin.

S. MORGULIS

Hematoporphyrin hemolysis. HASHIME KAWAI. Biochem. Inst., Imp. Univ., Tokyo. *J. Biochem.* (Japan) 10, 325-50 (1929).—When red blood corpuscles are hemolyzed by exposure to light in the presence of hematoporphyrin no substance is found capable of producing hemolysis. In dil. soln. hematoporphyrin is absorbed by erythrocytes while in concd. soln. it seems to combine with them. Hemolysis caused by hematoporphyrin is often observed in corpuscles with a high content of acid-sol. phosphoric acid and is accompanied by decompn. of org. phosphoric acid. This, however, does not occur in the disintegration of the stroma.

S. MORGULIS

Serum albumin and complex ions. S. G. T. BENDIEN AND L. W. JANSSEN. *Rec. trav. chim.* 47, 1042-57 (1928).—Serum albumin is pptd. by  $\text{NH}_4$  or Na vanadate acidified with AcOH. The theory that the flocculation is due to an albumin sol bearing a positive charge combining with a  $\text{V}_2\text{O}_5$  sol bearing a negative charge was not confirmed by the present investigation. It was found that the flocculation was max. in a definite zone at const. ratio between  $\text{Na}_2\text{VO}_4$  and AcOH. This zone lies near the isoelec. point. On both sides of this zone the high charge of the albumin hinders the flocculation. This zone is wider for globulin than for albumin. Serum albumin can be sepd. into diff. fractions, which in the same mixt. flocculate at diff.  $p_{\text{H}}$  values. The speed of cataphoresis and the viscosity of these serum fractions were detd. when dissolved in different electrolytes and at different  $p_{\text{H}}$  values.

GEO. W. MUHLEMAN

The chemical and biological changes induced by x-rays in body tissues. MONTROSE T. BURROWS, LOUIS H. JORSTAD, EDWIN C. ERNST. *Radiology* 11, 370-7 (1928); cf. *C. A.* 22, 2380.—One action of x-rays in tissues is to remove their lipid content. One of the chief actions of x-rays in destroying cancer may, therefore, be the removal of lipoids from the cancer cells and from the surrounding tissues. These lipoids are necessary for the growth of cancer cells; without their presence the cancers degenerate quickly.

E. H. QUIMBY

The direct and indirect action of radiation on cancer tissues. A. LACASSAGNE. *Radiology* 11, 393-402 (1928).—Three theories have been advanced to explain the destruction of cells under the influence of radiation: a direct action, a local indirect action and a general indirect action. For normal cells the first method is generally admitted to be correct. L.'s expts. tend to show that this is also the case for cancer cells.

E. H. QUIMBY

The biology of the bog lakes as examined on the bog dams of the Iser mountains. FRITZ GESSNER. *Arch. Hydrobiol.* 20, 1-64 (1929).—A study on the phys., chem. and biol. properties of 2 true bog lakes formed by the construction of dams. These lakes have an exceptionally high degree of acidity ( $p_{\text{H}}$  5.1-5.7). The  $p_{\text{H}}$  decreased from the surface toward the bottom. G. concludes that in lakes of this type the acidification occurred from the bottom, the degree of acidity depending on the location of the lake,

the quantity of water flowing through and the age of the lake. As to the latter instance it is assumed that the  $p_H$  increases with increasing age. G. SCHWOCH

The specificity of animal proteases. XIV. The structural assumption for specific hydrolysis by trypsin, trypsin-enterokinase and erepsin. E. WALDSCHMIDT-LEITZ, W. KLEIN AND A. SCHÄFFNER. Tech. Hochschule, Prag. *Ber.* 61B, 2092-6(1928); cf. C. A. 22, 2381.—The enzymes were used on a series of 13 di- and tri-peptides. Benzoylglycylglycine was acted on only by trypsin-enterokinase. The latter acted more strongly than trypsin alone on bromisocapronylglycyltyrosine, chloroacetylphenylalanine, chloroacetyltyrosine, carbethoxyglycyltyrosine, benzoylglycyltyrosine,  $\beta$ -naphthalenesulfonylglycyltyrosine,  $\beta$ -naphthalenesulfonyltyrosylglycine and phenylalanylarginine. The erepsin acted only on phenylalanylarginine and histidylglycine. J. J. WILLAMAN

Enzymic relations of pectin. J. J. WILLAMAN. *Univ. of Minnesota, Studies Biol. Sci.* 6, 333-41(1927).—A review of the history, occurrence and biol. significance of protopectinase, pectase and pectinase. J. J. WILLAMAN

The purification of heparin and its chemical and physiological reactions. W. H. HOWELL. Johns Hopkins Univ. *Bull. Johns Hopkins Hosp.* 42, 199-206(1928).—Heparin was purified by the adsorption of impurities by Lloyd's reagent in acid soln. and the pptn. of the active substance by  $Ba(OH)_2$ . The results of 12 reactions indicate that heparin is a glucuronic acid compd. contg., as isolated, probably Ca and  $H_2SO_4$  in the mol. Its reducing properties are seen only after acid hydrolysis, indicating that it is either a paired glucuronate or a condensation product of glucuronic acid. The low C content favors the latter. R. C. WILLSON

The conduct of amylase in the presence of raw starch. GIULIO RADAELLI. Univ. Genoa. *Pathologica* 20, 269-79(1928); *Ber. ges. Physiol. exptl. Pharmacol.* 47, 154.—Salivary amylase combines with starch from rice, corn and potatoes, although the electrolyte is of decisive importance. Cl is the most active, followed by  $NO_3$  and  $PO_4$  in order. The reaction proceeds better in an acid medium than in an alk. one. R. C. WILLSON

Organic chemistry and vital force (VERKADE) 10. The actual reaction at the beginning of decay of flesh (SCHMIDT) 12. Specificity of enzymic cleavage of polypeptides. Experiments with polypeptides containing *dl*-norleucine (ABDERHALDEN, MAYER) 10.

## B—METHODS AND APPARATUS

STANLEY R. BENEDICT

Estimation of sugar in urine by means of fermentation tubes. HANNS WILL. *Apoth. Ztg.* 44, 56-9(1929).—An exptl. study involving the use of 6 different types of fermentation tubes. While the app. of both Einhorn and Fiebig were unsatisfactory, the large Hg saccharometer of Lohnstein gave accurate results. The various factors are discussed which affect the results obtainable with the several types of app. W. O. E.

Concentration of serum through ultrafiltration by means of the centrifuge. A. TÓRN. Kaiser Wilhelm-Inst. Arbeitsphysiologie, Berlin. *Biochem. Z.* 197, 353-6

(1928).—Depending upon the speed of centrifuging, 60–70% of the water can be removed from the serum in 1–1½ hrs. S. MORGULIS

The peroxidase reaction. XXIV. A method of simultaneous application of oxidase and peroxidase reaction on blood leucocytes. KOJI TOKUŌ. *Tōhoku J. Exptl. Med.* 12, 295–300(1929).—Apply a satd. aq. soln. of benzidine (contg. 2 drops of 3% H<sub>2</sub>O<sub>2</sub> per 100 cc.) to an air-dried fresh blood smear for 2 mins.; then add a few drops of a 1% aq. eosin soln. for 5–10 secs. Wash with H<sub>2</sub>O; microscopic examn. shows the peroxidase positive granules in the cytoplasm to be brownish red. Then pour on the same smear the Winkler-Schultze oxidase reagent; after 2 mins. wash and reexam.

B. C. BRUNSTETTER

New method of impregnation with gold. R. ALTSCHUL. *Atti accad. Lincei* [6], 9, 74–6(1929).—By the use of HgBr<sub>2</sub> in combination with AuCl<sub>3</sub>, A. has been able to impregnate the cerebral gray matter as well as the central and peripheral nervous tissues. Formalin is used as a fixator. The sections to be impregnated are washed thoroughly in distd. H<sub>2</sub>O, and dipped in a soln. consisting of (A)1% AuCl<sub>3</sub>, and (B) a satd. soln. of HgBr<sub>2</sub>. Various proportions of A and B have been used as 5:20, 5:40, etc. No developer is necessary, and the sections are passed through 5% Na<sub>2</sub>S<sub>2</sub>O<sub>3</sub>, dried, passed through PhOH soln., and then mounted in Canada balsam.

A. W. CONTIERI

Method for determining the oxygen consumption of rats. U. G. BIJLSMA. Centraal Lab. Volkgezondheid, Utrecht. *Arch. intern. pharmacodynamie* 35, 1–12 (1928).—An app. is described and the exptl. errors are discussed. A large no. of detns. is necessary in order to draw conclusions. *Ibid* 13–29.—Urethan, chloralose and "sominfen" narcotics cause a diminished O<sub>2</sub> consumption in rats, which is not dependent on the narcosis or the concomitant lowering of the temp. but upon an inhibition of the respiratory centers, and, as a consequence of insufficient breathing, upon O<sub>2</sub> want in the tissues. The possibility of a decrease in the vol. of the heart was not excluded.

DAVID DAVIDSON

The determination of lactic acid. THEODORE E. FRIEDEMANN AND ARTHUR I. KENDALL. Northwestern Univ. *J. Biol. Chem.* 82, 23–43(1929).—A procedure for the detn. of lactic acid in biol. material is described and the factors influencing its precision are discussed. The effect of certain interfering substances upon the yield of lactic acid is shown. The lactic acid contents of urine, the blood of man, dog and sheep, and of a 1% peptone-0.3% meat ext. culture medium are also given. A. G.

The physical basis for the electropotentials of the organism and the direct methods of their measurement. REINHOLD FÜRTH. *Kolloidchem. Beihefte* 28, 235–45(1929).—A description of the app. used for the measurement of electro-potential differences in biochem. systems and the physical basis for the existence of such potential differences.

ARTHUR GROLLMAN

Measurements of potential differences. K. UMRATH. *Kolloidchem. Beihefte* 28, 245–51(1929).—A description of the binant and quadrant electrometers and their application to measurement of bioelec. potentials.

ARTHUR GROLLMAN

The preparation of micro-electrodes for potential measurements. JOS. GICKLHORN. *Kolloidchem. Beihefte* 28, 252–8(1929).—Directions are given for the prepn. of micro-electrodes suitable for work on biol. systems.

ARTHUR GROLLMAN

The electrical characteristics of solutions, dyes and biocolloids. REINHOLD FÜRTH. *Kolloidchem. Beihefte* 28, 285–92(1929).—An app. is described for the study of the elec. properties of dyes or other colloidal systems.

ARTHUR GROLLMAN

The analysis of dispersoids by means of a new diffusion apparatus. A. NISTLÉR. *Kolloidchem. Beihefte* 28, 296–313(1929).—A description of the app. and methods of Fürth (C. A. 21, 3513).

ARTHUR GROLLMAN

Methods for the determination of the dielectric constants of biological systems. REINHOLD FÜRTH. *Kolloidchem. Beihefte* 28, 314–22(1929).—A review of the methods used and the results of studies of the dielec. consts. of biol. systems. A. G.

Dielectric constants. REINHOLD FÜRTH. *Kolloidchem. Beihefte* 28, 322–8 (1929).—Dielec. consts. play an important role in elucidating vital phenomena.

ARTHUR GROLLMAN

A simple method of preserving feces containing hookworm eggs. P. A. MAPLESTONE. *Indian J. Med. Research* 16, 675–82(1929).—Two % antiformalin is effective in preserving feces for hookworm egg count.

FRANCES KRASNOW

A comparison of the calculated and determined osmolar concentration of normal serum. The base-binding power of proteins and the determination of total base. DAN. C. DARROW AND ALEXIS F. HARTMANN. Washington Univ. *Am. J. Diseases Children* 37, 51–60(1929).—The concn. of electrolyte in normal blood serum can be

calcd. from a consideration of its compn., and of the degree of dissocn. of the several constituents. It agrees within 92% with the value indicated by measurements of the f. p. depression. The base-binding power of the serum proteins may be more accurately calcd. by the use of sep. formulas for serum albumin and globulin than by the use of the formula proposed by Hastings, *et al.* (*C. A.* 21, 2483). E. R. MAIN

The water content of blood serum. A comparison of the determination of the specific gravity by the falling drop method and by several other methods. HARVEY SPENCER. Harvard Med. School. *Am. J. Diseases Children* 37, 546-52(1929).—The falling drop method for the detn. of the sp. gr. of blood serum appears to be more accurate than methods which involve the detn. of mass, total solid content or plasma protein content by refractometric analysis. Abnormally high values for the sp. gr., total solids and plasma protein may be assocd. with dehydration of the blood plasma. E. R. MAIN

A new colorimetric reaction for protein substances. MICHELE MITOLO. *Boll. soc. ital. biol. sper.* 4, 37-9(1929).—The Eschaich reagent ( $\text{Na}_2\text{S}_2\text{O}_8 + \text{AgNO}_3$ ), used for the identification of phenol, was used for the identification of protein substances contg. the benzene ring. It was more sensitive than the xanthoproteic and equally as sensitive as the Millon tests, except that the yellow color appeared almost immediately with the Eschaich reagent but only after 15-16 hrs. with Millon's when a 0.01% soln. of com. ovalbumin was tested. The test was modified so as to get a zonal reaction. Two solns. were prepd.: (A) 100 mg. ovalbumin + 10 cc. distd.  $\text{H}_2\text{O}$  + 5 drops  $\text{NH}_4\text{OH}$  + 0.10 g.  $\text{Na}_2\text{S}_2\text{O}_8$ ; (B) 10 cc.  $\text{C}_2\text{H}_5\text{OH}$  + 10 drops  $\text{N AgNO}_3$ . 1 cc. of B was poured carefully over 1 cc. of A. At the point of contact of the 2 solns. a yellowish orange ring was formed. The sensitivity of the zonal reaction was equal to the Ehrlich reagent. The Eschaich reagent can, therefore, be used for the detection of protein substances containing the benzene ring and is equal in sensitivity to the Millon or Ehrlich reaction. PETER MASUCCI

A biological ionization chamber. FRANCIS C. WOOD. *Radiology* 12, 461-70(1929).—*Drosophila* eggs are a simple, cheap, convenient and reliable biol. medium for use in checking or standardizing x-ray app. Practical details for their use are given. E. H. QUIMBY

A simple and rapid quantitative test for sugar in urine. WM. G. EXTON, A. R. ROSE AND P. V. WELLS. *Proc. 38th Annual Meeting, Assoc. Life Ins. Med. Directors of Am.* 14, 436-41(1928).—For the detn. of sugar in urine transfer 0.2 cc. to a tube graduated at 10 cc. and add the reagent to this mark. Immerse the tube in boiling water for 5 mins., cool and place the tube in a scopometer (*C. A.* 19, 3390) with the green light filter in place and note the wedge reading at the extinction point. The glucose equiv. is read from a chart. To prep. the reagent [cf. Sumner, *C. A.* 19, 1146] add 6 g.  $\text{C}_6\text{H}_5\text{OH}$  to 200 cc. 4%  $\text{NaOH}$  and then 5 g.  $\text{Na}_2\text{SO}_4$ . Add  $\text{H}_2\text{O}$  to about 500 cc. and then 100 g.  $\text{KNaC}_4\text{H}_4\text{O}_6 \cdot 4\text{H}_2\text{O}$ . Mix, add 7 g. 3,5,2-( $\text{NO}_2$ ) $_3\text{C}_6\text{H}_3(\text{OH})\text{CO}_2\text{H}$  dissolved in 300 cc.  $\text{H}_2\text{O}$  and adjust to 1000 cc. A. R. ROSE

Carbohydrate metabolism. I. Comparison of the microanalytical methods for glucose. RYOSUKE MIYAMA. *Bull. Sci. Fakultato Terkultura, Kjusu Imp. Univ.* 3, 122-31(reprint).—The methods of Benedict, Folin-Wu, Folin, Hagedorn, Shaffer-Hartmann and Bang were used to det. the glucose content of blood, pure glucose solns. and artificial mixed solns. With pure glucose soln. all the methods afforded correct results at their standard concn. but showed more or less error when the concn. was deviated. Benedict's method required the largest quantity of sample and Bang's method the smallest. When blood was used, Bang's method gave the smallest amt. of sugar and Benedict's gave the largest. The order was: Benedict > Folin-Wu > Hagedorn > Folin > Shaffer-Hartmann > Bang. All methods were effected by the addn. of cystine. The addn. of  $\text{Na}_2\text{SO}_4$  gave too high results in Folin-Wu's method and too low result in Bang's method. The other methods were little effected. Conclusion: Hagedorn's method was most reliable. H. M. SOULE

An improved method for titrating sugar in blood and urine. P. J. CAMMIDGE AND H. A. H. HOWARD. *Brit. J. Urol.* 1, 17-32(1929).—For the detn. in urine prep. soln. I by adding 4.948 g.  $\text{H}_3\text{AsO}_3$  and 25 g.  $\text{NaHCO}_3$  to 300 cc. distd.  $\text{H}_2\text{O}$ , boil until dissolved, cool and make up to 1000 cc., and soln. II by dissolving 81 g.  $\text{K citrate}$ , 70 g.  $\text{K}_2\text{CO}_3$ , and 92 g.  $\text{K oxalate}$  in 600 cc. hot  $\text{H}_2\text{O}$ , and adding 25 g.  $\text{CuSO}_4 \cdot 5\text{H}_2\text{O}$  dissolved in 150 cc. warm  $\text{H}_2\text{O}$ , adding 3.2496 g.  $\text{KIO}_4$ ,  $\text{HIO}_3$  to 150 cc.  $\text{H}_2\text{O}$ , boiling until dissolved, making alk. with  $\text{K}_2\text{CO}_3$ , cooling and adding 50 g.  $\text{KI}$ , mixing the solns. and making up to 1000 cc. Add 50 cc.  $\text{H}_2\text{O}$  to 50 cc. soln. II in a 400-cc. flask, boil and add 5 cc. urine. Cool and add 7.5 cc. 30%  $\text{H}_2\text{SO}_4$ . Mix and titrate immediately with soln. I, until the bright blue end point is reached. Subtract the reading from a standard

figure in a preliminary blank detn. and read the glucose equiv. from a table. For blood (A) dissolve 10 g. Na tungstate in 100 cc.  $H_2O$ , (B) dil. 20 cc.  $H_2SO_4$  with 10 cc.  $H_2O$ , (C) to 1 cc. 0.1 N  $H_2AsO_3$  add  $H_2O$  to make 20 cc., (D) dissolve 40 g. crvstd.  $Na_2CO_3$  in 400 cc.  $H_2O$ , add, while stirring, 5 g.  $CuSO_4 \cdot 5H_2O$  and 7.50 g. tartaric acid which had been dissolved in 150 cc. warm  $H_2O$ ; dissolve 0.65 g.  $KIO_3$ ,  $HIO_3$  in 250 cc.  $H_2O$  by heating, neutralize with  $K_2CO_3$  and cool; add 10 g. KI and 18.4 g. K oxalate and then mix in the alk. Cu soln.; cool, make up to 1000 cc. and standardize against soln. C. Prep. protein-free filtrate by adding to 1 cc. blood 7 cc.  $H_2O$  and, when laking is complete, adding 1 vol. each of solns. A and B. Shake, let stand for 5 mins. and filter. Mix 5 cc. of the clear filtrate with 5 cc. soln. D in a narrow test tube. Add a few drops of toluene or benzene and heat the tube in a boiling water bath for 15 mins. Cool immediately in running  $H_2O$  and add 4 cc. soln. B. After 1 min. run in soln. C until the blue end point is reached. Calculation is made as for urine detn. All solns. are stable and can be kept for some time in well-stoppered bottles. R. C. WILLSON

Method of preserving blood for the blood-sugar test. LAX and SZERNAI. *Münch. med Wochschr.* 76, 58-60 (1929).—L. and S. added 1% NaF and 0.1%  $HgCl_2$  to blood and prevented glycolysis and bacterial decompn. for 30 days in the incubator. The process had no influence on the albumin pptn. or sugar reduction. R. C. WILLSON

Determination of reducing sugars by the ferricyanide method (IONESCU-MATIN) 7. Notes of the laboratory. III. New tubes for cataphoresis (VLES) 1.

## C—BACTERIOLOGY

CHARLES B. MORREY

Methods of studying the surfaces of living cells, with especial reference to the relation between the surface properties and the phagocytosis of bacteria. STUART MUDD, MALDUIN LUCKE, MORTON MCCUTCHEON and MAX STRUMIA. *Colloid Symposium Monograph* 6, 131-8 (1928).—This is the first stage of a study to express the mechanism of the action of opsonins and bacteriotropins in physico-chem. terms. Immune sera were made by injecting rabbits with *B. tuberculosis* and other "acid-fast" microorganisms. The bacteria, treated with serial dilns. of normal and immune sera, have been studied in the following reactions: (1) After standing overnight, the degree of pptn or agglutination is read. (2) The serum-bacterial mixts. are strongly centrifuged and the sediments resuspended by shaking until the untreated control tubes show an even suspension; the treated sediments are resuspended in flocculi, increasing in coarseness with their cohesiveness. (3) The treated bacteria are washed and their wetting or interfacial tension properties std. in the interface reaction—before treatment, the microscope shows that they pass readily into the oil at an oil-water interface, whereas after treat-

ment, they resist passing into the oil in proportion to the degree of their interaction with serum. (4) The electrokinetic potential difference between the washed bacteria and their suspending medium is calcd. from detns. in a microcataphoresis cell. (These 4 reactions give a picture of the surface properties.) (5) Meanwhile rabbit leucocytes being used, the phagocytic index of each of the different sera and bacteria was detd. The results show that sera which increase phagocytosis, concomitantly increase the cohesion, decrease the surface potential difference and alter the wetting properties of the bacteria. Conversely, with certain exceptions, when sera have altered the surface properties of bacteria as indicated, they cause the bacteria to be spread upon and engulfed by leucocytes. The exceptions were aged or heated sera, or sera of another species than the leucocytes, and indicate that the requirements for the spreading are more delicate than the physico-chem. reactions used. The results point to the deposition on the bacterial surface of serum components.

JEROME ALEXANDER

**Disinfectant action.** III. HENRY D. CHEESEWORTH AND E. ASHLEY COOPER. *J. Phys. Chem.* 33, 720-8(1929).—Unsatd. compds. in general tend to possess a higher bactericidal and protozoacidal action than the corresponding satd. compds. This is illustrated by the cases of allyl and propyl alcs., unsatd. and satd. fatty acids and phenols and cyclohexanols. A quant. study of the action of allyl alc. on proteins discloses the fact that chem. interaction through the unsatd. grouping does not occur. It is believed that the superiority of unsatd. substances as germicides is associated with their greater physico-chem. capacities to induce pptn. or denaturation in colloid suspension.

FREDERICK G. GERMUTH

**Influence of osmotically active agents on the bacterial cell.** BASJO RAICHEL. *Arch. Protistenk.* 63, 333-61(1928).—Spirilla show plasmolysis with hypertonic solns, the protoplasm breaking into 2-6 unequal portions. With  $H_2O$  and glycerol plasmolysis occurred. Glycerol and urea sometimes produce deformities in the spirilla

F. KRASNOW

**Acid production in media containing carbohydrates by Gram-negative intestinal bacteria.** MACKENZIE DOUGLAS. ROSS INST., London. *J. Trop. Med.* 32, 73-7(1929).—The results are detailed.

F. KRASNOW

**The hydrogen-ion concentration changes in media containing carbohydrates by Gram-negative intestinal bacilli.** MACKENZIE DOUGLAS. ROSS INST., London. *J. Trop. Med.* 32, 89-93(1929).—Results are recorded in detail.

F. KRASNOW

**The chemotaxis of bacteriophage and bacterial products.** PAUL FABRY. Univ. Liège. *Arch. intern. méd. expl.* 4, 409-12(1928).—Lysable bacteria and the sol. products obtained from them appear to exert an attractive force upon their sp. bacteriophages. A filtrate contg. anti-Hiss bacteriophage passes through a Chamberland filter into an emulsion of Hiss bacilli, or into an ext. obtained by grinding the bacilli, but does not pass through the filter into sterile bouillon.

E. R. MAIN

**The behavior of bacteriophage in the presence of nonlysable bacteria.** PAUL FABRY. Univ. Liège. *Arch. intern. méd. expl.* 4, 413-6(1929).—A bacteriophage, in the presence of bacteria which are not lysable by it, but are lysable by other bacteriophages, appears to multiply, although it does not produce visible lysis. A bacteriophage, in the presence of non-lysable bacteria, does not appear to multiply.

E. R. MAIN

**The conditions under which the antibacterial and antitoxic power of bile is manifested.** I. The retardation of lactic fermentation in the presence of bile salts. A. CLEMENTI. *Arch. sci. biol.* (Italy) 13, 211-20(1929).—The object was to det. the effect of bile salts on the intensity of lactic acid fermentation in milk inoculated with lactic acid bacteria. Conclusions: (1) The presence of bile salts causes a retardation of lactose fermentation, and the inhibition of the transformation of caseinogen into casein which takes place during the growth of the organisms in the milk. (2) The increase in H-ion concn., that is a reaction strongly acid to litmus, causes the pptn. of the bile acids and the formation of floccules; this indirectly retards the lactic acid fermentation. II. The growth of *Bacillus coli* in the presence of bile or bile salts. A. CLEMENTI AND A. CASTELLI. *Ibid.* 221-34.—The object was to prove that the inhibiting action of bile or bile salts on the growth of bacteria is due to the formation of insol. bile acids which flocculate and carry down with the ppt. some of the bacteria. The results of the bacterial count showed that in the presence of bile or bile salts there was a marked inhibition in the growth of *B. coli*, if the reaction of the broth became acid owing to the fermentation of dextrose, or is rendered acid artificially by the addn. of lactic acid, but there was no inhibition if the reaction remained alk. The acid reaction of the cultures caused the liberation of bile acids which being insol., pptd., formed floccules, and carried

down the organisms. The inhibition of the growth of bacteria by bile salts is, therefore, not due to any antiseptic action on the part of the bile salts, but is due to the formation of acid in the medium by the fermentation of dextrose or other sugar, and the subsequent flocculation of bile acids. These results also explain the contradictory statements found in literature relative to the action of bile on the growth of bacteria.

PETER MASUCCI

**Experimental studies on the stereoisomeric relations in the dismutation of phenylglyoxal hydrate through various bacteria** (*B. proteus*, *fluorescens*, *pyocyaneum*, *prodigiosum* and *coli*). SHIGERU HAYASHI. Kaiser Wilhelm-Inst. für Biochemie, Berlin-Dahlem. *Biochem. Z.* 206, 223-7(1929).—All contain an enzyme which dismutates phenylglyoxal hydrate quantitatively to mandelic acid which in every instance but one was levorotatory. Reaction  $p_H = 7.0$ . With *B. coli* the dismutation proceeds best at  $p_H = 8.1$ , and a mandelic acid is obtained which contains  $\frac{1}{2}$  to  $\frac{3}{4}$  the dextrorotatory component.

S. MOROGLIS

**Bacteriological study of dysentery in Porto Rico.** OSCAR COSTA MANDRY. Univ. Porto Rico. *Porto Rico Rev. Pub. Health Trop. Med.* 3, 259-66(1928).—Though "diarrhea and enteritis" cause more deaths in Porto Rico than any other group of diseases, organisms of the dysentery group were absent in the stools of 71 cases of acute diarrhea. In 6 cases the Flexner type of dysentery bacillus was found. The presence of other organisms, *e. g.*, *B. paratyphosus* B, *B. enteritidis* and *B. suispestifer* was revealed in diarrheal cases as well as in the controls.

G. SCHWOCH

**The action of mercurochrome and tincture of iodine in skin disinfection.** W. W. SCOTT, J. H. HILL AND M. G. ELLIS. Johns Hopkins Univ. *J. Am. Med. Assocn.* 92, 111-16(1929).—There are extreme exptl. conditions under which neither 7% tinct. I nor the alc.-acetone-H<sub>2</sub>O 2% soln. of mercurochrome will sterilize. Both substances are equally effective in the sterilization of uncleansed human skin, the differences being within the limits of exptl. error.

## D—BOTANY

THOMAS G. PHILLIPS

**Anaerobic respiration of aspergilli.** HIROSHI TAMIYA AND YASUSABURO MIWA. Univ. of Tokyo. *Z. Botan.* 21, 417-32(1929).—The various species of aspergilli may be arranged in a series showing varying degrees of ability to bring about alc. fermentation. *A. clavatus* approaches yeast in its fermentative power. *A. glaucus*, on the other hand, shows little activity in this respect. Fermentative power of peptone cultures of various aspergilli is only  $\frac{1}{4}$  to  $\frac{1}{2}$  that of sugar cultures. Younger mycelia are always richer in ymase than the older. A special app. for measuring CO<sub>2</sub> developed during fermentation is described.

R. C. BURRELL

**The origin of chlorophyll and its relation to the blood pigment.** I. KURT NOACK AND WILHELM KIESSLING. Univ. Erlangen. *Z. physiol. Chem.* 182, 13-49(1929).—The material which furnished the basis for this investigation was the hitherto chemically unknown *protochlorophyll* which may be demonstrated spectroscopically in leaves that have developed in the dark. For preparative purposes it is best obtained from the inner seed coat of the Cucurbitaceae. Protochlorophyll is closely related to chlorophyll. It contains Mg and the typical phytol and Me ester groups. By treatment with acid it is converted into a Mg-free pigment for which the name *protopheophytin* is proposed. By means of the Grignard reaction ( $p\text{-Me}_2\text{NC}_6\text{H}_4\text{MgI}$ ) it can be converted back to the original Mg complex. Protochlorophyll represents a reduction stage of chlorophyll. Comparatively mild treatment of pheophytin *a* and *b* in acid soln. with Fe gives protopheophytin. There is no evidence thus far, however, of the existence of 2 modifications either of the natural protopheophytin or of protochlorophyll corresponding to chlorophyll *a* and *b*. The reduced stage appears to lose the property of allomerization. By reduction with HI pheophytin yields a pigment almost identical with the phylloerythrin from ox gall. Protopheophytin is very closely related to phylloerythrin, which is an anhydride of a carboxylic acid, and which, after introduction of Mg by the Grignard reaction, yields a green substance almost identical spectroscopically with protochlorophyll. Both the synthetic protopheophytin and the phylloerythrin can be split up into the same carboxylic acid which has a strong tendency toward anhydride formation. The natural protopheophytin could thus far be split into the free acid (as Ca salt) only

through the anhydro compd. The tendency here toward anhydride formation by the free acid seems to be still greater. The carboxylic acids obtained from phyloerythrin and synthetic protopheophytin are spectrally identical as are also the 2 Me esters prepd. therefrom. Their spectrum belongs to another type than that of the original substances. However, the free carboxylic acid of phyloerythrin on standing rearranges into a less acidic substance of the spectral type of the mother substance. From natural and synthetic protopheophytin, as also from phyloerythrin, spectrally identical anhydro compds. of the 2nd type were obtained which easily revert to the spectral type of the original substances. The absorption spectrum of the carboxylic acid obtained from protopheophytin and phyloerythrin coincides to a great extent with those of the blood pigment porphyrins. This acid, as also its Me ester, on illumination becomes transformed into a chlorophyll-green substance showing the red band typical of chlorophyll. This process, which occurs with the acid from protopheophytin as well as with that from the animal pigment phyloerythrin, may be regarded as a photooxidation.

A. W. DOX

New observations on the metabolism of *Ustilina vulgaris* L. H. WÜNSCHEN-DORFF AND CH. KILLIAN. *Compt. rend.* 188, 1124-6(1929); cf. *C. A.* 23, 635.—Eight lab. expts. with this fungus where the incubation temp. was controlled at 25° and the evolved gases were analyzed showed that the wt. of  $\text{NH}_3$  formed is directly proportional to the dry wt. of the fungus mycelium. As growth proceeds the acidity of the nutrient soln. decreases. The % of N fixed (in its own mycelium) is practically const at 6.5%. Where non-optimal growth conditions are present, i. e., where the peptone concn. in the medium is below 0.3% or above 3%, the results are very different and the fungus makes only a submerged growth.

C. R. FELLERS

Glutelins. V. The glutelins of rye (*Secale cereale*), and of barley (*Hordeum vulgare*). FRANK A. CSONKA AND D. BREESE JONES. U. S. Dept. Agr. *J. Biol. Chem.* 82, 17-21(1929); cf. *C. A.* 22, 3193.—Rye contains one glutelin which seps. from a 0.2% NaOH soln. by addn. of  $(\text{NH}_4)_2\text{SO}_4$  to 3% satn. Barley contains 2 glutelins which sep. from the alk. medium at 1 to 2%, and at 18%, resp., of satn. with  $(\text{NH}_4)_2\text{SO}_4$ . The elementary compn. of the rye glutelin and that of the  $\alpha$ -glutelin of barley were detd. The cystine, arginine, histidine and lysine contents of the glutelin of rye are 2.56, 7.07, 2.75 and 5.39%, resp., and the  $\alpha$ -glutelin of barley, 3.10, 5.59, 1.09 and 2.88%, resp. The isoelec. point of rye glutelin is  $p_H$  6.2; and of the  $\alpha$ -glutelin of barley, 6.4. A. G.

Vital staining as a general method of botanical investigation. J. PEKAREK. *Kolloidchem. Beihefte* 28, 280-5(1929).—Vital staining is a much more useful aid in botanical investigation than fixation and staining of the dead tissue.

ARTHUR GROLLMAN

Effect of the hydrogen-ion concentration on the reaction of ammonium salts in a nutrient solution. WALTER MEVIUS. *Planta Abt. E Z. wiss. Biol.* 6, 379-455(1928).—Corn seedlings and cuttings of *Tradescantia fluminensis* produced normal plants in solns. contg.  $\text{NH}_4$  salts of strong acids as a source of N, provided the reaction of the soln. was acid. Keeping the soln. neutral or alk. by adding  $\text{CaCO}_3$  caused severe injury to the plants.  $\text{NaNO}_3$ , on the contrary, was injurious at acid but not at neutral or alk.  $p_H$  values. The  $p_H$  value of the soln. was not a limiting factor for  $\text{NaNO}_3$ . Since an acid reaction results from the preferential absorption of  $\text{NH}_4$  ions in the case of corn, it is believed that the injury in an alk. soln. is due to the nature of the  $\text{NH}_4$  radical. The N requirement of the plant is believed to be an important factor in detg. the degree and nature of preferential absorption and hence the reaction of the soln. Changing the soln. frequently was usually found to be detrimental. An extensive review is given of the theories relating to preferential absorption and the mechanism causing injury.

A. E. HITCHCOCK

Contributions to the study of spike disease of sandal (*Santalum album*, Linn.) IV. Composition of healthy and spiked Sandal stems. D. A. RAMA RAO AND M. SREENIVASAYA. *J. Indian Inst. Sci.* 11A, 241-3(1928).—Sandal stems 0.20 to 0.50 cm. in diam. from diseased and healthy trees were analyzed. Diseased stems contain less ash, Ca and K but more N, P and starch. The diseased and healthy stems show similar seasonal variations in compn. V. Transmission of spike by budding. M. SREENIVASAYA AND G. GOPALASWAMI NAIDU. *Ibid* 244-7.—Buds derived from spiked stems were budded successfully on to healthy stocks and after 131 days the stock showed the disease.

H. R. KRAYBILL

The possibility of administering carbon to the leaves of plants. LUIGI MONTE-MARTINI. *Ann. accad. agr. Torino* 70, 3-15(1927).—In an endeavor to ascertain whether extremely finely divided carbon can increase the  $\text{CO}_2$  utilized in chlorophyll assimilation 163 expts. were conducted with "vegetina" (an impalpable powder having carbon as a base) and 92 with pulverized wood charcoal. Plants with pinnate or lobate leaves were

treated, such as kidney bean, potato, mulberry, *Pawlonia*, rose, fig, *Sophora*, tomato, *Ricinus*, horse chestnut, ash, *Glycine*, *Begonia*, *Arabis*, raspberry, etc. Favorable results, in which the increase of dry weight per unit of surface in the treated leaves exceeded that of the untreated leaves, predominated slightly. This predominance was less pronounced with the charcoal. The tests, however, do not permit a definite conclusion and further expts. are necessary.

ALBERT R. MERZ

The structure-forming substances in cabbages. II. HANS PRINGSHEIM AND CHARLES R. FORDYCE. *Ber.* 62B, 831-2(1929).—The structural substance in red cabbage and cauliflower is identical with that in white cabbage, namely a *polyhexosan*. It gives with  $\text{ZnCl}_2$  and I the same reaction as cellulose. The dry substance is hard to be dissolved, but after imbibition of  $\text{H}_2\text{O}$  it is dissolved in a soln. of 15 g.  $\text{Cu}(\text{OH})_2$  in 1000 cc.  $\text{NH}_3$  of 25% and 100 cc.  $\text{NaOH}$  of 8%. The soln. of the triacetate in  $\text{CHCl}_3$  has  $[\alpha] = 0$ , compared with 23 for cellulose. The soln. in an ammoniacal  $\text{Cu}$  soln. with 7.2 mol.  $\text{Cu}$  has a lower  $[\alpha]$  than cellulose. The sugars formed by hydrolysis with  $\text{HCl}$  could not be identified, as decompn. occurs. The x-ray diagram of the leaves is the same as with cellulose.

A. E. MEYER

The vital accumulation of dyestuffs. JOS. GICKLHORN. *Kolloidchem. Beihefte* 28, 367-82(1929).—In vital staining, 3 phases must be distinguished: absorption, accumulation and distribution of the dyestuff. Expts. were made with the epidermis of the fruit of *Symphoricarpos racemosus* L. At low osmotic pressure of the cell fluid globules are present, which absorb the dyestuff. Neutral red and naphthalene blue were used. If the cells are subjected to plasmolysis, the globules are dissolved and the dyestuff is uniformly distributed through the cell fluid. The globules consist of a viscous liquid. Later a colored membrane is formed that includes a colorless liquid. The membrane gives protein reaction. By the access of the dyestuff the equil. in the cell fluid is disturbed and a mixt. of protein and lipoids pptd. The same phenomenon was observed in 120 plants. In the cells of the epidermis of the base of the leaf of *Iris germanica*, *florentina* and *flavescens*, the globules are always visible as glittering drops. All cells especially suitable for the observation contained much  $\text{MgNH}_4\text{PO}_4$ . If cells from scales of bulbs are subjected to plasmolysis against a soln. of  $\text{KNO}_3$  contg.  $\text{Cu}$ , the cell fluid is pressed out of the protoplasm. At the polarization microscope, a concentric arrangement in layers was observed, due to double refraction of crystals of  $\text{Cu}$  salts of fatty acids. Concerning vital staining, there is no fundamental difference between plant and animal cell. The latter contains cell fluid, where the dyestuff is absorbed, while in the former the protoplasm first seps. fine drops of the protein lipid mixt. and so forms the granulation. The quantity of granulation depends on the amt. of that mixt. present in the cell. The accumulation of the dyestuff is not a measure of the permeability of the cell; neither does it give indications as to electrostatic charges in the plasma.

A. E. MEYER

An indigenous manna. E. HERRERO DUCLOUX. *Rev. facultad cienc. quim.* (Univ. La Plata) 5, Pt.1, 73-6(1928).—The manna is produced on eucalyptus trees (*E. viminalis*) by the sting of an insect; it is a white substance, of sweet taste and neutral reaction, partly sol. in  $\text{H}_2\text{O}$ ,  $\text{CHCl}_3$ ,  $\text{MeOH}$  and  $\text{EtOH}$ . It contains:  $\text{H}_2\text{O}$  13.922%, ash 0.600%, waxes 0.200, insol. in  $\text{H}_2\text{O}$  0.725%, gums 1.50%, arabinose 2.90, raffinose 54.00, dextrose 15.50, sucrose 25.30.

A. E. MEYER

Dynamics and energetics of carbon dioxide assimilation. JULIUS STOKLASA, J. PENKAVA AND JAZMILA PETROVA. *Ernähr. Pflanze* 25, 97-105(1929).—There is reviewed here much of the exptl. evidence obtained by S. and his coworkers in support of the idea that the action of *K* in plant growth is due to its radioactivity. L. P. MILLER

Studies of wood-destroying fungi. I. *Polyporus hispidus* (Fries). F. J. NUTMAN. Dept. Sci. Ind. Research, Forest Products Lab., England. *Ann. Appl. Biol.* 16, 40-64(1929).—The following enzymes were found in the mycelium: emulsin, diastase, invertase, ligninase, hemicellulase, oxidase and catalase. The list is probably not exhaustive. A method for the demonstration of ligninase is evolved from a modification of Czapek's "hadromal" reaction. Other biol. data are given. C. H. RICHARDSON

The quantitative determination of chlorophyll. F. M. SCHERTZ. *Plant Physiol.* 3, 323-34(1928).—The more important methods for detg. chlorophyll are reviewed. Colorimetric and spectrometric methods of detg. chlorophyll are described, graphs given and results are compared. The former method is more accurate at chlorophyll concns. of about 0.05 g. per l., the latter at concns. of 0.10-0.15 g. per l. The stability of *K* chlorophyll as a standard is discussed. F. M. SCHERTZ

Studies on solute translocation in plants. Experiments indicating that translocation is dependent on the activity of living cells. OTIS F. CURTIS. Cornell Univ. *Am. J. Botany* 16, 154-68(1929).—When the petioles of bean leaves are chilled to be-

tween about 1° and 4-6°, the removal of carbohydrates from the leaf blades is stopped or greatly retarded. The temps. causing a check in translocation approximate those causing a cessation of protoplasmic streaming and it seems that this streaming protoplasm carries the solutes through the phloem. The available data indicate that the rate of translocation is not much influenced as the temp. is lowered from 25° to around 6-8° even though streaming is retarded as the temp. is lowered. Translocation is, however, markedly checked or stopped at a temp. between 1° and about 4° to 6°. The effect of chilling seems to become evident only at a rather definite temp. Chilling to temps. around 4-6° or below also interferes with the upward movement of inorganic nutrients. The removal of carbohydrates from the leaves of beans seems not to be interfered with appreciably by coating the petioles with melted wax. This is probably due to effective aeration through the petiolar cavity. On the other hand, when the petioles are enclosed in tubes containing N under slight pressure translocation is checked. The evidence indicates that living cells take an active part in both upward and downward solute translocation. It also supports the hypothesis, suggested by ringing and xylem-cutting expts., that upward movement of solute takes place chiefly through the phloem. J. J. SKINNER

The chemical composition of *Andropogon virginicus* and *Danthonia spicata* at successive growth stages. R. B. DUSTMAN AND L. C. SHRIVER. West Virginia Agr. Expt. Sta. *J. Am. Soc. Agron.* 21, 561-7(1929).—The early growth of both grasses is characterized by a relatively high protein and low fiber content compared to the later growth stages. Tables show the % of crude protein, crude fiber, N-free ext., ether ext. and ash. E. F. SNYDER

Chemical relationship between scion and stock in citrus. A. R. C. HAAS AND F. F. HALMA. Citrus Expt. Sta., Riverside, Calif. *Plant Physiology* 4, 113-21(1929); cf. *C. A.* 22, 4149; 23, 409.—Ash, total and water-sol. Ca, total and water-sol. Mg were detd. in Mar. and Aug. in the trunk bark of most of the important varieties of Calif. citrus which represented various commonly occurring combinations of scion and stock. The differences in the Ca content in the leaves of orange and lemon noted previously (*C. A.* 22, 2390) do not exist in the trunk bark, but differences in sol. Mg do exist. Sol. Mg is lowest in the lemon and sour orange and highest in the sweet orange and grapefruit. The values found in the bark of the stock varied according to the scion variety with which it is combined. It is suggested that the growth rate between lemon and sweet orange or grapefruit may play an important role in detg. the influence of scion on stock, for the leaves of the former draw more heavily on the Mg supply than those of the latter. WALTER THOMAS

Seasonal variation of the chloroplast pigments in several plants on the Mall at Washington, D. C. F. M. SCHERTZ. U. S. Dept. Agr. *Plant Physiology* 4, 135-9 (1929).—Detns. of carotin, xanthophyll, total carotinoids and chlorophyll ( $\alpha + \beta$ ) made at intervals during the growing season on both young and old leaves of 3 trees and 2 shrubs showed considerable variation in the amts. of these pigments (*C. A.* 8, 3565). Attempts to correlate the effect of temp., sunshine and rain with the quantity of pigment present were not successful. S. points out the necessity for care in sampling and the danger of general conclusions from the results of only one season's work. W. T.

Plant pigments. IX. Crocetin and lycopin (KARRER, *et al.*) 10. Plant pigments (KARRER) 10.

PHILIP B. HAWK

Studies on the effect of muscular exercise in beriberi. I. The influence of muscular exercise upon the gas and carbohydrate metabolism (resynthesis of lactic acid, acidosis and the entity of fatigue in beriberi). ROKURO INAWASHIRO AND ENAJI HAYASAKA. *Tôhoku J. Exptl. Med.* 12, 1-28(1928).—In 10 cases of beriberi, muscular exercise produced the following effects: (1) the resynthesis of lactic acid is retarded; (2) the decrease of O<sub>2</sub> consumption and respiratory vol. to initial values is much prolonged; (3) the respiratory quotient decreases from a max. nearly equal to the controls to levels far below initial values to which it slowly returns; (4) acidosis is increased; (5) blood sugar is increased. These changes were also found after exercise in a case of exptl. human B-avitaminosis. II. The influence of muscular exercise on the circulatory apparatus, with special reference to its dynamic function as well as

the utilization and supply of oxygen in beriberi (the cause of the hypertrophy and dilatation of the heart in beriberi and the relaxation of the peripheral blood vessels). ENAJI HAYASAKA AND ROKURO INAWASHIRO. *Ibid* 29-61.—Muscular exercise produced in a case of human exptl. B-avitaminosis the same circulatory derangements, though to a less marked degree, that occur in beriberi. The blood flow in beriberi, higher in rest than normal, is increased after exercise; this is attributed to the relaxation of peripheral blood vessels, which in turn seems to be related to paralysis of vasomotor nerve endings, to acidosis and to an increased output of adrenaline or adrenaline-like substances. As a result of this increased blood flow, the heart is excessively worked which, together with the associated paralysis of the respiratory muscles, causes hypertrophy of the right heart. This dilatation of the heart is aggravated by acidosis. Author's conclusion: Since muscular exercise increases blood flow and acidosis markedly in beriberi, it will accelerate the hypertrophy and dilatation of the heart. B. C. B.

Study of wheat bread and of brewer's and baker's yeasts from the point of view of their vitamin B content, and an attempt at the preparation of a bread containing sufficient vitamins. N. V. VESELKIN, O. P. YAROSLAVTZEVA, G. L. SELIBER AND G. A. BOVSHIK. *Bull. Inst. Lesshaft* 12, 87-96(1927); *Biol. Abstracts* 2, 85-6.—Expts. on 4 pigeons, using white bread with varying amts. of baker's yeast and with addns. of brewer's yeast dried at 40°, showed that 0.2 g. of dried brewer's yeast fed daily separately with white bread *ad lib.* provides enough vitamin B to maintain weight and to prevent polyneuritis. Since 0.5 g. brewer's yeast was needed to provide sufficient vitamin B with a vitamin B-free basal diet, it was concluded that white bread contg. 0.5% baker's yeast provided about 1/2 the vitamin B necessary to maintain weight. Attempts to increase this vitamin content of bread by addns. of baker's yeast up to 6% of the total weight were unsuccessful, but addns. of dried brewer's yeast to the dough produced a bread on which the pigeons maintained their wts. const. It is concluded that by addn. of dried brewer's yeast to the dough white bread can be made adequate for human use without change in taste. H. L. D.

What is involved in testing a food for vitamin D? E. J. QUINN. *Columbia Univ. Food Industries* 1, 249-51(1929).—A review of curative and preventive methods for vitamin D assay, using x-ray, histological and chem. criteria. C. R. F.

Nutritional leg-weakness in poultry. R. J. MILLER, R. A. DUTCHER AND H. C. KNADEL. *Poultry Sci.* 8, 113(1929).—Line-tests and bone-ash detns. in large groups of white leghorn chicks on a rachitogenic diet indicated that irradiation for 15 mins. daily with the quartz Hg vapor lamp and with the blue-flame C arc lamp, and by means of sunlight transmitted through Vitaglass and Celo-glass, produced growth response and skeletal development comparable with the results obtained with Newfoundland or Norwegian cod-liver oils. (2 lbs. per 100 lbs. of ration.) C. R. F.

Fish oils as sources of vitamin D for poultry. V. S. ASMUNDSON, W. JOHN ALARDYCE AND JACOB BIELY. *Univ. Brit. Columbia, Vancouver. Sci. Agr.* 9, 594-8(1929).—Standard cod-liver oil contg. 1600 units of vitamin D was compared with pilchard and dog fish-liver oil. Two-day chicks were fed a standard ration, supplemented with oil, until 46-49 days old. The ration consisted of 97 lbs. yellow corn, 2 lbs. CaCO<sub>3</sub>, 1 lb. NaCl and 10-15 lbs. dried skimmed milk. Both "leg weakness" and ash analyses of the tibia were used in judging the vitamin D deficiency. Five series of expts. showed that if the ash content due to 2% cod-liver oil was used as 100, then 2% dog fish-liver oil was valued at 78.5, pilchard oil approx. 86 and control (no oil) 72.3. The temp. at which the dog fish-liver oil was rendered had no effect on its vitamin D potency. Like , 4% of the dog fish liver was no better than 2%. Both pilchard and dog fish-liver oils are variable as to vitamin D potency and in no case are as potent as either com. or medicinal cod-liver oils. C. R. F.

Nutrition and reproduction. III. G. GRIJNS, K. DE HAAN AND J. A. VAN DER LOEFF. *Verslag Akad. Wetenschappen Amsterdam* 37, 540-52(1926); cf. C. A. 20, 3488. Results of a large no. of feeding expts. with different rations are given and tabulated in detail as to the effect on the reproduction of rats. For the production of fertile spermatozoa, as well as the normal reproductivity of the females, there must be present sp. fertility factors in the food, similar to the other vitamins. A special factor is also necessary for a good lactation, probably consisting of an albumin producer. J. C. JURRIJENS

The milk feeding of children. E. BLANCHE STERLING. U. S. Pub. Health Serv. U. S. *Pub. Health Repts.* 44, 957-64(1929).—S. discusses breast milk, cow milk and goat milk. J. A. KENNEDY

The association of bowel disease with vitamin-C deficiency. F. P. MACKIE AND G. D. CHITRE. *Haffkine Inst. Indian J. Med. Research* 16, 77-91(1928).—Monkeys

fed on a diet deficient in or lacking vitamin C become debilitated and anemic, lose weight rapidly and generally suffer from terminal dysentery which ends in death. Administration of orange juice causes a return to health provided the scurvy conditions are not too far advanced. The morbid histology of the intestine suggests degenerative changes due to a toxin.

The interpretation of nutritional experiments. CLIVE NEWCOMB. Pasteur Inst., Coonoor. *Indian J. Med. Research* 16, 537-43(1928).—A statistical discussion of the variations in the wts. of rats and the coefficients of these variations are given.

Calcium and phosphorus metabolism in artificially fed infants. I. Influence of cod-liver oil and irradiated milk. AMY L. DANIELS, GENEVIEVE STEARNS and MARY K. HURTON. State Univ. of Iowa. *Am. J. Diseases Children* 37, 296-310(1929).—The marked differences exhibited by artificially fed infants, in the retention of Ca and P, and in the relative proportions of P excreted in the urine and feces may be a means of detecting early metabolic changes which may result in rickets. Ca and P should be retained in the proportion of 2 parts of Ca to 1 part of P for the normal, optimum development of infants under 1 yr. of age. The retention of these elements appears to be influenced by the antirachitic potency of the foods, as is shown by the following Ca-P retention ratios observed after the feeding of the various mixtures: pasteurized milk, 0.5; boiled milk, 1.2; pasteurized milk and cod-liver oil, 0.8 to 1; boiled milk and cod-liver oil, 1.2 to 1.48; milk with irradiated olive oil, 1.48; and irradiated milk, 2.0.

A brief discussion of vitamins A, B, C and D. D. H. COOK and TRINITA RIVERA. Univ. Porto Rico. *Porto Rico Rev. Pub. Health Trop. Med.* 3, 267-78(1928). G. S.

Numbers of trichomonads in rats on diets of different protein content in relation to the  $pH$  and bacteria in the cecum. HERBERT L. RATCLIFFE. *Am. J. Hyg.* 8, 910-34(1928).—Protein diets influence the number of *Trichomonas muris* to be found in the rat cecum, chiefly through the influence exerted upon the proteolytic anaerobes of the intestine. High protein (casein) diets favor the multiplication of anaerobes and thus tend to restrict the development of trichomonads. While diet modifies the  $pH$ , the latter is of no direct effect on the intestinal flora.

Effect of adrenaline with an excessive amount of fat in the diet: Physiology of the heart and formation of carbohydrate from fat. GUSTAV STÖRRING. Univ. Bonn. *Arch. ges. Physiol.* (Pflüger's) 221, 282-95(1928).—The data presented indicate that adrenaline favors the transformation of fat into carbohydrate.

Phosphatemia in the normal and rachitic organism. JOSEF WARKANY. *Z. Kinderheilk.* 46, 1-12(1928).—When the normal child is given by mouth 0.5 g. of  $Na_2HPO_4$  per kg. of body wt. the increase in inorg. P in the blood is as much as 3.4 mg. %, while the rachitic child reacts with an increase of but 0.4 mg. %. If, however, the rachitic child is given vigantol, the administration of  $Na_2HPO_4$  results in a phosphatemia as great as that shown by the normal child. II. *Ibid* 716-22.—The administration of vitamin D modifies the phosphatemia curve in the rabbit. It is suggested that this fact be used to test the potency of antirachitic preps.

Resorption and retention of egg albumin (nitrogen, phosphorus, sulfur, etc.) by infants. ARMAS RUOTSALINEN. *Z. Kinderheilk.* 46, 370-83.—Infants given egg albumin show a positive balance as regards mineral substances such as P and S, as well as nitrogenous substances and fats.

Disturbances of phosphate metabolism in rickets. II. Excretion of endogenous phosphate. WALTER HEYMANN. *Z. Kinderheilk.* 46, 575-83.—The excretion, by way of the urine, of endogenous phosphate by rachitic children is, per kg. of body wt., about twice that of non-rachitic children, although there is little, if any, difference in excretion through the intestine. III. Phosphatemia in rachitic and non-rachitic children after the parenteral administration of organic and inorganic phosphate. *Ibid* 584-7.—The rachitic and non-rachitic children show the same differences in P in the blood, regardless of whether the P is given by mouth or by injection.

The biochemistry of the carotinoids. BETH v. EULER, HANS v. EULER and P. KARRER. *Helv. Chim. Acta* 12, 278-85(1929).—A study of the growth effect of vitamin A on rats using various carotinoids as sources of the vitamin. Daily doses of 0.01 mg. carotin per rat gave very definite positive growth effects contrary to results of Steenbock, et al. (*C. A.* 16, 1797, 2152, 2166). Dihydroxy- $\alpha$ -crocetin (irradiated peanut oil), 0.015 mg. per day in conjunction with vitamin D, had a surprisingly high growth effect. Lycopin, bixin and capsanthin had no effect. Results were uncertain with norbixin and dihydroxynorbixin. Expts. to correlate the biological results with tests involving measurement of the blue color developed upon addn. of  $SbCl_5$  to a  $CHCl_3$

soln. of the vitamin A food were negative. It was found that all carotinoids and various starches give the  $\text{SbCl}_5$  reaction while vitamin A effect is by no means a general property of naturally occurring carotinoids. Livers from normal rats fed on a mixed diet were found to have a carotinoid content of 25-35 Lovibond units per g. of fresh liver while two carotin-fed rats showed 19 and 29 units, resp. M. H. SOULE

WALKHOFF, OTTO. Die Vitamine in ihrer Bedeutung für die Entwicklung, Struktur und Widerstandsfähigkeit der Zähne gegen Erkrankungen. Berlin: H. Meusser. 100 pp. Linen, M. 13.50.

## F—PHYSIOLOGY

E. K. MARSHALL, JR.

Heat of combustion of living muscle. H. RYCHLEWSKA. *Acta Biol. Exp. Warsaw* 1, No. 2, 1-6(1928).—The heat of combustion of 1 g. of fresh frog gastrocnemius muscle is 1076.5 g.-cal.; after drying, this value rises to 1094.4 g.-cal. The heat of imbibition of muscle is 12.51 g.-cal. per g. of dry substance. The processes taking place during the drying of muscle must be of an endothermic nature. B. C. A.

Physical chemistry of the epidermis. H. SCHADE AND A. MARCHIONINI. *Arch. Dermatol. u. Syphilis* 154, 690-716(1928); cf. *C. A.* 22, 1183.—The  $p_H$  of the epidermis is between 1.78 and 5.17, the av. value being 3.78; the values vary at different points. Perspiration is assoc. with an increase of acidity; wounding or restricted evapn. is attended by an alk. reaction. B. C. A.

Dehydrogenation processes with choroid membranes of albino and pigmented animals. A. CUCCHIA. *Arch. farm. sper.* 45, 67-74(1928).—Contrary to expectation on the oxidation theory of albinism and pigmentation, there is no distinct difference between the rates of reduction of *m*-dinitrobenzene by the choroid membranes of eyes of albino and of pigmented rabbits. B. C. A.

Biochemistry of mixed human saliva. I. Dextrose content. D. ENTIN AND A. A. SCHMIDT. *Deut. Monatsschr. Zahnheilk.* 1927, 710-2.—The Hagedorn-Jensen method is not applicable to saliva. Dextrose and fermenting substances are absent from fasting mixed human saliva. The quantity of substances which reduce thiocyanate (av. 9.7 mg. %) is fairly const. for the individual. B. C. A.

Influence of application of cold or heat to the dog body upon the adrenaline output rate. SHIDZUKA SAITO. *Tohoku J. Exptl. Med.* 11, 544-67(1928).—Cooling non-anesthetized dogs caused no increase in the rate of adrenaline discharge. A slight increase in body temp. did not affect the adrenaline secretion rate, which, however, increased to 7 times the rest period rate when the anal. temp. exceeded  $41^\circ$ . There was a fairly long after-action. B. C. BRUNSTETTER

The presence of adrenaline in the suprarenal bodies in human and bovine fetuses. SHIDZUKA SAITO. *Tohoku J. Exptl. Med.* 12, 254-62(1929).—The suprarenal glands of ox fetuses (4 to 8 months) have as much adrenaline as the adult glands calcd. on a basis of gland wt. Two ox fetuses (13.5 cm. and 15.5 cm., resp.) gave positive results by the rabbit intestine segment method. The left suprarenal of a 5-month human fetus (living briefly after abortion) contained, in mg. per g. of gland, 0.82 by Folin's method, and an av. of 0.02 by 4 closely agreeing biol. methods; a 12 weeks old human fetus gave negative results. The left suprarenal gland of a still-born full-term human fetus contained 2.45 mg. adrenaline by Folin's method (various biological assays were negative); an ext. of the right gland tested negative by Suto's colorimetric method. B. C. BRUNSTETTER

Seasonal variations in the calcium content of the blood serum of the young white rat. A. T. CAMERON AND KATHLEEN R. TURNER. *Univ. Manitoba. Trans. Roy. Soc. Can.* 22, Sect. V, 135-44(1928).—The serum-Ca of the normal adult white rat is reasonably const. (10-11 mg. per 100 cc. serum) throughout the year and the sexes exhibit no difference. The younger the rat the more its serum Ca seems susceptible to influences depressing it below normal (to 6 or 7 mg. per 100 cc.), so that in av. animals about 40 g. in wt. values usually considered normal are only maintained at the height of summer. The chief controlling factor seems to be the solar ultra-violet radiation producing its effect through variations in vitamin D in the food fed the rat. In expts. in which young white rats are employed unless special dietary or other precautions are taken fluctuations in blood Ca are to be expected as normal occurrences. A. T. CAMERON

An attempt to concentrate the active principle of the adrenal cortex. A. T. CAMERON AND F. D. WHITE. *Univ. Manitoba. Trans. Roy. Soc. Can.* 22, Sect. V, 145-9(1928).—Using the enhancement in growth rate of young white rats as test, evidence

is adduced that the active principle of the adrenal cortex passes into the hydrolyzate during hydrolysis with 0.1 N HCl (confirming Kühl, *C. A.* 21, 2813). A. T. C.

The removal of glycogen from living muscle. J. M. HERSHEY AND M. D. ORR. Univ. Toronto. *Trans. Roy. Soc. Can.* 22, Sect. V, 151-7(1928).—Neither starvation and exercise, nor starvation, exercise and shivering removed glycogen completely from the body of the white rat. After strychnine convulsions lasting for varying periods some glycogen still remains in the muscles and liver of the rabbit. A. T. CAMERON

The effect of removal of the liver on the alkaline reserve and the lactic acid content of the blood. L. G. KILBORN, S. SOSKIN AND J. C. THOMAS. Univ. Toronto. *Trans. Roy. Soc. Can.* 22, Sect. V, 159-61(1928).—Expts. with normal, eviscerated, and hepatectomized dogs show a close relationship between the rise in the lactic acid content and the fall in CO<sub>2</sub> capacity of the blood. They cast considerable doubt upon the validity of the respiratory quotient as an index of the type of metabolism proceeding within the organism following such exptl. procedure as evisceration, hepatectomy, or nephrectomy. A. T. CAMERON

The isolation of methyl-hydantoin from an extract of ox testes. J. B. COLLIP AND R. SANDIN. Univ. Alberta. *Trans. Roy. Soc. Can.* 22, Sect. V, 185-6(1928).—In the process of prepg. tissue exts. contg. pressor substances cryst. deposits were frequently obtained in the final stages. That from ox testes on purification and analysis was found to be  $\beta$ -methylhydantoin, the yield by the method used being about 5 g. per 40 kg. of fresh glands. Recrystn. was carried out very satisfactorily with Ac<sub>2</sub>O. A. T. CAMERON

Muscle glycogen in mammals. MARGARET E. MCKAY. Univ. Toronto. *Trans. Roy. Soc. Can.* 22, Sect. V, 329-33(1928).—Expts. on rabbits and cats show that glycogen does not fall rapidly after death, if the tissue is intact. The rate of disappearance is comparatively fast in the sartorius and slowest in the gastrocnemius, which shows no fall after 2 hrs. The glycogen of crushed rabbit muscle practically disappears 15 minutes after the injury. Possibility of restoration of muscle glycogen of which the supply has been depleted by stimulation has been tested in decapitate and decerebrate cats. There is no evidence of any recovery of muscle glycogen after a stimulation period of more than 5 mins. With shorter periods (1 or 2 mins.) there is only some evidence of slight recovery in the gastrocnemius. Causes of this failure in the decerebrate animal are discussed. A. T. CAMERON

Cholesterol metabolism in the incubated egg. KENZO KUSUI. Med. Acad. Nagasaki. *Z. physiol. Chem.* 181, 101-6(1929).—Detns. of cholesterol and cholesterol ester were made on fresh fertile hen eggs and after 3, 7, 14, 18 and 20 days incubation, the digitonin method being used. Free cholesterol showed a steady decrease from 0.2734 g. to 0.1194 g., and cholesterol esters a corresponding increase from 0.0310 g. to 0.1508 g. Up to the 14th day there was a decrease in total cholesterol from 0.3044 g. to 0.2266 g., then an increase to 0.2702 g. on the 20th day. From this it seems highly probable that the embryo is to some extent capable of synthesizing cholesterol. Similar detns. were made with the eggs of a sea turtle, *Thalassochelys corticata*, which require 7 weeks for hatching. The results were similar to those obtained with hen eggs. The free cholesterol decreased while the cholesterol esters increased, and the total cholesterol decreased up to the 30th day but regained half its loss by the 45th day. A. W. D.

Endocrine regulation of blood sugar. L. CERVERA AND F. FORNELIS Y PUIG. *Ciencia* (Barcelona) Oct., 1926; *Rev. sud-am. ericana endocrinol. inmunol. quimioterap.* 11, 210-1(1928); *Physiol. Abstracts* 13, 310.—When HCl comes in contact with the duodenal mucosa, an increase in blood cholesterol takes place if the spleen is intact. If the animal is splenectomized, there is no increased cholesterolemia. H. I. D.

Studies of the inhibitory action of an extract of pancreas upon glycolysis. I. Effect of pancreatic inhibitor on the glycolysis of muscle tissue and muscle extract. ETHEL RONZONI, JEROME GLASER AND DAVID P. BARR. Washington Univ. and the Barnes Hospital, St. Louis. *J. Biol. Chem.* 80, 309-30(1928).—The substance, described first by Winfield and Hopkins (*C. A.* 10, 1213), which inhibits the glycolysis of muscle, was prepd. from the pancreas by a simplified procedure. Glycolysis could be inhibited to the extent of 60%, the inhibition of carbohydrate breakdown being greater than the inhibition in lactic acid formation. The ext. inhibits glycolysis even in the presence of NaF. Evidence is presented to show that the formation of lactic acid by muscle ext. involves the disappearance of both phosphate and carbohydrate with the formation presumably of hexosephosphate. II. Effect of the inhibition upon the glycolysis of malignant tumors. DAVID P. BARR, ETHEL RONZONI AND JEROME GLASER. *Ibid* 331-44.—The inhibitor of glycolysis in muscle exts. has no effect on cancer tissue. The nature of glycolysis in malignant tumors differs from that

in muscle in many respects. Hashing, freezing or extn. prevents glycolysis in tumor tissue; glycogen cannot be used by tumor cells; the phosphate content of these cells is low; and there is no evidence that hexosephosphate is formed in cancer. Since the pancreatic inhibitor acts by preventing esterification, its failure to affect the glycolysis of cancer tissue is, therefore, expected.

ARTHUR GROLLMAN

**Lipide excretion.** V. A study of the partition of the fecal lipides with special reference to bacteria. WARREN M. SPERRY. Univ. of Rochester. *J. Biol. Chem.* 81, 299-319(1929).—The feces excreted by dogs on lipide-free diets were sepd. into portions contg. chiefly (1) bacteria, (2) non-bacterial solids and (3) sol. material. The lipide contents of these fractions were detd. About 40% of the total excretion was contained in the bacterial fraction, most of the rest being in the non-bacterial solids. Essentially the same partition of unsaponifiable material and fatty acids was found for these 2 fractions. The results indicated that fecal lipide excretion is composed of lipides contained in cellular structures (bacteria, epithelial cells, etc.). A. G.

**Glycogen formation in the liver from *d*- and *l*-lactic acid.** CARL F. CORI AND GERTY T. CORI. State Inst. for the Study of Malignant Disease, Buffalo, N. Y. *J. Biol. Chem.* 81, 389-403(1929).—Na *d*-lactate, administered subcutaneously or *per os*, lead to glycogen deposition in the liver. Na *l*-lactate, although absorbed, does not form liver glycogen but is excreted to a large extent in the urine. ARTHUR GROLLMAN

**Studies on cholesterol.** IV. The relation of ovaries and testes to cholesterol metabolism. R. S. RANDLES AND ARTHUR KNUDSON. Albany Med. Coll. *J. Biol. Chem.* 82, 57-9(1929); cf. *C. A.* 22, 978.—The removal of the testes or ovaries from rats had no appreciable effect on the cholesterol content of the blood. A. G.

**Chemical studies of muscle contracture.** II. The distribution of phosphorus in frog muscle during delayed relaxation. H. H. DIXON, H. A. DAVENPORT AND S. W. RANSON. Northwestern Univ. *J. Biol. Chem.* 82, 61-70(1929).—Intraperitoneal injection of hypertonic  $\text{NaH}_2\text{PO}_4$ ,  $\text{NaHCO}_3$ , glycerol, glucose or urea increased the relaxation time of the extirpated gastrocnemii of frogs. The distribution of inorg. P and phosphocreatine in the muscles during fatigue contracture was the same in treated and untreated animals. Dehydration seemed to be the exciting cause of the artificially produced contractures. ARTHUR GROLLMAN

**Secretin.** II. Report. TSUNEYA NISHIKAWA. Tokyo Jikeikwai Med. Coll. *Sei-I-Kwai Med. J.* 47, No. 10, Eng. Abs. 2-3(1928).—HCl exts. of the duodenum of cattle contain activated secretin but  $\text{H}_2\text{O}$  or saline exts. do not. The action of choline and that of histamine on pancreatic secretin are inhibited by atropine. A. G.

**Studies on the glycogen in the central nervous system of some mammals.** II. Changes in the glycogen content of the central nervous system during the postnatal development of some mammals. HYOSAKU TANAKA. Jikeikai Med. Coll. *Sei-I-Kwai Med. J.* 47, No. 10, Eng. Abs. 4(1928); cf. *C. A.* 22, 3690.—On the first day after birth the glycogen content of the nervous system of guinea pigs is high. It then decreases until the first or second week of life after which it again increases. At one month glycogen is found both intra- and extra-cellularly. Between the 3rd and 6th months, it is const. in amt. but somewhat decreased over the preceding period. A. G.

**The interchange of substances between mother and fetus.** E. BRANDSTRUP. Copenhagen Univ. *Klin. Wochschr.* 7, 2340(1928).—NaCl, urea, glucose and amino acids diffuse slowly into the blood of the fetus when they are injected into the mother (rabbit). Sucrose appears not to diffuse from the mother into the fetus.

MILTON HANKE

**Excretion of iodine by the gastric glands.** LUDWIG HEILMEYER STURM. Univ. Jena. *Klin. Wochschr.* 7, 2381-3(1928).—The intravenous injection of NaI leads to the almost immediate excretion of I into the stomach. About 14% of the injected I is so excreted. The concn. of I in the gastric juice is, under these conditions, about 3 times as great as that of the saliva. The injection of iodides increase the secretion of HCl into the stomach. Inhalation of EtI leads to the appearance of I in the gastric juice.

MILTON HANKE

**Carbohydrate metabolism and the catabolism of the glucose molecule.** II. Lactic acid in the blood. ERICH SCHNEIDER AND ERNST WIDMANN. *Klin. Wochschr.* 8, 646-8(1929); cf. *C. A.* 23, 3019.—The liver is the only organ that removes lactic acid from the circulation. Lactic acid that is injected into the portal vein does not appear in the general circulation. Dihydroxyacetone is not converted into lactic acid; and *vice versa*. The lactic acid content of venous and of arterial blood is identical in a resting tissue.

MILTON HANKE

**The mode of action of the thyroid hormone.** RUDOLF WEIL. *Klin. Wochschr.* 8, 652(1929).—Thyroxine, in very minute doses (1:400,000), increases the rate of autoly-

sis of liver cells (*in vitro*) 50% in 24 hrs. W. attempts to explain all of the previously observed phenomena associated with diseases of the thyroid gland on the basis of increased or decreased autolysis.

MILTON HANKE

Oscillations of blood-sugar values within brief periods, and the blood-sugar curve on uniform ingestion of glucose. OTTO J. NIELSEN. Univ. Copenhagen. *Biochem. J.* 22, 1490-8(1928).—Detns. of blood sugar in fasting individuals at complete rest, made at intervals of 1-5 mins. for a period of  $\frac{1}{2}$ -2 hrs., failed to yield previously described oscillations of the blood-sugar curve. In normal individuals N. found an almost horizontal curve; in insulin- and diet-treated diabetics, a rising curve; in diabetics merely treated with diet, a falling curve; in diet-treated diabetics with advanced kidney insufficiency, an almost horizontal curve.

BENJAMIN HARROW

The lactic acid and glycogen contents of kidney cortex. JAMES T. IRVING. Oxford Univ. *Biochem. J.* 22, 1508-13(1928).—The production of lactic acid in excised kidney cortex is, like that in muscle, a reaction of some rapidity. Since under these conditions the glycogen content changes but little, it is deduced that the major part of the lactic acid must be formed from some other source. Glucose may be one of the precursors.

BENJAMIN HARROW

The estrus-producing hormone: its preparation and standardization in a water-soluble form. HAMISH ALLAN, FRANK DICKENS, EDWARD C. DODDS AND FREDERICK O. HOWITT. Middlesex Hospital, London. *Biochem. J.* 22, 1526-43(1928).—The hormone is standardized by injection into rats. One unit of activity is that quantity of material required to produce a full estrus response in 50% of the rats used. Estrus is considered to be present when cornified cells only are shown in the vaginal smear. For the prepn. of the ext. dissected and minced placenta are extd. with boiling  $\text{Ba}(\text{OH})_2$  soln., filtered, concd. by evapn., extd. with  $\text{BuOH}$ , the solvent is distd. off under diminished pressure, the residue dissolved in hot water and filtered, the ppt. washed with ether and the washings are added to the ether exts. of the aq. portion. The combined ether ext. is washed with water, concd. to an oily residue and freed from the remaining  $\text{BuOH}$  by distn. *in vacuo* with a little water. The residue is dissolved in alc., added to water, the suspension shaken with ether, the ext. washed with 0.1 N HCl and then with water until the washings are free from chloride. The ethereal soln. is evapd., the residue dissolved in alc., and then poured into water. The alc. is removed by evapn., 5%  $\text{Ba}(\text{OH})_2$  is added, and the mixt. heated under reflux for 1-2 hrs. The material is filtered, and the ppt. extd. with successive quantities of hot alc. The alc. ext. is evapd. to small vol. and the treatment with  $\text{Ba}(\text{OH})_2$  is repeated. The combined filtrates from the first and second boilings with  $\text{Ba}(\text{OH})_2$  are heated on a water bath and the Ba is removed as  $\text{BaSO}_4$ . The final product is acid in reaction ( $\text{pH}$  5) and can be dialyzed through parchment.

BENJAMIN HARROW

Variations in some of the constituents of the blood throughout the menstrual cycle in normal women. HAROLD G. CLOSE AND ARTHUR A. OSMAN. Guy's Hospital, London. *Biochem. J.* 22, 1544-7(1928).—There is a slight decrease in the serum bicarbonate, and a slight increase in the serum chloride.

BENJAMIN HARROW

The automatism and excitability of the surviving mammalian intestine during oxygen deficiency. ARNOLD SEILER. Univ. Bern. *Z. Biol.* 88, 63-75(1928).—The intestine is automatically active for hrs. Elec. stimulation of the tissue shows similar results both during  $\text{O}_2$  deficiency and  $\text{O}_2$  supply. The reactions are like that of choline. There is a marked difference between this intestine and the heart of cold-blooded animals. The excitability of the latter is greatly diminished in  $\text{O}_2$  deficiency.

F. K.

The influence of liver dialyzates on the surviving heart of cold-blooded animals and on the surviving mammalian intestine. WALTER HOFMANN. Univ. Bern. *Z. Biol.* 88, 119-24(1928).—The liver dialyzates activate the frog heart. The beat counts may remain unchanged or retarded. The effect on the intestine is two phased—a stimulation and an inhibition of activity.

FRANCES KRASNOW

Inhibiting action of sucrose on taurocholate, saponin, and oleate hemolysis. A. C. ROY AND K. C. SEN. *J. Indian Chem. Soc.* 6, 89-92(1929).—Sugar has a great inhibiting action upon the rate of hemolysis of sheep blood by saponin, oleate and taurocholate. Hemolytic behavior of mixtures of hemolytes. KSHITISH CHANDRA SEN AND NARENDRA NATH MITRA. *Ibid* 111-20.—The hemolytic effect of saponin, taurocholate and oleate upon sheep corpuscles is compared with the effect of mixts. of these same substances. The effect of mixts. is approx. the sum of the effects of the components. HCl accelerates the hemolytic action of saponin, while NaOH retards it.

W. D. LANGLEY

Alkali reserve and oxygen capacity of arterial and of venous blood. L. M. HURK-

THAL, A. V. BOCK, J. H. TALBOT AND D. B. DILL. Mass. General Hosp. *J. Biol. Chem.* 81, 681-5(1929).—In a series of normal subjects at rest and at work and in another series of pathol. subjects only small differences were found between arterial and venous blood both in respect to  $\text{CO}_2$  capacity at a partial pressure of 40 mm. of  $\text{CO}_2$  and in respect to  $\text{O}_2$  capacity. In 19 observations on  $\text{O}_2$  capacity there were only 3 in which the  $\text{O}_2$  capacity of arterial blood was greater than that of venous blood and none in which the difference was as great as 1 vol. % in either direction. It is evident that for most purposes the difference between arterial and venous blood is unimportant.

A. P. LOTHROP

The conditions of activity in endocrine glands. XXIV. Asphyxial stimulation of the denervated adrenal gland. R. L. ZWEMER AND H. F. NEWTON. Harvard Med. School. *Am. J. Physiol.* 85, 507-11(1928).—In dogs whose hearts had been denervated by operation, whose sympathetic nerves to the thyroids and liver were severed and whose adrenals had been inactivated by removal of one and denervation of the other, asphyxia of the denervated adrenal induced by compression of the aorta for 10 secs. was followed after release by a great increase in pulse rate. Conclusion: The denervated adrenal medulla responds to asphyxial stimulation by an increased production of adrenaline.

J. F. LYMAN

The effect of daily transplantation of the anterior lobe on the course of pregnancy in the rat and mouse. EARL T. ENGLE AND CAMILLE MERMOD. Stanford Univ. *Am. J. Physiol.* 85, 518-26(1928).—Daily transplantation of fresh anterior lobe of the pituitary into rats or mice from 1 to 4 days after copulation prevented pregnancy; transplants introduced from 11 to 13 days after the beginning of pregnancy caused resorption or expulsion of the fetus. Treatment from the 15th to 17th day of pregnancy did not always interrupt gestation. The gonad-stimulating hormone of the anterior pituitary stimulates the production of a large no. of ovarian follicles, which in turn causes a proliferation of the uterine mucosa that is incompatible with pregnancy.

J. F. LYMAN

The effect of the administration of excessive amounts of water. III. The volume and composition of the bile. ALBERT M. SNELL AND LEONARD G. ROWNTREE. Mayo Clinic and Mayo Foundation, Rochester, Minn. *Am. J. Physiol.* 85, 577-80(1928).—The administration of  $\text{H}_2\text{O}$  in large amts. (50 cc. per kg. body wt.) every half hour produced a temporary decrease in the amt. of bile secreted by animals with permanent biliary fistulas, a decreased total output of bile acids and under certain conditions a decrease in the concn. of bile acids.

J. F. LYMAN

The physiology of the gastric secretion. XIII. The response of the glands to substances applied to the gastric mucosa. J. I. FARRELL. Northwestern Univ. *Am. J. Physiol.* 85, 672-84(1928); cf. *C. A.* 22, 3205.—Expts. on dogs with a pouch of the entire stomach and a duodeno-esophageal anastomosis showed that the gastric glands can be stimulated by the local chem. action of moderate amts. of alc. and by 1% solns. of lactic acid. Water did not stimulate by local chem. action unless warmed to 52.5°.  $\text{NaHCO}_3$  soln. (1%) produced a slight inhibition of the continuous secretion. Bitters had no stimulating effect unless dissolved in alc. Raw meat juice applied to the gastric mucosa stimulated gastric secretion; boiled meat juice did not. Raw egg white, milk, casein and sucrose had no stimulating effect. Coffee was slightly stimulating; fats and fatty acids inhibited gastric secretion. The gastric digestion of meat, casein and egg white liberates secretagogues which excite gastric secretion by local contact with the gastric mucosa. Strong irritants (mustard oil) produced a large amt. of mucoid fluid contg. no acid.

J. F. LYMAN

The distribution of the estrus-producing and estrus-inhibiting hormones in the ovary of the cow. W. B. PAYNE, H. VAN PEENAN AND G. F. CARTLAND. Upjohn Co., Kalamazoo, Mich. *Am. J. Physiol.* 86, 243-7(1928).—The cholesterol-free unsaponifiable fractions of the fat of corpus luteum and ovarian residue (*C. A.* 21, 952) were tested for estrus-producing (causing estrus in sprayed females) and estrus-inhibiting hormones (delay in estrus in sexually mature females). In terms of the dried gland the corpus luteum contained 35 rat units and the ovarian residue 66 rat units of estrus-producing hormone per kg. The estrus-inhibiting hormone of the ovary seems to be localized in the corpus luteum.

J. F. LYMAN

The effect of increased blood flow on the ratio between oxygen consumption and pulmonary ventilation. EDWARD D. CHURCHILL. Mass. Gen. Hosp. *Am. J. Physiol.* 86, 274-84(1928).—The ventilation and  $\text{O}_2$  absorption of each lung of an anesthetized cat were measured separately and simultaneously. By occluding one branch of the pulmonary artery, or one set of pulmonary veins, the total output of the right ventricle was diverted to the contralateral lung. Such procedure caused a marked increase in  $\text{O}_2$

absorption of that lung, probably because of the increased blood flow in the lung, resulting in an increase of the functional diffusing surface. J. F. LYMAN

The resistance of animals to barometric pressure in atmospheres of various oxygen concentrations. RODOLFO MARGARIA. *Arch. sci. biol.* (Italy) 13, 1-18(1929).—These expts. were performed in a pneumatic bell-jar on guinea pigs with the technic previously described (*C. A.* 23, 875). The ventilation of the bell-jar at atms. corresponding to that above 6000 m. altitude was maintained with a mixt. of  $O_2$  and air of known compn. The resistance of the animals to the diminution of the partial pressure of  $O_2$  in the alveoli is less, the greater is the % of  $O_2$  in the atm. inspired. The presence of  $CO_2$  in the inspired air increases the resistance of the guinea pigs to anoxemia; the decreased resistance in an atm. contg. high concns. of  $O_2$  is supposed to be due to a relative diminution of  $CO_2$  pressure in the pulmonary alveoli. PETER MASUCCI

The electrical resistance of nerve tissue as a function of temperature and under the influence of ether and chloroform. NICOLA GAVRILESCU. *Arch. sci. biol.* (Italy) 13, 39-52(1929).—Dogs were decapitated and the spinal cord was removed immediately. This tissue was used to study (1) the effect of temp. and (2) of time on cond. The action of ether and  $CHCl_3$  on cond. was studied on (a) the frog sciatic-gastronomic neuromuscular prepn., (b) the dog phrenic-diaphragmic prepn., (c) the brain *in vivo*, and (d) the juice of the white substance of the brain. Results: (1) The elec. resistance of nerve tissue diminishes with the increase in temp. The decrease is not as regular as that noted in solns. of electrolytes. (2) The resistance of nerve tissue at const. temp. increases with time up to a certain point; then it diminishes rapidly and continuously (probably owing to putrefactive process). (3) The elec. resistance of nerve tissue in a living animal or of living nerve tissue out of an animal increases under the action of anesthetics. This action is in part reversible. (4) In dead nerve tissue and in the juice of the white substance of the brain (myelin) anesthetics also produce an increase of elec. resistance. PETER MASUCCI

Resistance to barometric depression in mixtures of air and carbon dioxide. RODOLFO MARGARIA. *Arch. sci. biol.* (Italy) 13, 19-30(1929).—The method used was similar to that of *C. A.* 23, 875. Guinea pigs were used. The presence of  $CO_2$  in the inspired air even up to a concn. of 20% fails to influence the resistance of the guinea pigs to depression. PETER MASUCCI

Studies on carbohydrate metabolism on a high mountain. G. FERRALORO. *Arch. sci. biol.* 13, 109-26(1929).—The aim was to study the blood-sugar curve at a high altitude (Col d'Olen 2900 meters high) in subjects to whom was administered *per os* a large dose of glucose, and to compare these data with values obtained with the same subjects at lower altitudes (Turin). At high altitudes the blood sugar was constantly higher; in seven subjects it ranged from 0.165 to 0.132% compared to 0.101 to 0.120% at Turin. The high glucemic titer is attributed to several factors: rarification of air, solar rays and hyperadrenalinemia. The limit of tolerance to glucose at high altitudes was confirmed. The glucemic curve was followed in 3 subjects after the ingestion of glucose in amts. close to the limit of individual tolerance. The hyperglucemia obtained at high altitudes was almost the same as that obtained at low altitudes. This indicates that the combustion of sugar at high altitudes is not more active but more regular. The increased limit of tolerance to glucose is ascribed to a diminished renal permeability which is probably caused by the high glucemic titer normally prevailing at high altitudes. PETER MASUCCI

The secretion of the glands in the crop of the pigeon. F. DULZETTO. *Rell. soc. ital. biol. sper.* 3, 949-51(1928); cf. *C. A.* 22, 1997.—The glands in the crop of the pigeon secrete a mucous-like substance and a serous fluid. These approach physiologically the secretion of the salivary glands, except that they are the functional product of the same cellular element, instead of distinct elements as in salivary secretion. PETER MASUCCI

The fall in osmotic pressure and hydrogen-ion concentration of arterial, portal and hepatic vein blood, and a method for its measurement. C. HÄBLER AND K. WEBER. Univ. Würzburg. *Biochem. Z.* 195, 364-75(1928).—The osmotic pressure of the portal blood is not higher than that of the arterial while that of the hepatic vein is only slightly higher. If, however, the  $CO_2$  tension is taken into consideration the osmotic pressure of the portal blood was definitely higher than the arterial but no difference was found between the portal and hepatic vein blood. The portal blood is generally more acid than the arterial while the hepatic blood is more alk. than the portal. S. M.

Tissue respiration. V. The participation of protein in the tissue respiration. K. SINGER AND O. PÖPFELMANN. Med. Poliklinik, Rostock. *Biochem. Z.* 205, 63-70(1929).—The amt. of metabolized protein as detd. directly by the g. N per hr. varies

within very narrow limits, and practically no difference was found in studies made on liver tissue from mice, man or bull. The wide divergence in size or in intensity of metabolism being considered it is concluded that the  $\text{NH}_2$  formation of surviving tissue is largely independent of these factors. The protein metabolism of the living and of the surviving tissue, up to the dog, is the same but in larger mammals the tissue protein metabolism is 17 times as great as in the living organism. S. MORGULIS

Variations in the blood sugar concentration in man in the course of the day. L. M. KRASNYSKII. North Caucasian State Univ., Rostov-Don. *Biochem. Z.* 205, 180-5(1929).—The blood sugar level in the course of the day gives a wave-like curve, the no. and height of whose crests depend upon the food taken. In fasting there is also a succession of ups and downs in the blood sugar curve; only these variations are few and the max. never exceeds 20 mg. Food causes a great and quick rise in the sugar content. This is not dependent upon nerve impulses from the digestive tract, but directly upon the carbohydrate content of the food. S. MORGULIS

Studies on the physiology of the surviving mammalian heart. VI. The sugar consumption of the heart of thyroidectomized as well as of normal and thyroidectomized cats treated with thyroxine. GEORG AMBRUS. Königl. ungar. Univ., Budapest. *Biochem. Z.* 205, 194-213(1929); cf. C. A. 23, 2748.—The sugar consumption of hearts from thyroidectomized cats is much smaller than that of normal animals. The difference in sugar consumption is greater the sooner after thyroidectomy the heart is tested, so that apparently in the course of time some substitute for the thyroid hormone is produced, or else the injured cardiac muscle recuperates. The heart from normal cats treated with thyroxine has a larger sugar consumption than that from untreated cats, while the hearts from thyroidectomized cats treated with thyroxine may consume as much sugar as those from normal animals. S. MORGULIS

The significance of bile acids in fat resorption. II. F. VERZAR AND A. KÜTHY. Univ. Debreczen. *Biochem. Z.* 205, 369-79(1929).—Fatty acids in finely emulsified form yield clear diffusible, apparently molecularly dispersed solns. with the paired salts of Na taurocholate and glycocholate, which are stable even at  $p_H$  6.2. This explains the possibility of intestinal absorption in neutral or even acid medium. The alk soaps which could be in soln. only at  $p_H$  9.0 cannot exist at the reaction of the intestine. The bile acids make it possible for the fatty acids to be in soln. even at an acid reaction. S. MORGULIS

Hemopoietic action of bilirubin and of other hemoglobin derivatives. F. VERZAR AND A. ZIH. Univ. Debreczen. *Biochem. Z.* 205, 388-401(1929).—Bilirubin fed to rabbits in 0.5-25 mg. amts. has a strong hemopoietic effect. Hemibilirubin has a similar effect but biliverdin acts very poorly. Hemoglobin and hematin also have a hemopoietic effect by giving rise to bilirubin in the organism. In large doses bilirubin may occasionally produce an opposite effect (hemolytic), as do other hemopoietic organ extracts prep'd. from spleen or marrow. Lower degradation products like the porphyrins or bilirubinic acid seem to be without action. The bilirubin effect does not depend upon the spleen and can be produced even after splenectomy. Bile, too, has a hemopoietic effect in small doses and in large doses acts hemolytically. It is suggested that the bilirubin or allied substances formed during the normal destruction of red cells serves as the physiol. stimulus to further red cell production. S. MORGULIS

Hemopoietic action of different organs. A. ZIH. Univ. Debreczen. *Biochem. Z.* 205, 402-8(1929).—Feeding normal rabbits on bone marrow as well as spleen may produce either a hemopoietic or a hemolytic effect. Feeding lymph nodes has a similar action. Muscle and lung are practically without any effect, and even feeding liver does not always have a hemopoietic influence, a reduction in the number of red cells being occasionally the result. All organs acting hemopoietically belong to the reticulo-endothelial system and their expts. may contain hemoglobin decompn. products. S. M.

Oxidation of glutamic acid in the animal organism. A. VON BEZNÁK. Univ. Debreczen. *Biochem. Z.* 205, 420-32(1929).—Subcutaneous administration of  $\beta$ -phenylglutamic acid to dogs and rabbits increases the excretion of hippuric acid, the increase in some instances amounting to 13% of the  $\beta$ -phenylglutamic acid. It is concluded that the glutamic acid in the animal organism does not undergo only  $\alpha$ -oxidation but that oxidation in the  $\beta$ -position also takes place. S. MORGULIS

The influence of electrolytes on the sugar metabolism. I. ABELIN. Physiol. Inst. Univ. Bern. *Biochem. Z.* 205, 457-66(1929).—The administration of phosphate,  $\text{NaHCO}_3$  and some other electrolytes causes an alteration in the metabolism of ingested carbohydrates, which manifests itself in a diminished glycogen deposition in the liver and a lowering of the respiratory quotient.  $\text{NaHCO}_3$  has a strong ketogenic effect upon

the rats, probably because of change in liver glycogen since it depresses glycogen formation and carbohydrate utilization.

S. MORGULIS

The reducing substance content of rabbit organs at different blood-sugar levels. G. PREYER. Med. Klinik, Basel. *Biochem. Z.* 206, 1-15(1929).—The reducing substances of organs are detd. following complete hydrolysis. Under normal glucemia the relatively high content of the reducing substance of lung and brain is particularly notable. Under conditions of hyperglucemia or hypoglucemia the adrenals show a particularly high content of reducing substance. In states of excitation (hyperglucemic or synthalin convulsions) the diminution in the reducing substances is most marked in the brain. The muscles are the primary sites so far as the influence of insulin or synthalin on carbohydrate metabolism is concerned. Lethal doses of insulin or synthalin cause practically the complete disappearance of carbohydrate from the muscles. In insulin hypoglucemia the muscles are nearly carbohydrate-free, whereas the liver still contains considerable quantities. Symmetrically located muscles have the same contents of reducing substance, but different muscle groups may vary greatly from each other. The individual muscle components, however, of the group have practically the same percent of reducing substance. The body muscles are quite different from the extremity muscles in this respect.

S. MORGULIS

The ammonia content and the ammonia formation in blood. X. Origin of blood ammonia. W. MOZOLOWSKI. Univ. Lemberg. *Biochem. Z.* 206, 150-7(1929).—The blood  $\text{NH}_3$  comes partly from the adenylic acid but the deamination of this acid cannot account for the entire amt. of  $\text{NH}_3$  produced. The purine base content of the blood of various animals corresponds to their ability to produce  $\text{NH}_3$ . The blood of man, pig, or rabbit with great capacity for producing  $\text{NH}_3$  contains more purine bases than the blood of cows or horses which forms little  $\text{NH}_3$ . In fresh blood the purine bases are almost entirely in the form of nucleotides, principally as adenylic acid. Free adenine is not found in blood. The adenylic acid of the blood changes to inosinic acid by losing the  $\text{NH}_3$ , and the inosinic acid undergoes further hydrolysis with liberation of  $\text{H}_2\text{PO}_4$ .

S. MORGULIS

The physiology of glands. CXIV. Studies on activation of adrenaline by thyroxine. LEON ASHER AND FRITZ ZIMMERMANN. Univ. Bern. *Biochem. Z.* 206, 369-400(1929).—A method is described whereby the glycogen content of 2 muscles of the hind limbs of rats can be detd. without disturbing the physiol. condition of these muscles. By this method the glycogen content was found to be higher than generally given, namely 0.79% on the av. In control expts the av. absolute difference was 2.94%. Adrenaline (1:10,000) caused a diminution of 21.8%; adrenaline (1:1000) 25.28%; and adrenaline (1:10,000) +2% novocaine 28.85%, reduction of the glycogen. The liver glycogen was reduced to 1.79% with adrenaline 1:10,000 or to 0.90% with adrenaline 1:1000. If a thyroxine injection precedes that of the adrenaline by 6 hrs. the loss of glycogen in the muscle increases to 37.06% while that of the liver drops to 0.257%. Thyroxine thus enhances greatly the action of adrenaline on the carbohydrate metabolism. Thyroxine apparently activates adrenaline and the autonomic nervous system generally.

S. MORGULIS

Lactic acid metabolism of the central nervous system. II. HANS JUNGSMANN. Univ. Breslau. *Biochem. Z.* 206, 457-67(1929); cf. *C. A.* 23, 882.—Addn. of glucose to the fluid in which the surviving cord is sustained leads to an increased lactic acid formation both in  $\text{O}_2$  and in  $\text{N}_2$ , but whereas in the presence of  $\text{O}_2$  the increase is found only in the outside fluid, in  $\text{N}_2$  it is found also in the cord itself. Under direct faradic stimulation there is not a diminution of lactic acid, as when no glucose has been added to the fluid, but a slight increase. Insulin causes a reduction in the lactic acid production by the surviving cord both in  $\text{O}_2$  and in  $\text{N}_2$ . When stimulated under similar conditions there is no diminution of the lactic acid in an  $\text{O}_2$  atm. but only in the  $\text{N}_2$ . The combined addn. of glucose and insulin likewise causes a diminution in lactic acid. The presence of a glucolytic enzyme could be demonstrated in the outside fluid.

S. MORGULIS

Blood sugar regulation. III. Influence of increased outside temperature on the blood sugar of the rabbits and dogs. PAUL WEYL. Univ. Köln. *Biochem. Z.* 206, 485-502(1929).—In rabbits exposed to a temp of  $32-37^\circ$  for 5-7 hrs. a hyperglucemia occurs, usually within 5 mins., but the blood sugar diminishes after 2-3 hrs and generally is back to the normal level by the end of the expt. Even by prolonging the expt. for 40 hrs. at  $30-32^\circ$  there was neither hyperglucemia nor hypoglucemia. However, if the animals betrayed strong exhaustion the hyperglucemic condition would persist. If after prolonged exposure to high temp. the animal was transferred to the cold there was a slight hyperglucemia, but if the transfer to the cold was made after a brief sojourn in the warm the hyperglucemia continued to increase. In dogs either long or

short exposures to high temp. (30–38°) caused neither hyperglucemia nor hypoglucemia. The statement that the blood sugar level is lower at high temp. than at low temp. cannot be sustained. S. MORGULIS

The influence of the blockade of the reticulo-endothelial system on the blood sugar level. E. I. STERKIN AND E. L. KERNER-POSHENYAN. State Med. Inst. Charkov. *Zhur. exptl. Biol. Med.* 10, 431–8(1929).—A single intravenous injection of India ink, Vitargol, collargol, trypan blue and Congo red does not produce any noticeable effect on the blood sugar level. S. MORGULIS

The application of Loeb's formula to the "pessimum" phenomenon. A. MAG-NITZKII. Univ. Leningrad. *Zhur. exptl. Biol. Med.* 10, 484–99(1929).—The phenomenon described by Vvedenskii as "pessimum" is a form of parabiosis observable in the terminal app. of a motor nerve. This depends both upon the absolute concn. of ions and their interrelations in the terminal portion of the nerve. An increase in  $K$  in Loeb's ratio of concn.  $Na/concn. Ca = K$  interferes, and a diminution in  $K$  promotes its appearance. Furthermore, the presence of  $Ca$  ions is indispensable while that of  $K$  is not. It is pointed out that the  $Na$  and  $Ca$  antagonism is physiol. and not physicochem. S. MORGULIS

Physicochemical analysis of sympathetic influence on skeletal muscle. I. Potentiometric titration of the perfusion fluid as a method of studying the physicochemical properties of muscle. E. M. KREPS AND V. V. STRELZOV. Military Med. Acad., Leningrad. *Zhur. exptl. Biol. Med.* 10, 558–70(1929).—II. Influence of sympathetic innervation on the curve of potentiometric titration of the muscle perfusion fluid. *Ibid* 570–85.—The study of the buffering effect of active muscle has been carried out under 4 different conditions: on working normal muscle, on working normal muscle under the influence of sympathetic stimulation, on working muscles deprived of sympathetic stimulation and on working muscles poisoned by ergotamine following cauterization of the adrenals. Both methods of eliminating the sympathetic innervation (section or poisoning) lead to a weakening of the clonic working capacity and to an increased contracture. In the exclusion of the sympathetic innervation the connection between the functional properties of the muscle and the constancy of their physicochem. medium is brought out very strongly. This constancy of the physicochem. condition of the muscle is conducive to satisfactory activity with little contracture. The presence of sympathetic innervation hides this relationship between physicochem. conditions and the functional property, and the perfusion fluid of such muscles may be either of a const. or of a very variable compn. The expts. with the sympathetic nerve excluded gave more definite results than those in which the sympathetic was stimulated. III. The effect of sympathetic innervation on the passage of lactic acid from the working muscle into the blood stream. *Ibid* 586–606.—Three potentiometric titration curves (resting condition, immediately after work, and 30 mins. after work) were obtained with each muscle under the 4 different exptl. conditions enumerated before, which permitted the calcn. of the concn. of buffering substances and especially of the lactic acid in the perfusion fluid. The concn. of lactic acid is lowest in the "rest" curve and and highest in the "work" curve. Removal of the sympathetic innervation by any method markedly increases the passage of lactic acid into the blood stream, though the increase is only two-fold where the nerve is sectioned and twenty-fold where the nerve is excluded through ergotamine poisoning. The muscle deprived of its sympathetic innervation thus rapidly loses its carbohydrate store. Most economical disposition of lactic acid is observed in expts. where the working muscle is also undergoing sympathetic stimulation, the rise of acetic acid in the perfusion fluid being at a min. In the absence of the sympathetic innervation there is increased passage of  $H_2PO_4$  into the blood and the reaction shifts towards alkalinity owing to the relative increase in the dibasic phosphate. This increases the buffering property aiding in the accumulation of lactic acid. The return to the "resting" condition after work is more rapid in expts. where the sympathetic was stimulated. S. MORGULIS

Experimental investigations on mineral equilibrium. P. L. VIOLETTE AND P. DUFOURT. *Presse médicale* No. 52, 1011–3(1928); *Bull. soc. hyg. aliment.* 16, 496–7(1928).—The distribution of water in the organism seems to be detd. by a certain no. of equil., of which the following are particularly important: osmotic, acid-base, lipocytic, mineral and protein. In order to det. the conditions of the mineral equil., V. and D. detd the hydrating power of various salt solns. on the gastrocnemius muscle of the frog. By studying the imbibition curves of the muscles and the ionic compn. of the simple or complex solns. used, they found that there are definite relationships between these ions (alkali and alk. earths) and the imbibition phenomena. It would seem that the cation plays a much more important part than the anion:  $Na$ , whether as sulfate

or chloride, has much less pronounced hydrating properties than K and especially than Mg, which has the most pronounced hydrating properties of all the metals. Inversely, Sr salts have dehydrating properties, which are much less pronounced than those of Ca. The most important data are, therefore, the alk.-earth/alkali ratio, or more simply Ca/Na, which approximates very closely to the former. In normal serum the value of this ratio is 0.03. Normal serum has dehydrating properties towards the gastrocnemius muscle of the frog, while Ringer-Locke soln., in which the ratio is 0.011, has hydrating properties towards the same muscle. Under the same exptl. conditions equil. was attained for Ca/Na = 0.023. A. PAPINEAU-COUTURE

Experiments on the action of lipoids. II. Histological and physiological changes of the thyroid, suprarenals and liver in rabbits receiving lecithin injections. ALDO BARCHIESI. *Rass. clin. terap. sci. affini* 27, 366-9(1928); cf. C. A. 23, 2204.—Four groups of rabbits were used. I served as the controls; the 3 others were treated with various amts. of a mixt. of lecithin, lutein and cholesterol esters for 54 days, each group receiving 31 injections. The single doses given to II, III and IV consisted of 0.040 g., 0.200 g. and 0.400 g., resp., of lecithin and of 0.016 g., 0.080 g., and 0.160 g., resp., of lutein and cholesterol esters in 1, 2.5 and 5 g., resp., of physiol. serum. Groups II and III gained wt. more rapidly than did I, while IV first increased in wt. for about 45 days and then lost wt. very rapidly. The histological examn. revealed that the thyroid glands of II and III exhibited a greater no. of large vesicles than did I. Large vesicles were also more frequent in IV than in I. In the cellular elements contained in the vesicles of IV, an active formation of colloid seemed to occur. From these observations B. concluded that the lipid mixt. injected caused a slight increase of the thyroid activity in the animals receiving small doses and a great increase in the animals receiving large doses. With II the cortical and chromaffin cells of the suprarenals were greatly increased in vol.; with III the increase was smaller. With IV the cortical cells gained in vol., while the vol. of the chromaffin cells was slightly below normal. The size of the hepatic cells was markedly reduced in II, III and IV. The glycogen content of the liver was smaller in II, III and IV than in I. G. SCHWOCH

The action of lecithin on the fat metabolism. A. CRUTO. *Rass. clin. terap. sci. affini* 27, 363-5(1928).—The liver and the muscles of the guinea pigs used by Barchiesi (C. A. 23, 2204) with bioplastina were analyzed for their content of lecithin, cholesterol and fatty acids. The 4 groups of guinea pigs included fasting animals (I), fasting animals receiving bioplastina (II), animals of a normal diet (III), and animals on a normal diet and receiving bioplastina (IV). The av. values for the fatty acids of the liver were in I: 6.06%, in II: 2.58%, in III: 0.59%, in IV: 0.58%. For the muscles C. obtained in I: 0.40%, in II: 0.46%, in III: 5.97%, in IV: 5.80%. As to the values obtained for cholesterol and lecithin, no essential differences were noted when comparing group I with II and group III with IV. From his expts. C. draws the following conclusions, which agree with the results obtained by B. The fat catabolism is increased by injections of the lecithin prepn.; at the same time also the fat anabolism rises. In case of IV the increase in anabolism equals that in catabolism; thus the equal values found for the fatty acids in the groups III and IV are accounted for. In case of II, however, only the increase in catabolism is expressed; thus the difference between the liver fatty acids in I and II is explained. G. S.

Role of secretin in the regulation of the alkali reserve of the blood. A. O. WOINAR. Odessa Med. Inst. *Arch. ges. Physiol.* (Pflüger's) 221, 144-9(1928).—See C. A. 23, 2472. G. H. SMITH

Effect of removal of the hemispheres upon the weight, the gas metabolism and the temperature of birds. N. A. POPOV AND B. I. BAYANDUROV. Univ. Tomsk. *Arch. ges. Physiol.* (Pflüger's) 221, 410-18(1929).—See C. A. 23, 2471-2. G. H. SMITH

True reaction of the cerebrospinal fluid. A. BECK AND H. J. LAUBER. Univ. Kiel. *Arch. ges. Physiol.* (Pflüger's) 221, 499-502(1929).—Under normal conditions the  $p_H$  of the spinal fluid is the same as that of the blood (7.3-7.36). G. H. SMITH

Specific dynamic action of intravenously injected amino acids. ELIZABETH MULERT. Univ. Hamburg. *Arch. ges. Physiol.* (Pflüger's) 221, 599-604(1929).—Although sp. dynamic action depends to a considerable extent upon the nutritional state of the animal, glycine given intravenously exerts an effect, alanine does not. G. H. SMITH

Specific dynamic action and the hypophysis. Experiments on rats. R. NOTH-HAMM. Univ. Hamburg. *Arch. ges. Physiol.* (Pflüger's) 221, 763-7(1929).—By feeding rats with the anterior lobe substance of the hypophysis of cattle for a period of from 2 to 3 weeks the sp. dynamic action is increased by about 26%. G. H. SMITH

**Biochemical investigations on the specificity and transformations of the plasma proteins.** H. BERRY. *Compt. rend.* 188, 740-2(1929); cf. C. A. 22, 3927.—Proteinic sugars exist in varying proportions in different plasmas. The ratios, protein C/proteinic sugar and protein N/proteinic sugar, grossly evaluate the blood proteins and can be used to follow variations in these substances. Different species show differences in the plasma proteins. There is a regulatory mechanism which serves to maintain an equil. between the plasma proteins and the proteinic sugar, but these substances can, and do, vary within narrow limits and play an important part in the various changes taking place in the organism.

H. G. SMITH

**The effect of parathyroid hormone on the structure of bone.** C. G. LAMBIE, W. O. KERMACK and W. F. HARVEY. *Nature* 123, 348(1929).—Osteitis fibrosa and osteomalacia are associated with tumors and hyperplasias of the parathyroid glands and such a condition may result in the secretion of excessive amts. of the hormone causing hyperglucemia, negative Ca balance and presumably loss of bone Ca. These authors have studied the effect of prolonged administration of parathyroid hormone to rats, 10 units a day, for 21 days. Histological examn. showed a thinning of the trabeculae of all bones and slight changes in the cortex and epiphyseal cartilages of some. The dried bones were more brittle and fibrous than those of normal controls. There was less ash on ignition but the % of Ca in the whole bones was not altered. Therefore the ash of the bones of the treated rats contained more Ca than the untreated, which finding may indicate a change in the form in which Ca exists in the bones.

H. G. SMITH

**The potassium content of the heart.** H. ZEEHUISEN. *Arch. néerland. physiol.* 12, 295-7(1927).—The K content of the heart falls when the perfusion fluid contains less KCl than 0.02%. If the perfusion is continued the removal of K continues even after the heart has stopped. About 15% of the frog hearts perfused with K-free Ringer soln. will beat again after cessation of activity from perfusion. The auricles of fresh tortoise heart contain 0.058% K and the ventricles 0.14%. The auricle takes up 0.072 mg. per g. and the ventricle 0.016 mg. per g. when perfused with 40 mg.  $\text{UO}_2(\text{NO}_3)_2$  per l.

M. H. SOULE

**The relation of body temperature to the blood sugar content.** CARL SCHWARZ and EDUARD KASPER. *Tierarztl. Hochsch., Vienna. Biol. gen.* 3, 689-98(1927); *Ber. ges. Physiol. expül. Pharmacol.* 45, 651.—When their habitat is changed to one of a cold temp., the body temp. of healthy well-nourished dogs increases several tenths of a degree during the first hrs. At the same time an av. increase of 18% was observed in the blood sugar, while no such increase was observed when their habitat was in a temp. of 22-28° in spite of a rise of several tenths of a degree in body temp. When an increase in body temp. (fever) was produced by the injection of killed colon bacilli, the blood sugar increase was parallel with that of the body temp. Accordingly the increase in blood sugar accompanying a rise in body temp. is not a result of the change in body temp. but is rather an expression of increased metabolic processes, which stand in causal connection with the chem. heat regulation.

R. C. WILLSON

**An investigation of the analysis of human milk.** BERNARD MYERS. *Brit. J. Children Diseases* 24, 249-57(1927); *Ber. ges. Physiol. expül. Pharmacol.* 45, 608.—The compn. of the milk of 86 nursing mothers was detd. Samples were in most cases drawn from only one breast. There were no definite relations between the age of the mother and the amt. of milk secretion. The ages of the mothers ranged from 16 to 30 yrs., the av. being 22 yrs. There was no relation between the per cent content of the chief constituent of the milk and the sex of the child. The av. analysis was: protein 1.58, fat 3.85 and milk sugar 6.0%. The caloric value was 18.95 per oz. (about 28 g milk). The last 1/3 of the expressed milk had the highest fat content, reaching 11.35% in 1 case. The protein content was also somewhat higher in this portion. The milk sugar showed only a slight change and the mineral content no change. There are daily variations in the amt. and compn. of human milk.

R. C. WILLSON

**The influence of the external temperature on the glycogen and fat content of the liver, and the relations of the external temperature to changes in the thyroid gland and suprarenal capsule.** T. NOSAKA. *Folia endocrinol. japon.* 3, 1558-1580(1928); *Ber. ges. Physiol. expül. Pharmacol.* 45, 630.—Rats which were kept at room temp. exhibited no microscopic or macroscopic changes in the liver; the liver contained some glycogen and fat. When kept at 2-7° the wt. and appetite increased, while the glycogen and fat were extensively reduced or completely disappeared. At a temp. of 35° or higher the appetite decreased and the body wt. either remained stationary or decreased. Together with congestion of the liver there was observed an increase in the glycogen and fat. In some cases the liver showed an inclination to destruction of its cellular nuclei

and serious fatty infiltration with an extensive decrease or complete disappearance of the glycogen.

R. C. WILLSON

**The carbohydrate metabolism in parathyroprival tetany.** J. ANDREU URRÁ AND F. QUEROL NAVAS. Fac. de med., Valladolid. *Med. iberica*. 21, 577-80(1927); *Ber. ges. Physiol. explil. Pharmacol.* 45, 524.—After the removal of the parathyroids from 3 dogs an increase in the glucemia was observed, the normal fasting values being 0.68, 0.91 and 0.95 while the later values ranged from 1.30 to 1.60. As soon as the first signs of tetany appear, the values sink to and below normal. After the convulsive attacks a hyperglucemia reappeared temporarily, the authors attributing this to the preventive reaction of the organism against the convulsions. The administration of insulin and glucose temporarily improves the symptoms. The deficiency of sugar in the blood and tissues exerts a large influence in the origin of parathyroid tetany.

R. C. WILLSON

**The influence of vegetable juices on the secretory activity of the stomach.** WITOLD ORLOWSKI. *Polskie arch. med. wewnetrznej*. 5, 66-104(1927); *Ber. ges. Physiol. explil. Pharmacol.* 45, 640.—The action of juices expressed from vegetables was studied on 20 well persons and 61 suffering with gastric maladies; the gastric contents were examined for acidity, free and combined HCl and pepsin. The abnormal subjects consisted of cases of hyperacidity, hypoacidity and achlorhydria. The acidity and N distribution in the juices of cabbage, kohl-rabi, cauliflower and potatoes were considered. The vegetable juices produced greater stimulation to the secretion of gastric juice than the Ewald-Boas test breakfast; in general they effected a higher acidity and more free and combined HCl than the test breakfast. Similar studies were carried out with dogs which had undergone the Heidenhain-Pawlow operation. Controls were fed pulp, water and oxalic acid. From the studies it is concluded that the latent time of the secretion is shorter after administration of cabbage juice and kohl-rabi juice and longer after the juices of turnips, cauliflower and potato juice than after meat. The duration of the secretion is longest after pulp (3.66 g. N), shorter by one-half after cabbage juice (0.25 g. N) and then in a descending series after turnips, potatoes, kohl-rabi and cauliflower of similar N values. The largest quantity of gastric juice was secreted following the ingestion of turnip juice, then in descending series cabbage, potato and kohl-rabi which were always above pulp (3.66 g. N). The amt. of free HCl in the secreted gastric juice after the ingestion of turnip and potato juices is 1.5 times that after pulp which is the same as after cabbage juice and larger than after kohl-rabi and cauliflower. The highest concn. of HCl was observed after potato juice. The digestive power of the gastric juice was greatest after ingestion of pulp (3.6 g. N) then follow, resp., the juice of the potato, turnip, cabbage and kohl-rabi (above-mentioned amts. of N). The action of vegetable juices on the secretion of gastric juice is to be attributed to the N-contg. extractive substance which is contained in the plants.

R. C. WILLSON

**The vagus and the secretion of adrenaline.** B. A. HOUSSAY AND E. A. MOLINELLI. Fac. de ciencias med., Buenos Aires. *Rev. soc. Argentina biol.* 3, 563-72(1927); *Ber. ges. Physiol. explil. Pharmacol.* 45, 396.—Studies were made of the effects of irritation or interruption of the vagus. They used the suprarenal-jugular vein anastomosis, in which the suprarenal vein of the donor dog is communicated with the jugular vein of the recipient dog. Weak faradic irritation of the central end of the severed vagus resulted in a slight decrease in the secretion of adrenaline which in many cases was followed by a slight increase. Stronger elec. or mech. stimulation (section or ligation of the nerve) produced a strong reflectory increase in the secretion of adrenaline. Anesthesia and subsequent section of the nerve had no effect, whereby it is proved that the vagus in a physiol. manner exerts no direct or reflectory tonic action on the secretion of adrenaline.

R. C. WILLSON

**Analysis of the effect of the osmotic pressure and of sodium chloride on the cardiac automatism.** GAETANO VIALE. *Rev. soc. Argentina biol.* 3, 621-36(1927); *Ber. ges. Physiol. explil. Pharmacol.* 45, 516; cf. *C. A.* 22, 983-4.—If the heart is steeped with NaCl soln., it begins to beat again if the concn. of the NaCl is raised quickly. Since under these circumstances an isoosmotic glucose soln. is inactive, while a more concd. one is active, it is logical to assume that the main reason lies in the change in the osmotic pressure. Changing the osmotic pressure suffices to effect the cardiac activity, as is shown by the change following the addn. of NaCl to glucose soln. or glucose to NaCl soln., either addn. causing a fatigued heart to start beating again. This effect is attained if the osmotic pressure is raised or lowered. There is assumed the rapid addn. of the washing fluid into the interior of the heart. The heart is more sensitive to the increase in osmotic pressure through NaCl than it is to the reduction through this same means. When the osmotic pressure is kept steady with glucose, the heart

functions better when the washing fluid contains a smaller amt. of NaCl; however, on account of the antagonism which exists between Na and Ca and Na and K, the heart functions better in the presence of Ca or K when the washing fluid contains a larger amt. of NaCl. In solns. in which K and Ca are equalized, the heart beats better with a little NaCl. The presence of colloids in such solns. does not influence the result.

R. C. WILLSON

**Studies of the relation of the oxidation capacity of the skin to pigmentation.** LUIGI CALIFANO AND AURELIO NASO. Univ. Naples. *Rivista patol. sper.* 2, 480-2(1927); *Ber. ges. Physiol. expil. Pharmacol.* 45, 321.—Black and non-pigmented skin (2 g. each) of the guinea pig was removed from parts of the body corresponding as closely as possible, the subcutaneous cell tissue removed, the samples were cut into small pieces and then treated with 0.02 g. *m*-nitrobenzene in 10 cc. physiol. NaCl. The intensity of the reduction at 37° was followed with the Duboscq colorimeter. The smaller the quantity of the reducing substance, the less was the dehydration capacity and the less the color intensity. The non-pigmented skin always showed a much larger capacity of reducing the nitro group than the pigmented. There was also a difference between the metabolic processes in the pigmented and non-pigmented skin.

R. C. WILLSON

**The amino acids in the blood during pregnancy, childbirth and puerperium.** A. SCOTTRINO. *Riv. ital. ginecol.* 6, 673-95(1927); *Ber. ges. Physiol. expil. Pharmacol.* 45, 539.—Usually the amt. of amino N during the puerperium is higher than during pregnancy according to S. and in opposition to the results of Falk, Hasselbach and Gammltoft. In 12 cases of albuminuria, the amino N of the blood ranged between 6.9 mg. % and 27 mg. %, the av. being 12.7 mg. %. In 6 cases of eclampsia the av. was 13.3 mg. %. The values during toxicosis are much higher than during normal pregnancy (11 mg. %). The highest values were observed in puerperal fever, the av. being 13.7 mg. %. In the pathol. puerperium more amino acids are present in the blood than in the physiol. one. All detns. were made according to Van Slyke's method.

H. GIDEON WELLS

**Fractionation of diphtheria antitoxic plasmas.** P. J. MOLONEY AND EDITH M. TAYLOR. *Colloid Symposium Monograph* 6, 109-14(1928).—The antitoxin was pptd. with alc., tannin, and Biebrich scarlet at various  $p_H$  values. Its stability was also detd. with respect to  $p_H$  and alc. Solns. of antitoxin prepd. with alc. gave, with certain serum-sensitive individuals, less reaction after intradermal injection than did solns. prepd. with  $(NH_4)_2SO_4$ .

JEROME ALEXANDER

**Genesis of diabetic hyperglucemia.** E. J. LESSER. *Klin. Wochschr.* 7, 25-26(1928). -- Polemical. The speed of glycogenolysis in the isolated frog's liver does not depend on the sugar content. Glycogenolysis is inhibited by products thereof in sufficiently high concn. An ext. of these products does not alone raise the sugar value in the liver cells, since enzyme and substrate must be brought together.

B. C. A.

**Critic of the interferometric method for the Abderhalden reaction.** A. ZIMMER, E. LENDEL AND W. FEHLow. Univ. Clinic Berlin. *Fermentforschung* 10, 396-427 (1929).—The conclusions reached are based on long experience with the Abderhalden reaction involving some 25,000 individual tests. A slight modification of the 1 mm. chamber is proposed which obviates the possibility of errors due to evapn. while taking the reading and to accidental mixing of the liquids in the 2 compartments. By the examn. of serum alone it is shown that only clear light yellow serum can be used without appreciable error. The substrates may be the cause of more or less error unless the material from which they are prepd. can be obtained anatomically pure. Errors due to adsorption and swelling are practically negligible. Concordant results from expts. with inactivated serum at various temps. up to 37° indicate that the reaction is of enzymic nature, and 24-hr. observations with active and inactive serum and active serum + charcoal in place of substrate establish this beyond a doubt. To assure at all times a uniform course of reaction it is necessary to test thoroughly all newly prepd. substrates. To establish a basis for interpretations of Abbau values of endocrine glands, 125 clinically normal glands were tested; notwithstanding different values each gland

always showed the same correlations. Normal pregnancy does not influence the Abbau picture of the endocrine glands. With brief muscular work there is a slight displacement of the curves. Even the stimulus of repeatedly taking blood samples influences the correlation somewhat. The interferometric method of the Abderhalden reaction is not technically easy of execution. There are a no. of errors arising from technic and material, but with sufficient practice these may be limited and to a large extent avoided. In the examn. of endocrine glands these errors are small, but biol. errors must here be taken into account which fortunately occur only in isolated cases. On the whole the method yields satisfactory and uniform results in the investigation of endocrine glands and warrants the study of broad clinical groups of diseases and a practical evaluation of the results.

A. W. DOX

Further studies on the enzymes occurring in blood plasma and serum with positive Abderhalden reaction, and further observations on their behavior after separation. EMIL ABDERHALDEN AND SEVERIAN BUADZE. Univ. Halle. *Fermentforschung* 10, 455-63(1929).—The Abderhalden reaction may be performed with exts. of dried serum, and thus a greater concn. of enzyme is employed than that present in the fresh serum. A neg. reaction should be verified by repeating the test with a concd. ext. of dried serum. The enzyme is not affected by heating  $\frac{1}{3}$  hr. at 60°, but at 80° it is completely inactivated. Dried serum has been preserved in sealed tubes 93 days without appreciable loss of activity. This treatment does not alter the specificity of the enzyme. In no case could a pos. reaction toward placenta protein be obtained with non-gravid serum. Glycerol and NaCl exts. of dried gravid serum were tested for trypsin content by means of chloroacetyl-L-tyrosine and titration of the CO<sub>2</sub>H in the presence of EtOH, but with neg. results. The presence of erepsin, however, was demonstrated by the increased acidity of *dl*-leucylglycine. An elution prep'd. by treatment of the Al(OH)<sub>3</sub> adsorbate of the serum ext. with (NH<sub>4</sub>)<sub>2</sub>HPO<sub>4</sub> gave a pos. reaction with placenta and a distinct cleavage of *dl*-leucylglycine. The sp. protease which attacks placenta protein is not trypsin-kinase, but it is probable that the products of hydrolysis are further broken down by the erepsin present.

A. W. DOX

The potassium, calcium and choline content of the blood following thyroidectomy in dogs. MARIA MAXIM AND C. VASILIU. *Z. ges. expil. Med.* 61, 707-9(1928).—In 6 thyroidectomized dogs a constant decrease in blood K was observed in the first 4-7 days following operation. The Ca remained unchanged for a few days and then rose. The choline increased and reached very high values during the tetanic convulsions and the respiratory crises observed.

F. L. DUNN

Studies of pathological protein destruction. III. The hexone bases and mono-aminodicarboxylic acids liberated from casein by the action of coli protease. M. SCHIERGE. Sanatorium and Kurhaus Buhlerhohe. *Z. ges. expil. Med.* 62, 141-6(1928), cf. C. A. 22, 4142.—From the residues of the Bu alc. extns. S. obtained 80 mg. of a deep blue easily sol. Cu salt by heating with CuCO<sub>3</sub>, analyses showing 24.96 and 25.36% Cu with 26.36% theoretical for C<sub>8</sub>H<sub>12</sub>N<sub>2</sub>O<sub>4</sub>Cu. From the phosphotungstic acid ppt S. obtained small quantities of histidine, arginine and lysine but not enough for analyses. The colon bacillus produces a primitive protein-splitting enzyme which has an optimum action between *p*<sub>H</sub> 6 and 7.5. Conclusion: The chem. structure of the split products of bacterial action is of great interest in the understanding of the pathology of infections.

F. L. DUNN

A physicochemical property of antitoxic and normal sera. SOPHIE KAZARNOVSKII. *Kolloid-Z.* 47, 351-7(1929).—Based on the *p*<sub>H</sub> detn. K. has shown that immune diphtheria sera become coagulated and peptized at a higher *p*<sub>H</sub> than does the normal sera. Diphtheria sera become gelatinized at a higher *p*<sub>H</sub> than does the normal sera. The expts. were conducted in the acid range.

A. L. ELDER

Bilirubinemia in malaria. M. E. WOLSKI AND E. M. SCHWELEWA. *Arch. Schiffs-Tropen-Hyg.* 33, 210-5(1929).—There is an increase of bilirubin in blood after several fever attacks. This does not occur in latent or chronic malaria.

F. K.

Serum changes in kala-azar. R. B. LLOYD AND S. N. PAUL. *Indian J. Med. Research* 16, 203-19(1928).—The formol-reacting mechanism in kala-azar is of a double nature. One factor is specific, and is assocd. with the euglobulin fraction of the serum. The other factor is non-specific. The formol gel reaction in kala-azar is analogous to a complement-fixation reaction, though the non-specific factor is not identical with complement. There is a considerable increase both in the total serum globulin and in the euglobulin fraction of kala-azar blood. This is accompanied by a decrease in serum albumin, so that the globulin albumin ratio which is normally 0.66 becomes 2.9. Treatment with Heyden 693 brings this ratio to normal in 3 weeks but the globulin pptn. is pos. and HCHO can still produce a semi-opaque gel. Strong urea soln. can prevent

the formol gel reaction and can disperse the white gel when formed. The H ion is higher and the isoelec. pt. lower in kala-azar serum. FRANCES KRASNOW

**Protein graphs in kala-azar.** R. B. LLOYD AND S. N. PAUL. *Indian J. Med. Research* 16, 529-35(1929).—The euglobulin content in kala-azar is 1.5 to 2.5 g. % (40 to 50% of total globulin) as compared with 5% of the normal. At first the total globulin and pseudo-globulin show an enormous and rapid fall while the albumin shows an equally rapid rise. Then the pseudoglobulin rises and the euglobulin falls. F. K.

**Some physicochemical changes in the blood, produced by the malarial paroxysm.** J. A. SINTON, W. B. F. ORR AND BASHIR AHMAD. *Malaria Survey of India. Indian J. Med. Research* 16, 341-5(1928).—There is a fall in surface tension and a rise in refractive index of the serum when the blood is collected at the time of the paroxysm. These changes have a distinct resemblance to those recorded during anaphylactic shock. FRANCES KRASNOW

**Studies in physical properties of different blood sera. II. Surface tension.** R. N. CHOPRA AND S. G. CHAUDHURI. *Calcutta School of Trop. Med. and Hyg. Indian J. Med. Research* 16, 447-56(1928).—Bloods from filariais, leprosy, syphilis, kala-azar and tuberculosis cases were studied. Surface tensions of sera from kala-azar and tuberculosis cases show the lowest value. The formol gel test is not accompanied by a change of  $p_H$ . FRANCES KRASNOW

**Notes on some hematological and serological investigations in leprosy.** JOHN M. HENDERSON, N. K. DE AND S. GHOSH. *Calcutta School Trop. Med. and Hyg. Indian J. Med. Research* 16, 687-94(1929).—The type and stage of leprosy appear to have little influence on surface tension, specific gravity and fragility. F. K.

**The effect of diphtheria toxin on the action of insulin. A study of the effect of infections on carbohydrate metabolism in diabetes mellitus.** R. E. NETZLEY. *Univ. of Mich. Hosp., Ann Arbor. Am. J. Diseases Children* 37, 511-28(1929).—The onset of diphtheritic intoxication in rabbits appears to be accompanied by a condition of refractoriness toward the normally hypoglycemic action of insulin. The condition may be the result of the possession of essentially antagonistic properties by the insulin and diphtheria toxin principles, since the injection of a mixt. of the 2 principles, 15 mins. after their combination, is without effect upon the blood sugar level. The hypoglycemic action of insulin upon normal animals is markedly reduced following prolonged incubation with diphtheria toxin at 37°. E. R. MAIN

**The relationship between fibrin content and sedimentation index in orthopedic cases.** ESTHER M. GREISHEIMER, MARGARET WARWICK AND MARY WALTON. *Am. J. Diseases Children* 37, 953-6(1929).—Neither the sedimentation index nor the fibrin content of the venous blood of children from 7 to 17 yrs. of age appears to be influenced appreciably by sex. Both values are significantly reduced in conditions of under-nutrition. The correlation const. between the fibrin content and the sedimentation index is  $0.757 \pm 0.041$  for the boys and  $0.714 \pm 0.047$  for the girls. A lower degree of correlation is observed in undernourished children. E. R. MAIN

**Uricemia in senility.** CARLO CURRADO. *Boll. soc. ital. biol. sper.* 4, 9-13(1929).—Thirty-seven selected individuals were tested, 36 of which were above 70 yrs. of age. Blood samples were taken in the morning, 15-16 hrs. after the last meal. Uric acid was detd. by Benedict's method. In  $\frac{2}{3}$  of the cases, the amt. of uric acid was less than 3 mg. per 100 cc. whereas in 24 young soldiers the figure was 3.30 to 4.15 mg. PETER MASUCCI

**The relation between alkaline reserve and arterial pressure in experimental post-traumatic states.** LUIGI BIANCALANA. *Boll. soc. ital. biol. sper.* 4, 19-23(1929).—Dogs were used; the traumatic shocks were produced by (1) ripping the sciatic nerves; (2) muscle bruises and fractures; and (3) evisceration and trauma of the intestine. In general, as a result of traumatic shock, there was always a marked lowering of the arterial pressure (40-65 mm. Hg); there was a corresponding drop of 10-17 units in the alk. reserve but only slight changes in the  $p_H$ . There seemed to be some parallelism between lowering of arterial pressure and lowering of alk. reserve but there was no direct relation between the 2; a low alk. reserve did not necessarily det. a lowering of arterial pressure. The injections of various amts. of acid solns. caused a lowering of the alk. reserve (10-15 units) equal to that produced by traumatic shock but the arterial pressure remained unchanged. The injections of stronger acid solns. lowered the alk. reserve further and also the  $p_H$  (7.30 to 7.00). Under these conditions the arterial pressure was lowered 35 mm. Hg; a certain form of intoxication was noted but its picture was obviously different from that of shock. Conclusion: The alk. reserve plays a part in shock but it is not a factor in hypotension. PETER MASUCCI

**The isoelectric condition of toxin-containing bouillon.** A. S. RAJESKI. *Biochem.*

Lab. Pasteur Bacteriol. Institute, Leningrad. *Biochem. Z.* 197, 8-13(1928).—The point of pptn. with max. toxicity is not to be confused with the isoelec. point of the toxin itself. The isoelec. points observed are those either of the bacillary proteins or of a combination of these with the coagulated proteins of the bouillon. S. MORGULIS

Studies on inflammation. III. Carbohydrate metabolism in the inflamed tissue during the initial stage. F. BRIKKER AND F. SUPONITZKII. Lab. pathol. Physiol. Med. Inst., Charkow. *Zhur. expil. Biol. Med.* 9, 285-90(1928).—There is more glucose in the venous blood of the inflamed rabbit ear than of the normal ear. The tissue exudate of the inflamed ear is also richer in glucose than the venous blood of the normal ear. Furthermore, the venous blood of the affected ear has a higher amylolytic index. IV. The nitrogen exchange in the initial stage. F. BRIKKER AND I. LAZARIN. *Ibid* 291-9.—The protein in the inflamed region undergoes increased catabolism, which manifests itself in an increase in the products of incomplete combustion. V. Acetone bodies in the blood of inflamed tissue. F. BRIKKER. *Ibid* 300-2.—The acetone body content of the blood flowing from the inflammatory region is generally higher than that from the normal ear. S. MORGULIS

The involvement of the kidney in diabetic coma. A contribution to the problem of the causation of coma diabeticum. I. ST. LORANT. Deutsche Univ. Prag. *Acta Med. Scand.* 70, 216-41(1929).—The idea is developed from a study of a number of cases of diabetic coma that this is due neither to a failure of the kidneys to excrete the ketone bodies nor to its failure to oxidize  $\beta$ -hydroxybutyric acid. In fact the actual kidney involvement is regarded as secondary in importance, the kidney simply suffering functionally along with all other organs in consequence of the deprivation of the cells of the essential carbohydrate. Occasionally diabetic coma is found which is not accompanied by a ketonuria, in which case there are no ketone bodies present in the blood. The way the kidney suffers is manifested first in its poor cong. capacity, but later the effect is shown more markedly in its inability to secrete water. The absence of ketone body excretion in coma is attributed to the failure of the liver to produce ketone bodies, an effect also caused by the deprivation of this organ of the physiologically all-important carbohydrate. Insulin does improve the kidney's ability to concentrate the urine, but is unable to remedy the loss of water-secreting function. Hence it happens not infrequently that the anuria occurs after the administration of the insulin. S. M.

The concept of glucosuria renalis and innocens. I. Is it at present possible to differentiate with certainty some forms of glucosuria from true diabetes? ERNST B. SALÉN AND T. NYREN. Med. Klin., Stockholm. *Acta Med. Scand.* 70, 303-29(1929).—Renal glucosuria is easily and sharply differentiated from other forms of glucosuria. The diagnosis is corroborated by the presence of a lowered kidney threshold and a normal alimentary reaction. Normal and pathological alimentary reactions are differentiated through the duration of the blood sugar rise, while the degree of rise is of no significance. Renal glucosuria is regarded as a harmless anomaly. Diabetes innocens, or benign glucosuria, is a term productive of nothing more than confusion and should be discarded. II. Definition: "Insulin refractory diabetes"; "insulin refractory group with paradoxical glucosuria"; "neurorenal diabetes." *Ibid* 330-79. The differentiation of various glucosuria forms is studied on the basis of the utilization of the insulin. The condition as "insulin-refractory" is denied any significance, and it is denied also that the fact that the insulin action does not proceed normally indicates a disturbance in the sugar metabolism, nor does the effectiveness of insulin in influencing glucosuria or the lack of its effect justify the differentiation of glucosurias into pancreatogenous and non-pancreatogenous. All forms of renal glucosuria result from a condition that sugar excretion begins at a lower than normal blood sugar concn. This varies from all hyperglucemic glucosuria forms in the presence of a normal blood sugar before breakfast, a normal duration of the loading test and a lowered threshold. However, no plausible explanation is offered to account for the fact that in some diabetics glucosuria disappears under proper insulin treatment whereas in others, no matter how much insulin is used, a certain small glucosuria always persists, except that the individuals belong to categories with high or low glucemic reactions. S. MORGULIS

Studies on iodine metabolism. III. Studies on the blood iodine level in primary thyrotoxicoses. GULBRAND LUNDE, KARL CLOSS AND O. CH. PEDERSEN. Pharmakol. Inst., Univ. Oslo. *Biochem. Z.* 206, 261-74(1929).—A sample of 5-10 cc. venous blood is introduced into 4 vols. of 96% alc. in a measuring cylinder and thoroughly mixed. The coagulum is transferred to a Soxhlet thimble and extd. for 4 hrs. on the water bath with alc. The total inorg. I is now in the alc., leaving behind the alc.-insol. fraction bound to the proteins. The alc.-sol. I can further be fractionated into the lipid-I component (sol. in  $\text{CHCl}_3$ ) and inorg. I, but the former is extremely small. The

iodine detns. are then carried out in each fraction. The normal blood I in Oslo is 11-16 %. In hyperthyreoses (primary thyreotoxicosis) the I content, and especially the org. alc-insol. fraction, is greatly increased. Administration of Lugol's solns. raises the inorg. I fraction considerably, and the org. alc-insol. fraction is at the same time greatly reduced. After a few days it becomes practically normal. The basal metabolism diminishes as the org. I decreases. In Basedows' disease the goiter is colloid and I-poor, and both increase upon treatment with I. It is considered, therefore, very probable that the alc-insol. org. fraction of the blood I is the active, I-contg. principle of the thyroid hormone. In thyreotoxicosis the blood is flooded with this org. or similar I compd. Inorg. I exerts a regulating effect on the abnormal I metabolism in cases of hyperthyreoidism, preventing a flooding of the secretory product from the thyroid gland.

S. MORGULIS

An attempt to analyze pharmacologically the metabolism of cancer. G. HECHT and F. EICHHOLTZ. Pharmacol. Lab. Farbenind., Elberfeld. *Biochem. Z.* 206, 282-9 (1929).—Numerous substances were found which have a specific inhibitory effect on the glycolysis of tumor cells, all having in common the chem. property of forming complex compds. with heavy metals. It is assumed that their inhibiting action on glycolysis is due to a reaction with a heavy metal catalyzer present in the tumor cells. Analysis shows that of all the metals investigated Cu alone is detoxicated by a previous administration of Na pyrocatechol disulfonate, glycine or alanine, if a lethal dose of the metal is given intravenously. Conclusion: Tumor cells contain a Cu catalyzer of glycolysis.

S. MORGULIS

Urine proteins in nephrosis, pregnancy and myelomatosis. LESLIE F. HEWITT. London Hospital. *Lancet* 216, 66-8(1929).—No difference could be detected, on the basis of their optical rotatory powers, between serum albumin and urinary albumin excreted in nephrosis, albuminuria of pregnancy and eclampsia. Passage of large quantities of Bence-Jones proteins through the kidney for long periods does not produce progressive kidney damage and does not cause leakage of serum albumins. Bence-Jones proteins differ in properties. It appears to be present in the serum but not in the cerebrospinal fluid. The albumin and globulin contents of the blood and cerebrospinal fluid are not abnormal in myelomatosis.

F. B. SEIBERT

Estimations of lead in tissues of lead-treated patients and animals. M. JOWETT, W. J. DILLING and W. BLAIR BELL. Univ. Liverpool and Univ. Lond. *Lancet* 216, 126-8(1929).—The method of Fairhall for detg. Pb was used. The animals were given intravenously an injection of electrically prepd. Pb colloid (about 0.5% of Pb). An hr. or two after the injection, various organs and tissues were analyzed for Pb. There is some evidence that Pb is particularly attracted to malignant tissue. The suggestion is made that very little of the Pb injected is permanently stored. The bones do not appear to retain much Pb.

F. B. SEIBERT

The interpretation of blood sugar estimations. XIX. GEORGE GRAHAM. Univ. London. *Lancet* 216, 201-2(1929).—A consideration of urine and blood sugar values in relation to diabetes, diseases of the thyroid gland, etc.

F. B. SEIBERT

Blood cholesterol during the menstrual and epileptic cycles. EDWIN GOODALL. *Lancet* 216, 384-6(1929).—The total cholesterol in whole blood was estd. by Sackett's 1925 modification of Bloor's method. The blood cholesterol was the same in the inter-menstrual as in the intra-menstrual period. In epilepsy the pre-paroxysmal cholesterol was usually slightly lower than the inter-paroxysmal value.

F. B. SEIBERT

Complementing properties of blood plasma. ROSCOE R. HYDE. *Am. J. Hyg.* 8, 859-69(1928).—From the facts that complement was demonstrated in the plasma of a person with hemophilia, that it is inherited as a simple Mendelian recessive unit, and that it is to be found in artificially prepd. (heparine) plasmas, it is concluded that complement is a natural product not derived through injury to the phagocytes.

G. H. S.

Experimental purpura with anti-platelet sera. ROSCOE R. HYDE. *Am. J. Hyg.* 8, 870-4(1928).—Guinea pigs deficient in complement develop purpura when injected with anti-guinea pig rabbit platelet serum just as do normal guinea pigs, thus suggesting that complement is not essential to the reaction. The antibody of anti-platelet serum is not of the heterophile type. Antiplatelet serum causes a destruction of platelets and purpura results, apparently from the action of this material on the capillary endothelium.

G. H. SMITH

Immunological studies of typhoid vaccination by mouth. I. Agglutinins formed in persons treated orally with triple typhoid bacterin. RACHEL E. HOFFSTADT and RANDALL L. THOMPSON. *Am. J. Hyg.* 9, 1-20(1929).—Serum agglutinins develop as readily after the oral administration of triple typhoid vaccine as after subcutaneous injection. II. Complement fixations and precipitin reactions in persons treated orally

with bile and triple typhoid bacterin. *Ibid* 21-36.—Complement-fixing antibody and precipitins are to be found in the serum after oral inoculation of triple typhoid vaccine. III. Agglutinins and complement-fixation reactions in persons treated with typhoid capsules. RACHEL E. HOFFSTADT AND CARL L. MARTIN. *Ibid* 37-46.—The reactions were of the same nature as those induced by oral inoculation of triple typhoid vaccine.

G. H. SMITH

Physical chemistry of the changes in the blood in cholesterol atherosclerosis. IGNOR REMEZOV. Staatl. Inst. in Leningrad. *Arch. ges. Physiol.* (Pflüger's) 221, 534-48(1929).—Like the hypercholesterolemia following the injection of cholesterol, that following administration by feeding is assocd. with a definite inhibition of the serum lipase. This inhibition is apparently due to a sp. reversible binding of the active principle of the blood lipase to the cholesterol. After absorption the complex is not wholly inactive, and activity is restored by the addn. of phosphates. The degree of the enzyme inhibition is detd. by the extent of the hypercholesterolemia, and the lipemia is directly related to the atherosclerosis.

G. H. SMITH

Enzyme chemistry studies in connection with hemolysis. HANS V. EULER AND EDV. BRUNUS. *Arkiv Kemi, Mineral. Geol.* 10B, No. 4, 6 pp. (1928).—A lipase prepn., of demonstrated activity upon olive oil, proved to be hemolytic for sheep cells in the absence of sensitizer and complement. The active principle is thermostable, resisting 70° for 10 mins., and is but slightly weakened by boiling. The addn. of serum to the system inhibits the action of the heat-resistant lipase prepn. but hemolysis by the active enzyme prepn. is not impaired. Sensitization of the cells with specific amboceptor does not materially modify the action of the lipase.

G. H. SMITH

Studies on "phagolysin" (antileucocytic serum). OSAMU OKITA. *Sei-i-kwai Med. J.* 47, No. 7 (Eng. abs.) 1-3(1928).—Goats injected with heterologous leucocytes (rabbit) yield an antiserum of lytic and agglutinating properties, the antibody involved being termed "phagolysin." When rabbits are injected with specific anti-rabbit phagolysin profound changes take place in the cellular elements of the blood; the red cells assume an abnormal morphology assocd. with a prompt and marked reduction in no., the white cells, particularly those of the polymorphonuclear and lymphocytic types, exhibit degenerative processes and there is a marked leucopenia. Serum changes consist in a reduction in complement content, increased mobilization of antibodies such as agglutinins, precipitins, hemolysins, amboceptors, bacteriolysins and opsonins, and an increase in the serum enzymes.

G. H. SMITH

Changes in the acid-base economy in alimentary fever and in salt fever. LUDWIG SCHÖNTHAL. *Z. Kinderheilk.* 46, 491-500.—In a child showing alimentary intoxication, the plasma was concd. with an increased Cl and diminished bicarbonate. When the water economy is disturbed by the administration of large amts. of NaCl the febrile condition is assocd. with changes in the plasma bicarbonate and in the excretion of alkali.

G. H. SMITH

Relation between tetany and water economy. H. BAAR. *Z. Kinderheilk.* 46, 502-30(1928).—The relation between mineral metabolism and hyperirritability cannot be fully explained by any hypothesis. When children with latent tetany are given equiv. amts. of different salts, with the cations or anions varied, there is a very considerable correspondence between the effects and their position in Hofmeister's series K and HPO<sub>4</sub> exert the greatest effects. Insulin and pituitrin are both tetanogenic. Diuretics, theocin in particular, are beneficial in tetany.

G. H. SMITH

Agglutination phenomena in cancer. N. WATERMAN AND L. DE KROMME. *J. Cancer Research* 13, 60-5(1929).—W. and K. confirm Freund and Kaminer's demonstration that normal serum has a lytic action upon washed cancer cells, which is not exhibited by serum from subjects of cancer. W. and K. find that the serum of some species, including adult man but not infants, contains agglutinins for tumor cells acting only when the serum is diluted and the  $p_H$  is less than 6.4. These agglutinins are not species specific and there is no difference between normal and cancerous serum.

H. G. WELLS

Paraffin not productive of cancer. HAROLD B. WOOD. *J. Cancer Research* 13, 97-102(1929).—A study of the occurrence of cancer among paraffin workers supports the exptl. evidence that pure paraffin (C<sub>21</sub>H<sub>44</sub>) is inert and not responsible for the production of cancer, which results from chem. irritants present in crude paraffin oils.

H. G. WELLS

The toxemias of pregnancy. H. J. STANDER. *Medicine* 8, 1-157(1929).—An exhaustive review, discussing the physiol. and biochem. changes of normal pregnancy, as well as pregnancy toxicoses and acute yellow atrophy of the liver. Includes bibliography of 15 pp.

H. G. WELLS

**Blood chemical studies in arterial hypertension.** RALPH H. MAJOR. Univ. Kansas, Kansas City, Kans. *Am. J. Med. Sci.* 177, 188-94(1929).—Only 6 of 154 cases of hypertension—no diabetes in the group—showed blood-sugar values in excess of 120 mg. per 100 cc. A study of 50 persons with normal blood pressures showed the normal blood guanidine value does not exceed 0.2 mg. per 100 cc. and the av. is about 0.1 mg. per 100 cc. All (15) cases of a series of chronic nephritis with hypertension showed a marked increase in blood guanidine. Eighty cases of essential hypertension were studied and 61% showed blood guanidine values higher than normal. The so-called blood guanidine was not definitely detected, but the substance present in the blood of the hypertensives gave the same color reaction as guanidine and has certain chemical properties like those shown by the guanidine bases. R. C. WILLSON

**Peptidase determinations in surgical diseases.** RUDOLF KRAFT. Univ. Graz. *Deut. Z. Chir.* 208, 126-51(1928); *Ber. ges. Physiol. exper. Pharmacol.* 47, 155.—Normal values were found after narcosis, blood transfusion without reaction, surgical tuberculosis, appendicitis without abscess, gastrointestinal ulcer and carcinoma and in severe cachexia. High values were found in suppurative processes, in the parenteral administration of protein or protein-free colloids and in thyreotoxicosis. There was no relation between the peptolytic index and fever. R. C. WILLSON

**The real chemical nature of pulmonary anthracosis.** J. PAVIOT, R. CHEVALIER AND L. REVOL. *J. méd. Lyon* 9, 615-25(1928); *J. Am. Med. Assoc.* 92, 596.—The black pigment in the lungs and sputum in chronic bronchitis and emphysema was found to be Fe pigment. R. C. WILLSON

**The action of sulfur on the general metabolism of dystrophic infants.** G. ROI. *Pratica pediatrica* 6, 373(1928); *J. Am. Med. Assoc.* 92, 938.—R. concludes that there is an abnormal elimination of S in the undernourished and atrophic child, due to altered metabolism. A state of S deficiency develops so that the processes of oxidation are much reduced, the active catalytic effects of S being absent. The oral administration of S supplies the lack of it in the protoplasm and influences favorably the capacity of the organism to assimilate food. R. C. WILLSON

**The sodium chloride content of cerebrospinal fluid in normal and pathological cases.** F. LICKINT. *Z. ges. Neurol. u. Psychiat.* 116, 348-370(1928); *J. Am. Med. Assoc.* 92, 95.—Detns. were made by the Volhard-Neubauer method. The av. normal value was 704-783 mg. per 100 cc. fluid (70 cases). In 35 cases of chronic nephritis there were 6 decreases, 15 normals and 14 increases. In eclampsia the values were nearly always normal; similar results were found in diabetes, latent syphilis (45 cases) and neurosyphilis. In tabes (8 cases) 2 cases showed a decrease. Other neurological diseases gave normal values. Low values (580-700 mg.) were found in meningitis (154 cases). R. C. WILLSON

GASSMANN, TH. *Die Beziehungen des Phosphors zum Nucleinstoffwechsel und zur Entstehung der Krebs- und Gichtkrankheit.* Bern: K. J. Wyss Erben. 23 pp. M 160.

## I—ZOÖLOGY

R. A. GORTNER

**The peroxidase reaction. XIX. Experimental production of the "striatal blood picture" in the carp by the "peroxidase puncture."** KENJI SHOJI. *Tohoku J. Exper. Med.* 11, 613-7(1928).—The "striatal blood picture" (myeloid leucocytes peroxidase-negative, but oxidase-positive) was produced by brain lesions in only 13 of 370 carp operated on. B. C. BRUNSTETTER

**Enzymic hydrolysis of keratin by the crop juice of *Astur palumbarius* (goshawk) and *Vultur monachus* (Arabian vulture).** RADENKO STANKOVIĆ, VOJISLAV ARNOVLJEVIĆ AND PETAR MATAVULJ. Univ. Belgrade. *Z. physiol. Chem.* 181, 291-9(1929).—The undigested refuse regurgitated by a hawk after having consumed a no. of sparrows showed only the quills and not the tufts of the feathers; also the beaks and claws were missing. The inference was that predatory birds are able to digest keratin. A few cc. of gastric secretion was obtained by means of a duodenal sound but not enough for enzyme studies. The gastric ejecta were therefore extd. with physiol. NaCl soln. and the filtrate was incubated with keratin in the presence of phosphate buffer of pH 8. After 24 hrs. digestion at 39° the filtrate gave an immediate reaction with Millon reagent, whereas the control tests with ext. alone and with a suspension of keratin in NaCl soln. were negative. Detns. of increase in amino N showed a partial digestion of keratin preps. from horse hoofs, human hair and sparrow claws. Heating the ext. 0.5 hr. at 95° inactivated the enzyme. Similar results were obtained with a vul-

ture that was being fed pigeons and ravens. On changing from a meat diet to a diet of unplucked birds a gradual increase in keratolytic power of the ejecta ext. was observed. The digestion of keratin is, however, more rapid in the bird's crop than *in vitro*.

A. W. DOX

The application of the metamorphosis reaction of axolotls for the standardization of the thyroid hormone. BORIS ZAVADOVSKII AND L. P. LIPCHINA. Univ. Moskau. *Z. ges. expil. Med.* 62, 27-34(1928).—See *C. A.* 22, 2637.

F. L. DUNN

The composition of the body fluids of the goosefish (*Lophius piscatorius*). HOMER W. SMITH. Bellevue Hosp., N. Y. *J. Biol. Chem.* 82, 71-5(1929).—The inorg. compn. of the spinal, pericardial and perivisceral fluids of *Lophius piscatorius* showed no consistent deviation from the compn. of the blood serum. Analyses of the serum and body fluids of *Gadus callarias*, *Spheroides maculatus*, *Amtatus calva* and *Lepidosteus osseus* are also given.

ARTHUR GROLLMAN

The effect of hydrogen-ion concentration on the sequence of protozoan forms. HUGH H. DARBY. Columbia Univ. *Arch. Protistenk.* 65, 1-37(1929).—Each organism has its own  $p_H$  range. The  $[H^+]$  effects the division rate and unfavorable  $p_H$  brings about a diminution in numbers of protozoa. Part of the rise in  $p_H$  of ponds and hay infusions is due to the urea, excreted by the protozoa and subsequently changed to  $NH_3$ . Good bibliography.

FRANCES KRASNOW

Influence of the nuclear parasites of Infusoria on metabolism. A. FIVEISKA. State Univ., Irkutsk. *Arch. Protistenk.* 65, 275-98(1929).—There is an enlargement and deformation of the nucleus with an accompanying change in its finer structures, disappearance of chromatin. The macronucleus envelops from  $1/3$  to  $3/4$  the *Paramecium* cell. Although the micronucleus contains no parasites, it nevertheless suffers change equal to those of the macronucleus. Then the nutrient vacuole circulation is interfered with and the function of the contractile vacuole is impaired as is also the general metabolism.

FRANCES KRASNOW

The role of free oxygen in development. LOUIS RAPKINE. *Compt. rend.* 188, 650-2(1929).—When fertilized eggs of *Oursin* were put in a closed tube contg. boiled sea water and a small quantity of methylene blue, they developed normally. Others treated the same, except that methylene blue was omitted, did not develop. This indicates that the principal role of O is to regulate the oxidation-reduction potential of the exterior of the cells and consequently of the interior. The establishment of a proper potential induces a special metabolism bringing about cell division.

A. L.

The low cholesterol content of the fatty matter of the chrysalides of Lepidoptera. ANDRÉE COURTOIS. *Compt. rend.* 188, 666-8(1929).—In most invertebrates the unsaponifiable part of the fatty matter is principally cholesterol. In the chrysalides of the Lepidoptera studied (*Attacus pernyi*, *Sphinx ligustri*, *Saturina pyri*) only a small percentage of it is cholesterol, and the ratio of cholesterol to fatty acids is about one-tenth the usual ratio. It is important, then, to det. both the fatty acids and the cholesterol by expt. instead of assuming that all the fatty matter, not cholesterol, is fatty acids. Otherwise, a significant amt. of other non-saponifiable matter may be missed.

AMY LEVESCONTE

The distribution of arginase in fishes. ANDREW HUNTER. Toronto Univ. *J. Biol. Chem.* 81, 505-11(1929).—"The exceptional richness in arginases of the liver, kidney, and heart of the dogfish, as previously observed, has been confirmed; and it has been made probable that this is a character common to the whole selachian subclass. The kidney and heart are as a rule much inferior in activity to the liver, and neither one shows with regularity a higher potency than the other. In contrast with the *Selachii*, the *Holocephali*, as represented by the ratfish, have livers very poor in arginase. The highest concn. of enzyme is here found in the kidney. There is some in the pancreas and possibly a trace in the heart. Among the *Teleostomi* an arginase-contg. heart appears to be a character confined to certain families. It is found, for instance, in the *Clupeidae*, the *Salmonidae*, and the *Embiotocidae*; whereas in the *Scorpenidae*, the *Hexagrammidae*, the *Cottidae*, and the *Pleuronectidae* arginase is restricted apparently to the liver and kidney."

A. P. LOTHROP

The creatine content of the muscles and some other tissues in fishes. ANDREW HUNTER. *J. Biol. Chem.* 81, 513-23(1929).—Each species of fishes shows a fairly characteristic range for the creatine content of the skeletal muscles but considerable differences exist not only between different species but even between individuals of the same species. The differences between species do not correspond in any obvious way with zoological subdivisions. In general the muscles of fish contain more creatine than those of mammals while there is a higher creatine content in the heart and testes of als. In fishes, as in mammals and birds, red muscles contain less creatine

than pale, and fetal muscle less than adult. The heart muscle of elasmobranchs contains decidedly less creatine than that of the *Teleostomi* although there is no difference in muscle creatine.

**The hemoglobin content of the blood of marine fishes.** F. G. HALL and I. E. GRAY. Duke and Tulane Univs. *J. Biol. Chem.* 81, 589-94(1929); cf. C. A. 22, 1628.—The normal hemoglobin content of the blood of 17 species of marine fishes is given. The more active species have the highest hemoglobin concn. and this is, perhaps, an index of their physiol. activity.

**The excretion of ammonia and urea by the gills of fish.** HOMER W. SMITH. N. Y. Univ. and Bellevue Hosp. Med. College. *J. Biol. Chem.* 81, 727-42(1929).—Approx. 6 to 10 times as much N is excreted by the gills of the fresh water carp and goldfish as by the kidneys. The branchial excretion consists largely of the readily diffusible substances,  $\text{NH}_3$ , urea, and amine or amine oxide derivs. while the less diffusible substances, creatine, creatinine, and uric acid, are excreted by the kidneys. The excretion of urea by the gills can unquestionably be explained by diffusion and it appears probable that the excretion of  $\text{NH}_3$  can be accounted for similarly without invoking secretory activity on the part of the gill membranes.

**The arginase law and the ureotelic nitrogen metabolism of the turtle.** A. CLEMENTI. *Boll. soc. ital. biol. sper.* 3, 938-40(1928).—The amt. of urea found in the urine of well-fed turtles in summer was 0.04-0.06%; the amt. of uric acid was too small to be detd. Under similar conditions, the urea in the urine of amphibians was 0.03-0.06%.  $(\text{NH}_4)_2\text{CO}_3$  administered to turtles by the gastrointestinal route was transformed into urea and largely eliminated through the urine. In a turtle whose av. elimination of urea was 0.05-0.06%, the amt. increased to 0.07-0.085% after the administration of  $(\text{NH}_4)_2\text{CO}_3$ . The conclusion is that the N<sub>2</sub> metabolism of the turtle is of the ureotelic type and not of the uricotelic type as in other classes of saurypsids. The presence of arginase in the liver of this type of reptile is not an exception to the arginase law but rather confirms the exactness of the law.

**The local reaction of the eggs of sea-urchin to the microscopic ray puncture of the surface.** SERGIO TCHAKHOTINE. *Boll. soc. ital. biol. sper.* 3, 989-92(1928).—The aim of these expts. was to explain certain physical-chemical phenomena which govern the permeability of the cell and especially the modifications produced after fecundation and formation of the membrane. The eggs used were those of *Paracentrotus lividus*. The eggs were punctured by ultra-violet rays for 3-4 mins. For details of the technic the original must be consulted. The ray puncture was made on unfertilized, fecundated (with membrane), and immature eggs (with nucleus). The 3 types of eggs showed different local reactions to the rays.

**Metabolism of fish retina at different temperatures.** M. NAKASHIMA. *Biochem. Z.* 204, 479-81(1929).—The metabolism of the fish retina increases with rising temp. and as this exceeds 35° aerobic glucolysis occurs to a considerable degree. However, the respiration at 37° is not low, as in the case of frog retina, and should, therefore, be able to suppress the fermentation. It follows that the Pasteur reaction must be inhibited since there is no suppression of fermentation with the rise in temp. So that the retina is an object in which according to the species, the same injury produces aerobic glucolysis either through suppression of the respiration or through suppression of the Pasteur reaction.

**The respiration of non-medullated nerves.** OTTO MEYERHOF and WALTER SCHULZ. Kaiser Wilhelm-Inst. für Biologie, Berlin-Dahlem. *Biochem. Z.* 206, 158-70(1929).—The respiration of non-medullated nerves of *Maja squinado* was compared with that of the medullated frog nerve in a state of rest and stimulation. The resting respiration of the former per g. dry substance is 10 times as great as in the latter at the same exptl. temp., and the anaerobic production of lactic acid increases in about the same ratio. The respiration of the nerves of octopoda which contain connective tissue is only  $1/2$  as great as that of *Maja* nerves. Elec. stimulation causes increased  $\text{O}_2$  consumption which outlasts the period of stimulation. If the tetany stimulation is produced for 15-min. periods with 5-10 mins. intervals, the increased respiration may last 1-2 hrs. The max. increase is frequently observed during the 15 mins. after the stimulation has ceased. From the max. values obtained with a frequency of stimulation of 10 per sec. there is a twentyfold increase in  $\text{O}_2$  consumption per g. dry substance per nerve impulse as compared to the frog ischiadic nerve.

**Lipoid content of fish organs. VI. Lipoids of herrings.** BRUNO REWALD. *Biochem. Z.* 206, 275-81(1929).—Data on the lipoid content of different parts of the herring are given.

**The nature of the calcium carbonate crystals in otoliths of *Gadus morhua*.** GUL-

BRAND LUNDE. *Pharmakol. Inst. Univ., Oslo. Biochem. Z.* 206, 436-9(1929).—The otoliths of *Gadus morrhua* contain 76.39%  $\text{CaCO}_3$ , 11.44%  $\text{CaO}$  and 11.49%  $\text{H}_2\text{O}$ , and org. substance. The  $\text{CaCO}_3$  consists of aragonite. S. MORGULIS

Notes on the chemotropic responses of certain insects. A. C. MORGAN AND S. E. CRUMB. U. S. Bur. of Entomology. *J. Econ. Entomol.* 21, 913-20(1928).—Larvae of the tomato worm (*Protoparce sexta*) fed upon 69 species of plants after they had been dipped in a steam distillate of tobacco plants or jimsonweed leaves. The untreated plants are not eaten by this insect. Sheets of paraffin impregnated with an  $\text{Et}_2\text{O}$  ext. of green tobacco leaves were fed upon freely for several days. Amyl salicylate was decidedly attractive to *P. sexta* moths, and to a no. of other species of sphinx moths. Cutworm moths (Noctuidae) were particularly attracted to fermenting fruits  $\text{EtOH}$ ,  $\text{C}_6\text{H}_5\text{NO}_2$ , artificial musk and civet were slightly attractive. Cutworm larvae were attracted to fermented corn sirup, Et acetate, Et acetoacetate,  $\text{C}_6\text{H}_5\text{NO}_2$  and vinegar; amyl butyrate and citric acid were slightly attractive. Lemon juice and peel, oil of sweet orange peel, citral, amyl nitrate, oil of sweet birch and NaCl were not attractive. A bran bait flavored with  $\text{C}_6\text{H}_5\text{NO}_2$  proved attractive to larvae of the corn root webworm (*Crambus caliginosellus*). The following compds. or mixts. were specially attractive to the insects indicated: mixt. of starch and peptone for the cigar beetle (*Lasioderma serricorne*);  $\text{NH}_3$ , acetaldehyde, isobutyl alcohol and phenylacetic acid for housefly larvae (*Musca domestica*); cinnamaldehyde, salicylaldehyde and anisaldehyde for the flower thrips (*Frankliniella tritici*) and another species of thrips (*Limothrips cerealium*); cinnamic acid, formic acid, benzaldehyde, eugenol, anisaldehyde, citral, benzoyl chloride, cinnamaldehyde and cinnamyl alcohol for bees of several species; anisaldehyde and cinnamic alcohol for the beetle, *Chauliognathus marginatus*; anisaldehyde, cinnamaldehyde and oil of anise for the beetle, *Euphora melancholica*; cinnamaldehyde and cinnamic alcohol for the spotted cucumber beetle, *Diabrotica duodecimpunctata*; cinnamic alcohol for a small fly, *Swammerdamella* sp.; anisaldehyde and cinnamaldehyde for a fly of the genus *Sciara*. Other data are given. Cf. C. A. 16, 971; 18, 3233. C. H. RICHARDSON

Esterolytic processes and duration of life of *Drosophila melanogaster*. B. SEKLA. Charles Univ., Prague. *Brit. J. Exptl. Biol.* 6, 161-6(1928).—The wild type and vestigial mutant of this fly were reared in sep. cultures. The flies were ground and the tissues extd. with  $\text{H}_2\text{O}$ . The esterolytic action of the exts. was measured by the method of P. Rona (*Abderhalden's Handb. der biol. Arbeitsmeth. Abt.* 4, 1, 547), a satd. soln. of tributyrin being used as substrate. The intensity of enzyme action is closely related to the age of the individual and to the innate potentialities of the species for duration of life. The esterolytic activity of an individual animal increases from birth until a given mean age is reached; with the advent of old age, the enzyme action declines, approximating the values for the embryo or very young individual. Enzyme action, in these expts., was markedly greater in the long-lived, wild-type fly than in the short-lived vestigial mutant. The results agree with Ruzicka's (Senescence and Rejuvenation, Prague 1926) conception of senescence: At the onset of old age, the velocity of physiol. functions decreases and there is also a decrease in total rate of metabolism. Varying longevity is due to differences in elementary physiol. processes which are hereditary. The short-lived vestigial mutant appears older than the wild-type fly even at the beginning of life. Preliminary expts. on the proteolytic activity of the exts. from the 2 types of flies showed that the proteolytic function of the vestigial flies is weaker than that of the wild type. C. H. RICHARDSON

Studies on marine wood borers. I. The toxicity of various substances on *Limnoria lignorum*. F. D. WHITE. Univ. Manitoba. *Contributions to Can. Biol. and Fisheries* 4, 1-7(1929).—Vigorous adult gribbles were transferred to crystg. dishes contg. 10 cc. of a soln. of the test compd. in fresh sea water. One individual was placed in each dish. At the end of 18 hrs. the specimens were examd. About 80 substances were tested and these can be divided into 3 groups—those lethal at 1 : 50,000; those non-lethal at the diln.; and a relatively small no. of substances whose insoly. was such that the tests were made with a fine suspension contg. 1 g. in 100,000 cc. of sea water, and which proved to be non-lethal in every case over the 18 hr. period. Org. compds. contg. tervalent As show the greatest general toxicity towards borers. II. The effect of experimental variations in salinity and  $p_{\text{H}}$  upon the wood borers of the Pacific Coast of Canada. *Ibid* 9-18. Sea water was dild. with distd. water or NaCl was added to obtain solutions having varying concns. of salinity. The  $p_{\text{H}}$  values of the solns. were adjusted by the addn. of HCl. To find the av. lethal salinity 5 vigorous adults were transferred to test jars contg. 50 cc. of soln. and examd. every 24 hrs. The  $p_{\text{H}}$  tests were carried out in a similar manner over a range of 2.5 to 9.6. The tests carried out

upon the *Limnoria* of the Pacific Coast, and contrasted with those recorded for the *Limnoria* of the Atlantic Coast, have revealed a much lower figure for 24 hr. lethal salinity (4.25 g. NaCl per l.) and a much higher critical salinity figure (17.75 g. NaCl per l.). The salinity range for full activity (estd. at 18 to 32 g. NaCl per l.) indicates that for the higher temp. of the Pacific a much higher salinity is necessary, and is further evidence that *Limnoria* can exist best under conditions of high salinity and low temp. It is suggested that while these *Limnoria* show greater individual variations, they do not appear to be able to adapt themselves to the varying hydrographic conditions of their environment, and that where low salinity and high temp. are the prevailing conditions, they carry on a precarious existence. Where the salinity factor alone is concerned, graphs have been obtained which suggest that, statistically, the survival of *Limnoria* in varying salinities can be expressed by an S-shaped curve. The variations in the  $p_H$  to which they may be exposed do not appear to be a factor of any importance, since they are unaffected over a  $p_H$  range of 4.5 to 9.6. Tests with exposed *Bankia* apparently confirm the observation that this borer resembles *Limnoria* in its reaction to conditions of low salinity.

M. H. SOULE

The decomposition of clam muscle in acid solution. CHRISTINE E. RICE. Queen's Univ. *Contributions to Can. Biol. and Fisheries* 4, 96-105(1929).—A high acidity developed in macerated clam tissues. The organisms responsible for this reaction were isolated and identified as to genera. They decompd. carbohydrates particularly glycogen with acid production when grown on lab. media.

M. H. SOULE

The iodine content of the thyroid of two species of elasmobranchs and one species of teleost. FRANCES M. BURWASH. Univ. Toronto. *Contributions to Can. Biol. and Fisheries* 4, 115-20(1929).—The skates *Raja laevis* and *R. erinacea* contain, respectively, for males 0.031 and 0.025%  $I_2$  in desiccated thyroid tissue and for females 0.048 and 0.049%. The thyroid of female haddock contains  $I_2$  in about same amts. as that of elasmobranchs.

M. H. SOULE

## 12—FOODS

F. C. BLANCK AND H. A. LEPPER

The use of 2,6-dichlorophenol indophenol as a reduction indicator in the examination of foodstuffs. J. TILLMANS, P. HIRSCH AND E. REINSHAGEN. Univ. Frankfurt a M. *Z. Unters. Lebensm.* 56, 272-92(1928).—The indicator which is obtained by coupling a soln. of 5 g. of 2,6-dichloroquinone chloroimide (the prepn. of this from  $p\text{-NO}_2\text{C}_6\text{H}_4\text{OH}$  is described) with 8 to 12 cc. of an alk. 20% soln. of phenol is very stable if stored in the form of a filtered 0.01 N (0.29%) soln. in a phosphate buffer of  $p_H$  7. The color change is from pale red to blue, between  $p_H$  4 and 5. The indicator appears deep blue in the presence of oxidizing agents and colorless with reducing agents. The reduction potential was detd. and the values at 20° against the normal H electrode were 255 and 233 mv. at  $p_H$  6.85 and 7.01. There is a fall in potential of 1 to 2 mv. for each 1° rise in temp. (C. A. 21, 29). The method was used to det. the effects of  $\text{CH}_2\text{O}$  and heat on the Schardinger reaction of milk but no definite results were obtained. Attempts to apply the method to the detn. of the nature and degree of putrefaction of meat exts. (C. A. 21, 2510) also proved ineffective. Artificial lemon juice was distinguished from the natural juice by the fact that it produced no decolorization of the indicator. The probable nature of the constituents responsible for the changes taking place is discussed.

FRANCIS P. GRIFFITHS

Interpretation of bromatological analyses. A. BRYTHIEN, C. HARTWICH AND M. KLIMMER. *Anales oficina quim. provincia* (La Plata) 1, 231-42(1928); cf. C. A. 22, 1414. Standards for the interpretation of analyses of grains, flours and dough products are given.

A. E. MEYER

The importance of hydrogen-ion concentrations in baking. H. T. S. BRITTON. *Ind. Chemist* 5, 160-3(1929).—The methods of scientific control that may be applied to baking processes on an industrial scale are reviewed. A low  $p_H$  value of the flour and dough increases the enzymic activity and the length of the fermentation period, and improves the vol., color, grain and texture of the loaves. The optimum  $p_H$  to be attained varies with the buffer content, diastatic power and gluten quality of the flour.

AMY LE VESCONTE

Cereals and their products. F. C. BLANCK, E. V. MCCOLLUM AND D. BREEZE JONES. *Am. J. Publ. Health* 19, 410-13(1929); cf. C. A. 23, 212.—Progress rept. with review of the literature.

J. A. KENNEDY

Studies in cereal chemistry. II. Basic materials. T. H. FAIRBROTHER. *Ind.*

*Chemist* 5, 153-5(1929); cf. *C. A.* 23, 2223.—The wheat milled in England comes from all parts of the world, and grading by chem. analysis is especially important. The present method of grading by bushel weight and  $H_2O$  content is being replaced by the protein content detn. Australian wheat varies from 9.17 to 16.18% in protein content. Other factors to be considered are gluten quality, ash content, maltose content and H-ion concn. The  $H_2O$  content detn. may be made in 10 mins. by distn. with xylene.

AMY LÉ VESCONTE

Composition and digestibility of maize and the by-products from its treatment for technical purposes. F. HONCAMP, W. SCHRAMM AND H. WEISSMANN. *Z. Tierzücht. Zuchtungsbiol.* 8, 265-84(1927); *Biol. Abstracts* 2, 227.—Chem. analyses and digestion trials with ethers show that white and yellow corn are essentially alike in content of total and digestible nutrients. Digestibility studies are also reported of the following by-products from corn-starch manuf.: gluten feed, gluten meal and corn-oilcake meal. The following data, calcd. to a 10% moisture basis, show the content of digestible protein and starch value, resp., expressed as kg. per 100 kg. of feed: gluten feed 19.2, 57.1; gluten meal, 43.3, 65.3; corn-oilcake meal, 16.6, 62.5.

H. L. D.

Water content of corn from the time of harvest to spring. ISTVÁN WEISER AND L. SZÉGFY. *Tierphysiol. Versuchsstta.*, Budapest. *Fortschr. Landw.* 4, 43-5(1929).—Moisture detns. were made on the grain and cobs at monthly intervals from Oct. to May for 2 seasons. Water losses are such that in spring a given wt. of ears will contain a larger proportion of grain than at harvest time.

LAWRENCE P. MILLER

A review of the Babcock test in California since 1895. W. M. RUSSELL. *Bur. Dairy Control, Calif. Dept. Agr., Mo. Bull.* 18, 207-14(1929).

C. R. FELLERS

Recent methods for the analysis of milk and their importance for the dairy industry. L. EBERLEIN. *Z. angew. Chem.* 42, 397-402(1929).—A critical discussion of the more recent chem., phys. and biological methods for the analysis of milk as published in the literature.

J. C. JURRJEIS

Microcolorimetry for milk sugar. F. GONZÁLEZ AND A. GIMENO. *Anales soc. españ. fis. quim. (tecnica)* 28, 39-47(1929).—To make the usual quant. milk-sugar detn in milk 25-50 cc. must be available, which usually is not the case. Microchem. methods were investigated; that of Folin and Wu (*C. A.* 14, 2353) for detn. of dextrose was found suitable for use with human and cow milk to an accuracy of about 1%, requiring about  $\frac{1}{4}$  hr.

E. M. SYMMES

Quality and value in cheese. L. J. LORD. *Food Manuf.* 4, 61-2, 69, 133-4, 136 (1929).—L. briefly discusses grading of cheese, the basis of quality in cheese and the practical examn. of cheese—the surface, "trying," taste and odor, texture and body and color.

J. A. KENNEDY

The examination of lard in ultra-violet light. F. WEISS. *Staat. Nahrungsm. Untersuchungsanstalt, Berlin. Z. Untersuch. Lebensm.* 56, 341-55(1928).—The behavior of a large no. of samples of lard in ultra-violet light is recorded, together with data on fluorescence and opalescence, taste, odor and behavior on standing. The effects of activated charcoal, heat, light and air and  $CO_2$  were studied. Fluorescence seemed to depend both upon the type of lard and the treatment to which it was subjected. The conclusion of Feder and Rath (*C. A.* 22, 1863) that the substance causing fluorescence is present in the unsaponifiable matter and is related to the presence of paraffin hydrocarbons is criticized and modified, since the unsaponifiable portion of fluorescent lard does not produce fluorescence when added to a non-fluorescent lard. Change in fluorescence may result from oxidation of cholesterol during heating or by the action of ultra-violet light.

FRANCIS P. GRIFFITHS

Scientific aspects of packaging and quick-freezing perishable flesh products. II. Packaging flesh products for quick-freezing. CLARENCE BIRDSEYE. *Ind. Eng. Chem.* 21, 573-6(1929); cf. *C. A.* 23, 12.—Deterioration of flesh products during freezing and transportation may be caused by desiccation, oxidation, discoloration and absorption of odors, any of which change the flavor of the product. Some of these difficulties are remedied by packaging before freezing so that compactness is obtained, and by the use of air- and moisture-proof packing material and shipping cases.

N. M. NAYLOR

When are meats spoiled? CARL R. FELLERS, ALBERT C. HUNTER AND F. A. KORFF. *Am. J. Pub. Health* 19, 389-92(1929).—Progress rept. with a review of the literature.

J. A. KENNEDY

The actual reaction at the beginning of decay of flesh. FRANZ SCHMIDT. *Arch. Hyg.* 100, 377-91(1928).—The onset of putrefaction in flesh may be detected more accurately from a consideration of electrometric measurements of  $p_H$  than by bacteriol. methods, chem. methods involving the detection of  $NH_3$ , or by cryoscopic methods. The  $p_H$  of horse flesh at death is 6.2. Detns. of the  $p_H$  of aq. exts. of the 1, kept at

various temps., indicate that meat with a  $p_H$  of 6.1 to 6.3 may be considered non-objectionable, but that meat with a  $p_H$  of 6.3, or more, is definitely spoiled. E. R. M.

**Fish meals.** I. Effect of high temperature employed for drying on the nitrogen partition. T. INGVALDSEN. *Can. Chem. Met.* 13, 97-9(1929).—The method used for detg. cystine is given in detail (Folin-Looney modified). Drying at 195° causes an increase in humin and volatile basic N, and a diminution in arginine N and cystine. The other constituents in the hydrolyzates are unaffected. Since arginine and cystine are amino acids essential to a diet, and the content in these therefore helps to det. the biological value of fish meals, heating to such a high temp. as 195° should be avoided in the prepn. of these meals. The results of the analyses are tabulated. II. Comparative analysis of meals made from non-putrid and putrid materials. *Ibid* 129-31, 139.—The results of the analysis of meals made from various species of fish and parts of fish are given in the following headings: (1) fresh material, (2) putrid fish, (3) N partition of fish meal and beef meal, (4) the same from putrid herring and putrid cod, (5) tyrosine, tryptophan and cystine content of meals made from non-putrid fish, (6) the same from putrid fish, (7) distribution of N between press cake and liquor for various fish materials, putrid and non-putrid. The protein (the factor 6.25 being used) figure for meals made from putrid material is higher than that obtained by difference (moisture, ash and ether ext. being subtracted from the total). Reasons are advanced to account for this difference. The tyrosine, tryptophan and cystine contents of the proteins of all meals made from non-putrid materials free from sperms are nearly the same. Putrefaction lowers the content of each of these amino acids; hence putrefaction should be avoided as much as possible in the prepn. of meals for feeding purposes.

E. G. R. ARDAGH

The pectin controversy. WM. CLAYTON. *Food Manuf.* 4, 137(1929). J. A. K.

Fruits, vegetables and their products. H. M. LOOMIS, C. R. FELLERS AND C. A. DARLING. *Am. J. Pub. Health* 19, 393-6(1929).—Progress rept. J. A. KENNEDY  
Grape products work at the University of California. H. B. FARLEY. *Fruit Products J. and Am. Vinegar Ind.* 8, No. 9, 8-9, 21(1929).—F. summarizes the work on some of the problems of the grape industry in the development of new grape products and new uses for existing grape products which will help to increase the consumption of Calif. grapes. J. A. KENNEDY

Beverages. T. J. KING AND MAURICE J. DOOLING. *Am. J. Pub. Health* 19, 511-2(1929).—Progress rept. and recommendations. J. A. KENNEDY

Some observations on the softening of dill pickles. M. A. JOSLYN. *Fruit Products Lab., Univ. Cal. Fruit Products J. and Am. Vinegar Ind.* 8, No. 8, 19-21; No 9, 16-17, 21(1929).—The results of a preliminary survey of the softening of dill pickles are briefly discussed. During the 1926 season an "epidemic" of softening occurred in the East Bay region of Cal.; in the season of 1927 considerable spoilage also occurred but in 1928 much less spoiling was evident. J. A. KENNEDY

Stainless steel and nickel utensils in the manufacture of pickles and sauces. H. G. ASHTON. *Food Manuf.* 4, 129-30(1929). J. A. KENNEDY

Stainless steel, aluminum and lacquered cans. E. J. NORTON. *Food Manuf.* 4, 128-30(1929). J. A. KENNEDY

The choice of metals. Is tinsplate supreme? E. W. LEWIS. *Food Manuf.* 4, 128(1929). J. A. KENNEDY

Storage of truck crops: The girasole, *Helianthus tuberosus*. HAMILTON P. TRAUB, CLIFFORD J. THOR, J. J. WILLAMAN AND R. OLIVER. *Texas Agr. Expt. Sta. and Univ. of Minn. Plant Physiology* 4, 123-34(1929).—The girasole, *Helianthus tuberosus*, is a possible com. source of fructose (*C. A.* 20, 1918). However, the tubers are subject to parasitic diseases under ordinary conditions of storage. Preliminary expts., conducted from Aug. 1927 to Mar. 1928, with the Portland variety, indicate that girasole (artichoke) tubers may be successfully stored at 32-35° F. and a relative humidity of 89-92%. This, however, may not represent the optimum conditions of storage which remain to be detd. Tubers stored at temps. above 40° F. lose moisture rapidly, shrivel and are subject to storage diseases. From maturity to the end of Jan., the ratio of fructose to glucose and of fructose to water-sol. carbohydrates decreases. A seasonal variation in the proportion of water-sol. carbohydrates extractable occurs. At the time of harvest no appreciable amts. of free reducing sugars are present. WALTER THOMAS

Poisoning produced by vetches. A. GUILLAUME. *Bull. sci. pharmacol.* 36, 226-35(1929).—Report concerning the different classes of lathyrus whose grain is used as a human and animal food, of cases of poisoning, lathyrism, and its effect on man and animals. Experiences, prophylaxis and treatment are reported. A. E. MEYER

Chemical or biological analyses of sour feeds? G. RUSCHMANN. *Inst. f. Gärungs-*

gewerbe, Berlin. *Fortschr. Landw.* 4, 233-7(1920).—It is necessary to make bacteriol. exams. as well as chem. analyses properly to evaluate fermented feeding stuffs.

Conditioning wheat or other grain. EDGAR S. MILLER (to Carrier Engineering Corp.). U. S. 1,711,574, May 7. The grain is subjected to intimate contact with air so controlled as to temp. that the temp. of the grain is approx. the same as the wet bulb temp. of the entering air and that the grain is given the desired temp. by suitable conditioning of the air. An app. is described.

Yeast food. OSCAR R. BROWN. U. S. 1,712,025, May 7. A mixt. for use as a yeast food in bread making comprises  $\text{KNO}_3$ , Ca phosphate and  $\text{MgSO}_4$  as essential ingredients, and may also include other ingredients such as NaCl and  $\text{CaSO}_4$ . A dough batch formula is given including 5 oz. of this yeast food per 196 lbs. of flour used.

Preserving soft foods. WILLIAM H. POND and LEVIS W. MINFORD. Ger. 475,019, Mar. 25, 1926. See Brit. 271,205 (C. A. 22, 1636).

Milk products. WIKTOR W. WINTER. Ger. 475,018, July 9, 1925. It is found that the compn. of the products obtainable by freezing milk, wholly or in part, and fractionally thawing the solid is dependent on the shape and surface of the vessel in which the treatment proceeds. This is illustrated by comparison of the products obtained in a frusto-conical vessel with those obtained in an inverted frusto-conical vessel.

Stabilization of milk. HENRI G. J. FOURCADE-CANCELLÉ. Fr. 651,205, Aug. 31, 1927. Milk and foods contg. it are rendered incoagulable in the stomach by the addn. of a sol. phosphate, e. g., 1 g. per l. of a phosphate of Na.

Electric sterilization of liquids such as milk. ADRIAAN H. W. ATEN and WARNER LULOFS. Fr. 651,154, Mar. 23, 1928.

Apparatus for pasteurizing milk in bulk. ERNEST A. KAESTNER and ROBERT E. KAESTNER (to J. G. Kaestner). U. S. 1,712,733, May 14.

Enriching milk and cream with peanut oil or sesame oil. H. BÜNING. Brit. 299,617, Nov. 7, 1927. The oil is "hardened to 32°" and homogenized with the milk or cream under 50-175 atm. pressure.

Butter. JOHANNES SIEDEL. Ger. 475,311, Nov. 4, 1924. Cream with 45% or more of fat is strongly cooled and churned in a vessel having an adjustable internal rotary member shaped so as to spread the cream in a uniform thin layer on the inner

surface of the vessel. The distance between the rotating surface and the wall of the vessel is increased as the operation proceeds. It is stated that sepn. into butter and buttermilk is complete after 10 mins.

**Apparatus for expressing juice from fruit.** GEORGES PELLIER. Fr. 650,498, Mar. 6, 1928.

**Preserving fruits, vegetables, etc., by enclosure in a covering of transparent hydrated cellulose applied in moist condition.** H. I. BEADLE (to Cellacote Co.). Brit. 299,392, Oct. 25, 1927.

**Treatment of raisins, etc.** THOMAS W. W. FORREST (to Sun Maid Raisin Growers of Calif.). U. S. 1,711,729, May 7. Raisins or similar fruits are subjected to intense local heating of their exterior portions while exposing them to the action of a heated vapor such as superheated, steam. An app. is described.

**Coating raisins with liquid petrolatum.** THOMAS W. W. FORREST (to Sun Maid Raisin Growers of Calif.). U. S. 1,711,728, May 7.

**Apparatus for pulping vegetable waste.** INDUSTRIAL WASTE ELIMINATORS, LTD. Fr. 650,254, Mar. 1, 1928.

**Coffee.** GEORGES WISNER. Fr. 650,938, Aug. 19, 1927. The natural aroma of coffee is preserved by a sudden chilling after roasting, or by grinding the roasted coffee while still warm with about 2.5% of melted stearic or palmitic acid, or by grinding the cold coffee with one of these acids, heating momentarily to a temp. near the m. p. of the acid, and cooling rapidly.

**"Mineral feed" for live stock.** VIRGIL R. RUPP. U. S. 1,712,404, May 7. An intimate mixt. of acid sulfate and rock phosphate is heated to form a product comprising acid phosphate with a binder of  $\text{CaSO}_4$ .

### 13—GENERAL INDUSTRIAL CHEMISTRY

HARLAN S. MINER

**Training chemists for the industries.** CHARLES A. KRAUS AND SAMUEL T. ARNOLD. *J. Chem. Education* 6, 852-7(1929). E. H.

**The Swedish chemical industry in 1928.** ANON. *Medd. Sveriges Kem. Ind.* 12, 52-79(1929).—Imports, exports and production and consumption of industrial products are tabulated. A. R. ROSE

**Volatile solvents used in industry.** ALICE HAMILTON, ELIZABETH B. BRICKER AND HENRY F. SMYTH. *Am. J. Pub. Health* 19, 523-6(1929).—The application of coatings to surfaces of all kinds is considered under 2 heads: the character of the coating, and the method of application. J. A. KENNEDY

**Calcination.** W. S. DICKIE. *Ind. Eng. Chem.* 21, 461-4(1929).—Calcining is done in processes where oxidizing is to be done, where materials are to be reduced with or without a reducing agent, where materials are to be made into new compds. by partial fusion, where materials are changed physically by heating, and in the reclamation of valuable materials from waste. The rotary *kiln* and its application to the various calcining industries are described. FRANK V. JOHNSON, JR.

**Evaporation.** PHILIP DEWOLF. *Ind. Eng. Chem.* 21, 451-6(1929).—DeWolf gives a general description of modern types of evaporators and their operation. L. A. PRIDGEON

**The trend of filtration.** ARTHUR WRIGHT. *Ind. Eng. Chem.* 21, 493-5(1929).—A résumé of the progress to date on the art of filtration is given with an indication of future developments. L. A. PRIDGEON

**The efficiency of fractionation apparatus. I. The application of F. D. Brown's rule to distillation with columns.** H. G. GRIMM. *Z. physik. Chem.* 140A, 321-41(1929).—The equation devised by F. D. Brown (*Trans. Am. Chem. Soc.* 1879, 550; 1880, 49, 304; 1881, 517) for the distn. of binary mixts. may also be applied to distn. in app. with fractionating columns, viz.  $\log \xi/L = (1 + k)[(P_1 - P_2)/P_2] \log(\eta/M)$ , wherein  $L$  and  $M$  are the initial quantities of the components  $\xi$  and  $\eta$ , the quantities of the components in the distn. flask at a given time,  $P$  and  $P_2$  are the vapor pressures of the components at the boiling temp. of the mixt., and  $k$  is an app. const. which must be detd. experimentally. EMIL KLARMANN

**Rectification.** FRIEDRICH MERKEL. *Arch. Wärmewirt.* 10, 13-7(1929).—The working of distn. columns is described with the aid of the graphical method of Ponchon (C. A. 15, 1364). ERNEST W. THIELE

**Present trends in dust recovery.** EVERETT P. PARTRIDGE. *Ind. Eng. Chem.* 21,

446-51(1929).—The various types of equipment for dust collection are classified on the basis of what can be done with the dust after removal. Dust recovery equipment has become a unit part in a number of mfg. processes.

FRANK V. JOHNSON, JR.

The chemist in the graphic industry. KAREL VNUK. *Chem. Obzor* 4, 70-6, 108-12 (112 English)(1929).—Chem. control and the role of the chemist in photochem., printing and engraving processes are described.

J. KUCERA

The excretion of lead. ROBERT A. KEHOE AND FREDERICK THAMANN. *Univ. Cincinnati. J. Am. Med. Assoc.* 92, 1418-21(1923).—Pb excreted in the faces of medical students averaged 0.08 mg. per g. ash; that in the urine was 0.08 mg. per l. Workmen with neg. or slight exposure to Pb averaged 0.10 and 0.13, resp. Workmen with moderate or severe exposure to Pb averaged 0.65 and 0.22, resp.

R. C. WILLSON

Lead poisoning in industries. THOMAS OLIVER. *J. State Med.* 37, 187-94(1929).—Miners suffer but little where the lead occurs as the sulfide, galena, which is insol.; where it occurs as the carbonate, cerussite, it has caused much illness and several deaths. The smelting process is dangerous to workmen. The improved conditions under which red and white lead are produced have reduced in  $\frac{1}{4}$  of a century the no. of cases from 377 to 15 per year. Plumbism is less prevalent among pottery workers because of the employment of a much less sol. salt of lead and to the use of a dipping bath contg. a lower content of lead. The disease has recently developed in workmen employed in wrecking old warships; the lead oxide which cements the plates together is volatilized by the oxy-acetylene flame. Painters suffer from plumbism contracted mainly from the dust breathed in while removing old paint; the introduction of a wet method for removing paint has reduced the cases materially. Plumbism is on the increase among workers on elec. accumulators.

G. H. W. LUCAS

The various cleaning processes for gases, especially for blast-furnace gases. H. ILLIES. *Feuerungstech.* 17, 1-7(1929).—A review, reproducing many details of results obtained with various installations.

ERNEST W. THIELE

Obtaining sulfur dioxide from waste gases with the aid of cyclic ketones. G. WEISSENBERGER AND L. PIATTI. *Chem.-Ztg.* 53, 245-7, 266-7(1929).—Under German law waste gases entering the atm. must not contain more than 5 g.  $\text{SO}_2$  per cu. m., whereas gases from a contact  $\text{H}_2\text{SO}_4$  plant may run 10 g. per cu. m. To remove the  $\text{SO}_2$  from the flue gas, washing with cyclohexanone and methylcyclohexanone under definite conditions of temp., concn. and time was tried, and then the soln. formed was studied to det. how it could best be broken up into its components and the recovered solvent reused in the process. The soly. of  $\text{SO}_2$  in the cycloketones depended largely upon its concn. and upon the temp. Whereas 90% of pure  $\text{SO}_2$  could be absorbed, with waste gases contg. 6.4 g.  $\text{SO}_2$  per cu. m. only about 0.5% could be taken up. The catalytic effect of metals, such as Hg, was marked.

W. C. EBAUGH

The progress of industrial heating by oil circulation. ALEXANDER B. MCKECHNIE. Parks-Cramer Co., Boston, Mass. *Ind. Eng. Chem.* 21, 496-8(1929).—The absorber, pump and piping are described. A table describes the application to industry and shows the years of service of several installations.

L. A. PRIDGON

The inflammability of insulating materials and a new apparatus for its determination. W. SCHRAMM AND W. ZEBROWSKI. *Elektrotech. Z.* 49, 601-3(1928); *Science Abstracts* 31B, 427(1928).—The inflammability of various insulating materials was detd. under operating conditions with the help of a newly developed incandescent rod app. The app. consists of an electrically heated silit rod 8 mm. in diam. and with incandescent length of 80 mm. which can be set at the temp. desired with the help of a Kurlbaum optical pyrometer, ampere meter and resistance. The advantages of silit rod as compared with metallic wire are its chem. resistance against oxidation and its high specific resistance. The rod is placed in a specially designed app. with arrangement for holding the test rod of insulating material. Tests were made for (a) inflammability, (b) loss in weight and (c) spread of flame. Values for a, b and c, are tabulated for 15 samples including cellon, bakelite and hard rubber.

M. McMAHON

New cyclic processes for refrigeration machines. HARUHISA INOKUTY. Mitsubishi Lab., Tokyo. *Z. ges. Kälte-Ind.* 36, 21-6(1929).—A theoretical discussion and exptl. data are given, including charts for  $\text{CO}_2$ .

*Effecting chemical reactions*. VEREIN FÜR CHEM. IND. A.-G. (Hans Walter, inventor). Ger. 474,283, Apr. 12, 1927. Addn. to 471,267. The method of Ger. 471,267 (C. A. 23, 2229) is modified by supplying both the reagents to one side of the porous wall and supplying to the other side a gas which may be an indifferent gas serving merely to stimulate the diffusion, or may be a reagent or a mixt. of the reagents or a gas intended to react with the initial reaction product. Thus, in prep. MeOH, CO and H may be passed through a porous tube surrounded with petr. ether vapor with which CO and (or) H may be mixed. App. for conducting the process cyclically is described.

*Purifying gases*. I. G. FARBENIND. A.-G. Fr. 650,575, Mar. 8, 1928. Gases to be used in catalytic reactions are freed from traces of water, H<sub>2</sub>S, CO, CO<sub>2</sub>, SO<sub>2</sub>, COS, etc., by treating them with reactive metals dissolved in molten salts, oxides, hydrates or metals. Examples are given.

**Purifying gases.** UNION CHIMIQUE BELGE. Fr. 650,516, Mar. 6, 1928. See Belg. 349,321 (C. A. 23, 2023).

**Drying gas.** W. C. HOLMES & Co., LTD. Fr. 650,192, Feb. 29, 1928. Gas, particularly lighting gas, is dried by passing it under pressure through a hygroscopic liquid, in the case of lighting gas at a pressure higher than the pressure in the mains. Cf. C. A. 23, 3074.

**Separating gas or gas-vapor mixtures.** METALLGES. A.-G. (Vitalis Pantenburg, inventor). Ger. 475,169, Feb. 8, 1925. See U. S. 1,702,311 (C. A. 23, 1533).

**Separating gaseous mixtures.** GESELLSCHAFT FÜR LINDE'S EISMASCHINEN A.-G. Fr. 650,314, Mar. 2, 1928.  $H_2S$  and  $CO_2$  are eliminated from gaseous mixts. by washing with water under pressure with partial recuperation of the energy contained in the water under pressure by expansion in turbines and with regeneration of the water under pressure, by washing the gas in 2 successive steps, the water under pressure being divided so that in the 1st step, the  $H_2S$  is extd. almost completely, while the main amt. of  $CO_2$  is extd. in the 2nd step and by regenerating the  $H_2S$  contg. water separately.

**Separating hydrogen from associated impurities by liquefaction of the associated substances.** I. G. FARBENIND. A.-G. Brit. 299,588, Sept. 29, 1927. Catalyst poisons,  $CH_4$ , etc., are sepd. by fractional liquefaction, the gas is washed with liquid condensate formed, and then passed through a porous material such as active charcoal, silica or alumina gel, chabasite, lignite, etc., and may be washed with alcs. or ketones in connection with the use of the condensates.

**Liquefying and separating gases.** ARTHUR SELIGMANN. Ger. 475,172, April 2, 1926. Addn. to 460,927. Ger. 460,927, which corresponds to U. S. 1,574,119 (C. A. 20, 1478), describes a method for liquefying and sepg. gases in which the total amt. of gas circulating in the app. is first cooled in counter current, then partly expanded in a machine in performing work, then further cooled in counter current, and finally completely expanded by throttling. This method is now adapted to the treatment of a plurality of gas streams of different compons. or at different pressures.

**Exothermic gas reactions.** I. G. FARBENIND. A.-G. Fr. 650,238, Mar. 1, 1928. Heat is recovered by passing the reaction gases up a winding path through the reaction chamber.

**Removing iron carbonyl from gases.** I. G. FARBENIND. A.-G. (Josef Jannek, inventor). Ger. 475,269, June 17, 1924. The gases are mixed with a reagent adapted to decomp. the  $Fe(CO)_4$ , e. g., with O, Cl, HCl or  $COCl_2$ , and the mixt is passed over a porous adsorbent such as active C or silica gel. The  $Fe_2O_3$  or other Fe compd. produced seps. on the adsorbent. Alternatively, the carbonyl-contg. gases and the reactive gas may be passed over the adsorbent in turn, the  $Fe(CO)_4$  being first adsorbed and then decompd.

**Gas masks.** SOC. CHIM. DU CAOUTCHOUC (SOC. ANON.). Fr. 651,522, Sept. 9, 1927. One or more layers of a coating formed of drying oil and cellulose acetate is applied to cloth used for protection against noxious gases.

**Filtering liquids.** SOC. ANON. DES PROCÉDÉS R. AUDUBERT. Brit. 299,448, Oct. 27, 1927. Electrical adsorption phenomena are utilized for effecting filtration under low-pressure differences. Filtration may be effected upwardly through fibrous material impregnated with electrolytic reagents, or, instead of fibers, compressed or agglomerated powdered material may be used. Asbestos, charcoal, silica, plaster or paper may be utilized for the filtration.

**Spraying liquids.** MAX KALTENBACH. Fr. 650,881, Mar. 15, 1928. In chem. reactions where a liquid is sprayed into a vessel, a glass sighthole is mounted on the dome of the vessel; it contains a U-shaped container having 2 series of holes, the lower series giving out a constant spray of liquid, the other in the form of a spiral and visible through the glass giving out a regulated amt. of liquid. The regulation is obtained by a tap lengthened by a tube dipping into the liquid in the container.

**Solidifying liquids or plastic masses.** HANS SCHEIDEMANDEL. Ger. 475,299, June 21, 1928. The manuf. of pellets, beads, strips and the like from suitable liquids or plastic masses is effected by extruding the liquid, etc., into Hg or by allowing it to flow or drop on to a Hg surface. The surface of the Hg may be covered with a hardening liquid. The process is particularly applicable to the manuf. of pellets, etc., from soap or glue.

**Evaporation.** SOC. D'EXPLOITATION D'USINES METALLURGIQUES. Fr. 651,161, Aug. 23, 1927. Liquids are evapd. especially in vacuum, in a thin stream of the order of 1 mm. thick, so as not to give to the vapor formed in contact with the heated wall, a tension appreciably higher than the pressure in the app.

**Refrigeration.** MARGARET E. HALLSTROM. Australia 13,475, May 25, 1928.

**Refrigerators.** DELCO-LIGHT Co. Fr. 651,674, Oct. 27, 1927, and Fr. 651,678, Dec. 13, 1927.

**Refrigerating machine.** SOC. ANON. POUR L'EXPLOITATION DES PROCÉDÉS MAURICE LEBLANC-VICKERS. Ger. 475,053, Feb. 3, 1926. Refrigerating machines of the type in which a refrigerant is evapd. *in vacuo* and part of the condensate returned to the evaporator, and improved means for regulating the flow of the condensate, are described.

**Refrigerating machine.** WILHELM WECKERLE. Ger. 472,400, Nov. 26, 1925, and 474,938, Jan. 13, 1927, addn. to 472,400. In refrigerating machines in which the flow of liquid to the evaporator is controlled by a float valve, the liquid is supplied to the valve chamber from a measuring vessel intermittently tilted. In Ger. 474,938, such intermittent mechanism is caused to actuate also the return flow of liquid from a separator interposed between the evaporator and the condenser.

**Multiple-stage vacuum refrigerating machine.** METALLGES. A.-G. Ger. 475,054, Jan. 22, 1924. Addn. to 453,974.

**Absorption refrigerating machines.** SIEMENS-SCHUCKERTWERKE A.-G. Ger. 475,326, Dec. 23, 1925. In the manuf. of absorption refrigerating machines operating under a pos. pressure, the final sealing of the system is effected while cooling the absorption soln. to such a degree that the excess pressure temporarily disappears.

**Refrigerating machine of the absorption type.** SACHSENWERK LICHT- UND KRAFT-A.-G. (Artur Kröner, inventor). Ger. 475,055, Dec. 8, 1927. In a continuously operating absorption refrigerating machine, the flow of liquid from the heater to the absorber is regulated by a temp.-actuated valve.

**Refrigerating system of the absorption type.** BALTZAR C. VON PLATEN, CARL G. MÜNTERS and SIGURD M. BÄCKSTRÖM (to Electrolux-Servel Corp.). U. S. 1,711,553, May 7.

**Refrigerating systems of the compression type.** RICHARD W. KRITZER (to Peerless Ice Machine Co.). U. S. 1,712,567-8, May 14. Structural features.

**Condenser for refrigerating apparatus.** THOMAS C. WHITEHEAD and FRED J. HEIDEMAN (Heideman to Whitehead). U. S. 1,713,109, May 14. Structural features.

**Insulating material.** SCHIEFERWERKE AUSDAUER A.-G. Fr. 650,442, Mar. 5, 1928. A viscous material which may be molded by pressure in the cold and hardened by heating to produce insulators is obtained by heating to boiling a mixt. of PhOH, *p*-dichlorobenzene and CH<sub>2</sub>O in the presence of NaCl, NH<sub>4</sub>Cl and hexamethylenetetramine, removing the water formed and volatile products and washing.

**Insulating materials.** SCHIEFERWERKE AUSDAUER. A.-G. Fr. 650,512, Mar. 6, 1928. Molded objects such as sheets utilizable as insulators are obtained by high pressure in the cold and heating afterwards to about 80°, of filling material such as slate, with a viscous artificial resin obtained by boiling a mixt. of PhOH, *p*-dichlorobenzene and CH<sub>2</sub>O in the presence of NaCl, NH<sub>4</sub>Cl and hexamethylenetetramine, removing the water formed and volatile compds. and washing with water. The artificial resin is about 1/6 of the wt. of filling material.

**Heat- and sound-insulation composition.** P. H. USSING. Brit. 299,266, Dec. 22, 1927. The process described in Brit. 289,830 (C. A. 23, 921) is modified by use of a soap of Zn, Mg or the like instead of an Al soap.

**Impregnating high-tension electric cable insulation or other materials with vaseline and resin, etc.** CHARLES F. COLEMAN (to F. J. Stokes Machine Co.). U. S. 1,711,774, May 7. An app. is described in which paper-wound cables may be impregnated with molten vaseline and resin mixt. which is maintained under mechanically applied pressure and in which the impregnating material is mechanically circulated in a cycle which includes a cooler external to the impregnating vessel.

## 14—WATER, SEWAGE AND SANITATION

EDWARD BARTOW

**General observations on the establishment of municipal water works.** HARTWIG KLUT. *Arch. Pharm.* 267, 268-72 (1929). W. O. E.

**Growth and operation of waterworks.** H. EIGENBRODT. *Bauing.* 1928, 609-14, 627-31, 643-7, 666-70, 721-5, 734-9; *Wasser u. Abwasser* 25, 133.—Water consumption in Germany has constantly increased since the introduction of modern waterworks. Reduction in water borne diseases has been largely due to waterworks. C. R. F.

**New Missouri River Water Works of Saint Louis.** LEONARD A. DAY. *J. Am. Water Works Assoc.* 21, 485-510 (1929).—The plant is located about 13 miles west of the

city. The present demand is about 55 m. g. d., but its ultimate capacity will be 200 m. g. d. The Mo. River can contain as high as 42 tons of mud per mill. gal., and the principal treatment is for its removal. After leaving a presedimentation basin equipped with a Dorr Clarifier, the water passes through a mixing conduit, where first milk of lime and then iron sulfate are added. After coagulation and sedimentation,  $\text{CO}_2$  is added, and a second coagulation, with aluminum sulfate, completes the treatment. Mechanical and physical details are given.

D. K. FRENCH

"Modern methods for the purification of water." G. GENIN. *Rev. gén. colloïdes* 6, 145-8, 192-7(1928).—Methods of purification are divided into 2 categories: natural and artificial. Natural processes consist in dilution of polluted water, and impounding in shallow basins. Artificial methods are numerous and are applied according to the quantity of water requiring purification and the degree of purification required. The principal methods are: sedimentation, filtration, purification by septic tanks, and the activated-sludge process. The latter method is somewhat expensive to operate but has an appreciably lower cost of installation and requires less space.

L. B. MILLER

Katadyn, a new method of water sterilization. A. THIEME. *Chem.-Ztg.* 53, 285-7(1929); cf. *C. A.* 23, 1452, 1702.—A study of the Krause patents Brit. 293,385, Fr. 643,610, which claim that Ag, Cd, Pd, Cu and other metals possess sterilizing properties for liquids placed in contact with them. The treatment of water, foods and beverages by exposure to these metals, particularly Ag, for sterilization purposes is reviewed. The containers or flasks are divided into many partitions so as to give a large contact area. The treatment may be preceded by a filtration method, the metals being used in the filter itself as an aid in sterilization. Usually several hrs. standing is necessary to destroy all bacteria. No data are presented. The app. is extensively figured.

C. R. FELLERS

Chlorophenol tastes in waters of high organic content. LOUIS B. HARRISON. *J. Am. Water Works Assoc.* 21, 542-9(1929).—Super- and de-chlorination are not satisfactory in preventing or destroying chlorophenol tastes in highly colored waters high in org. matter. In some cases, side tastes even more objectionable were created. While the ammonia-chlorine treatment in many types of water successfully overcomes Cl odors, it does not effectively prevent or destroy chlorophenol tastes. The permanganate-chlorine treatment is considered effective from all points of view. More study must be given the relation between the dose and reaction period.

D. K. FRENCH

Differentiation of boiled and raw water by means of hydrogen-ion concentration. N. KRASOVSKA-KOLOSAVA. *Zentr. ges. Hyg.* 18, 195(1928); *Wasser u. Abwasser* 25, 141.—By colorimetric H-ion detn. methods, K. was able to differentiate in 90% of the cases boiled from raw water. There is a  $p_H$  difference of approx. 0.5. Raw ground water gave 6.75, while boiled gave 7.2. Similarly, raw brook water had a  $p_H$  value of 6.62, boiled, 7.08. The  $p_H$  value of waters depends to a considerable degree upon the carbonate content.

C. R. FELLERS

Method of filtration according to Puech-Chabal. K. MILOS AND G. KARRHELA. *Zentr. ges. Hyg.* 18, 324(1928); *Wasser u. Abwasser* 25, 145.—The system consists of repeated sand filtrations, through 3 layers of sand. The diam. of the sand particles is 1-3 mm. In supplies contg. considerable Fe, the addn. of milk of lime previous to filtration proved desirable. The method proved very efficacious in removing *B. coli*.

C. R. FELLERS

Accelerated volumetric method for determination of hardness of water. I. P. ILCHENKO. *Ukrainskii Khim. Zhur.* 2, Tech. Pt. 124-6(1926).—Permanent hardness of water when detd. by the Bart-Pfeyfer volumetric method gave higher results than when detd. by a gravimetric method, due to pptn. of Fe and Al salts by the alk. mixt. of NaOH and  $\text{Na}_2\text{CO}_3$  used in the volumetric method. The magnitude of the correction is measured as follows: 500 cc. of the water sample is acidified with  $\text{HNO}_3$  and treated at 60-70° in the presence of  $\text{NH}_4\text{Cl}$  with a slight excess of  $\text{NH}_4\text{OH}$ . The ppt. is washed with hot water, dissolved in a known amount of HCl and dild. to 500 cc. A 100-cc. portion is titrated with the NaOH- $\text{Na}_2\text{CO}_3$  mixt. with methyl orange as an indicator. From this titration the value of the correction is calcd.

REA MAIZEL

Mineral water analysis reports. L. FRESSENIUS. *Z. wiss. Bäderkunde* 2, 965-8 (1928); *Wasser u. Abwasser* 25, 132; cf. *C. A.* 22, 1201.—In reporting ions present in mineral waters, F. prefers g./kg. or g./l. to the English and Intern. Soc. Med. Hydrography method of using g./100 cc.

C. R. FELLERS

The mineral waters of Bukovina. Sulfur water from Puciosu. N. D. COSTEANU AND A. COCOSINSCHI. *Bull. sect. sci. acad. roumaine* 12, 48-54(1929).—Free and combined  $\text{H}_2\text{S}$  is present.  $\text{CO}_2$  is present only in small quantities, the  $\text{HCO}_3$  ion being largely replaced by S. The water is collected in cement tanks and is extensively used for bath-

ing purposes. A typical analysis expressed in parts per 10,000 follows: total S 0.22,  $H_2S$  0.04,  $SO_2$  0.55,  $SiO_2$  0.12, total  $CO_2$  5.4,  $Al_2O_3$  0.39,  $Fe_2O_3$  0.13,  $CaO$  25,  $MgO$  0.12,  $Na_2O$  1.78,  $K_2O$  0.02,  $Cl$  0.02 and traces of  $S_2O_3$ ,  $SrO$ ,  $Mn_2O_4$ ,  $PO_4$  and  $NO_3$ . The formation of these peculiar S waters is explained by the subterranean waters highly charged with  $HCO_3$  coming in contact with sulfide ores, particularly Cu pyrite. The alkalis and alk. earth metals deposit as carbonates and the Cu pyrite is transformed into basic carbonate with the liberation of free  $H_2S$ . C. R. FELLERS

The medicaments of the salt springs and mineral baths of Greifswald. K. KEILHACK. *Geol. Centr.* (Ref.) 38, 321; *Wasser u. Abwasser* 25, 226 (1929).—The latest salt analyses show an increase over a 50-yr. period of about 10% in sol. salts.  $SrCO_3$  (0.1%) was found. This salt had not been previously reported from these waters. C. R. F.

Phosphate in boiler-water conditioning. R. E. HALL, et al. *J. Am. Water Works Assoc.* 21, 79-100 (1929).—The disadvantages of soda ash, previously suggested for boiler-water conditioning, are outlined, and phosphate, which possesses none of them, is recommended. A discussion of foaming follows, which stresses the importance of dissolved solids as a producing factor. With calcium present in the boiler water (under-treatment) the alkaline salts of tannic and a few other organic acids act as preventives of foaming; but with the calcium removed as in full treatment, they are ineffective. Many water-insol. materials with foam-repressing characteristics are mentioned and reasons given why consistent results do not follow their use. R. E. HALL

Water from Angoulême, the cause of pollution and effect on typhoid morbidity. A. L. CAPDEVILLE. *Zentr. ges. Hyg.* 18, 778 (1928); *Wasser u. Abwasser* 25, 226.—Very unsanitary conditions of sewage disposal together with an unfavorable geological situation caused a typhoid epidemic. Chlorine or "javel" sterilization of the drinking water is strongly recommended. C. R. FELLERS

Determining free moisture in sand. H. C. MCCALL. *Eng. News-Record* 102, 804 (1929).—A simple, rapid method, the accuracy of which is within the limits necessary. The amt. of sand which will balance a given wt., i. e., 1000 g., when submerged, is dried, weighed and the wt. of absorbed water detd. The sum of these wts. is a const. The amt. of free water present in any other sample is the wt. in air necessary to balance 1000 g. when submerged less the above const. R. E. THOMPSON

Bio-precipitation studies 1921-1927. A. M. BUSWELL, R. A. SHIVE AND S. L. NEAVE. Illinois State Water Survey Bull. No. 25, 93 pp. (1928) I. Aeration. A. M. BUSWELL AND S. L. NEAVE. *Ibid* 22-34.—In bubble aeration the bubbles during their ascent are surrounded by a stationary shell of water, which hinders O diffusion into the adjoining liquid. Opposing the water flow to the bubble ascent, or using suitable baffles, will decrease or rupture this water shell and hasten O absorption. Satn. of thin layers of water requires a measurable time; for satn. to occur in 0.2 sec., the film thickness must be less than 0.01 mm. By simple mech. mixing, a fairly rapid absorption of O takes place. Sewage can be clarified by such mech. devices without the use of compressed air. If mixing and sludge suspension are not dependent upon the air introduced, clarification by activated-sludge process requires less than 0.01 cu. ft. of air per hr. per gal. of sewage. Appendix to Part I. Biochemical oxygen demand experiment with small nidus tanks. *Ibid* 35-6.—II. The role of bio-precipitation in sewage treatment. R. A. SHIVE WITH A. M. BUSWELL. *Ibid* 37-81.—Bacterial growths similar to those in activated sludge removed appreciable amts. of org. matter from sewage in a nidus tank 5 ft. deep without the introduction of air other than by gentle stirring. The introduction of compressed air at a rate calcd. to supply 0.0015 cu. ft. of O per gal. of sewage, in addn. to the oxygen absorbed during gentle stirring, accelerated the growth of activated-sludge organisms. For highest efficiency it was found necessary to shake the growths from the nidus racks at intervals depending upon the detention period in the nidus tank and upon the strength of the sewage. When strong sewage was being treated at very high rates (22,000 gals. a day), it was necessary to shake each rack once in 4 hrs. With 10,000 gals. of strong sewage or less per day, it was necessary to shake the growths from the racks only once in 8 hrs. In the spring of the yr., however, the growth did not have to be removed more than once in 24 hrs., when treating less than 10,000 gals. of weak sewage per day. The foregoing expts. have shown no evidence of denitrification in the nidus tank when the sludge was removed from the racks frequently enough to prevent liquefaction, but there was an apparent loss of N when the sludge was allowed to liquefy on the racks. Straining through  $1/4''$  mesh screens and subsequent treatment in the nidus tank for a period of  $1\frac{1}{2}$  hrs. removed 85% of the suspended solids. This is 15% more than Imhoff tanks remove when treating about the same strength sewage with a detention period of 3 hrs. III. Recent experiments with nidus tank. A. M. BUSWELL. *Ibid* 82-93.—B. discusses nidus rack operating in a sedimentation tank, surface material, mechanisms for operating

wooden racks in settling tanks and cost of veneer racks, blower and rack shaker. A bibliography is appended to this series of papers. J. A. KENNEDY

Biological purification of sewage from the experience of ten years' operation (1918-28) of the treatment plant of Stuttgart. MAIER AND W. SOHLER. *Gesundh.-Ing.* 52, 261-5(1929).—Research showed that the simplest and cheapest treatment of Stuttgart sewage was with biol. filtration and that other processes as chemical pptn., aeration, ozonization, etc., in comparison, were inferior. The effluent from the sprinkling filters was always stable, odorless and clear. These filters have operated satisfactorily under severe weather conditions. WAYNE L. DENMAN

The central sewage-treatment plant of Berlin. E. WEISE. *Gesundh.-Ing.* 52, 252-8(1929).—The sewage is first passed through a sand trap in order that the sand, etc., might settle out. Air is passed through the sewage to prevent deposition of sewage materials. From the sand trap the sewage passes into the treatment plant, which is constructed along the line of two-storied Imhoff tanks. Numerous illustrations and drawings are given. WAYNE L. DENMAN

Pre-determining the extent of a sewage field in sea water. A. M. RAWN AND H. K. PALMER. Los Angeles Sanitary Dist. *Proc. Am. Soc. Civil Eng.* 55, 1167-91 (1929).—The probable area of a sewage field in sea water when the quantity of flow and the direction and depth of discharge below the ocean surface are given was detd. Exptl. tests using Eosine Y as a coloring agency were carried on in Los Angeles Harbor. The spread of dye from the discharge nozzle was detd. by actual measurement. Formulas were developed on the basis of these findings whereby the probable limits of a sewage field at any given degree of dilyn. may be detd. There was no established numerical relationship between the known or pre-detd. factors surrounding an ocean outfall outlet and the probable amt. of dilyn. obtained at the ocean surface over the outlet or of the probable spread of the field. C. R. FELLERS

The depth of sewage filters and the degree of purification. I. Studies on the relation of the depth of a sprinkling filter to the degree of purification. S. I. STRICK HOUSER WITH A. M. BUSWELL. *Illinois State Water Survey Bull.* No. 26, 5-80 (1928).—(1) The gradual evolution of sewage treatment as related to the development of the sprinkling filter is traced. (2) The theory of sewage purification in general and the various theories of the mechanism of purification by filtration are discussed. (3) A new conception of the mechanism of the purification process is proposed, based on an equilibrium between (a) the adsorption, by the film, of colloids, and sol. substances which lower the surface tension of water, and (b) the decompn. and oxidation of these substances by enzymes, bacteria, etc. Consideration of the O requirements of the film emphasized the necessity for intermittency. (4) The theoretical aspects of the relation of the depth of the filter to the degree of purification indicate that the rate of purification should decrease with depth of filter. The literature on this subject is reviewed; exptl. data support the conclusion that there is a definite depth of filter (in this case 6 ft.) beyond which the rate of purification is negligible. (5) Very deep filters cannot be dosed at rates strictly proportional to their depth because of the limiting factors of aeration, ponding and clogging. (6) The advantages of a 6-ft. filter over a 10 ft. filter of the same cubic contents, from the standpoint of most effective utilization of a given amt. of filtering medium, are pointed out. (7) The theoretical advisability of filtering through coarse medium and then through a fine medium is mentioned. There is an appendix to Pt. I contg. the analytical data and plans. A bibliography follows. II. Confirmatory data from experimental trickling filter. A. M. BUSWELL, E. L. PEARSON AND G. E. SYMONS. *Ibid.* 81-90. III. Trickling filter dosing. G. C. HABERMAYER AND H. L. WHITE. *Ibid.* 91-4. IV. Biological data on the sprinkling filter. S. L. NEAVE WITH A. M. BUSWELL. *Ibid.* 95-100. J. A. KENNEDY

Chlorination relieves ponding on sewage filter beds. FREDERICK K. WING AND ROGER C. WILLIAMS. *Eng. News-Record* 102, 621-2(1929).—The Lackawanna, N. Y., sewage treatment plant consists of Imhoff tanks and sprinkling filters. During 1928 ponding of the filters occurred due to growths of slime and accumulation of solids. Application of 32 p. p. m.  $\text{Cl}_2$  to the Imhoff tank effluent for 5 days, insuring presence of 0.5-5.0 p. p. m.  $\text{Cl}_2$  in the applied sewage, remedied the condition and restored the effectiveness of the filters, removing the slime from the stone, header pipes and spray nozzles. The cost per acre was \$110.29 with  $\text{Cl}_2$  at 6¢ per lb. Treatment during the night when the sewage is of low strength would probably be more economical. R. E. THOMPSON

Sewage prechlorination successful at Virginia Beach, Va. WM. W. WATKINS. *Bur. of Water, Norfolk, Va. Eng. News-Record* 102, 783-4(1929).—Continuous chlorination of the crude sewage entering the septic tanks was practised at Virginia Beach

during the summer of 1928. Serious odor nuisance was eliminated and it was found that prechlorination produced a tank effluent contg. no *B. coli* in 1-cc. amts. Prior to adopting prechlorination, analyses showed that  $H_2S$  increased from 2 to 4 to 15 p. p. m. during the passage of the sewage through the tanks. Insufficient  $Cl_2$  to produce residual  $Cl_2$  in the tank effluent was effective in eliminating  $H_2S$ . During the summer months, a  $Cl_2$  dosage of 20 p. p. m. was satisfactory and in cooler weather a lower dosage was effective—about 10 p. p. m. Expts. indicated that there was no advantage to be gained by splitting the  $Cl_2$  dosage between the influent and effluent. Tabulated data are included showing the  $Cl_2$  dosage, residual  $Cl_2$ ,  $H_2S$  content, total no. of bacteria and no. of *B. coli* in the influent and effluent over an extended period.

R. E. THOMPSON

**Changes of sulfur compounds during sewage treatment.** A. L. ELDER WITH A. M. BUSWELL. *Ind. Eng. Chem.* 21, 560-2(1929).—Reduction of the S content of sewage during its purification is small. Absence of obnoxious odors during treatment of sewage in ridus tanks was noted. The rate of reduction of sulfates in sewage was measured at 37°, 22° and 10°. Methods have been adapted for the detn. of various forms of S in sewage.

A. L. ELDER

**Sludge handling and utilization at the Stuttgart treatment plant.** W. SOHLER. *Gesundh.-Ing.* 52, 274-6(1929).—The sludge from the treatment plant carries about 80-85% water. Air drying reduces the water content to 60-70%. The dried sludge was formerly removed from the drying beds by hand, but today this is done mechanically. The saving resulting by mechanical handling is 0.8 marks per cu. m. This material is a good fertilizer.

WAYNE L. DENMAN

**The problem of spontaneous heating of sludge-digestion chambers.** PRÜSS. *Gesundh.-Ing.* 52, 266-8(1929).—Between 100 and 150 German heat units are spontaneously liberated from each cu. m. of sewage per day.

WAYNE L. DENMAN

**The pollution of the air by smoke.** J. S. OWENS. *Mech. World* 85, 348, 364-5 (1929).—A discussion of some aspects of the smoke-pollution problem not so familiar to engineers; the compn. of domestic soot and of London air; daylight and sunlight lost due to smoke haze; methods adopted for measuring degree of pollution of air; effect of wind velocity upon concn. of impurity; and possible remedies.

E. I. S.

**Report on dust investigations in England, the British Dominions and in America.** I. TELIKY. Labor and Health Series of Reports. *Imp. Labor J. Berlin.* No. 7(1928); *Wasser u. Abwasser* 25, 160.—This report summarizes the past 10 yrs.' researches on dust. It is concluded that 70% of the dust particles present in human lungs have a diam. of from 4 to 8  $\mu$ . Particles as large as 14  $\mu$  were rarely found. The most dangerous dust particles are the smallest ones having diams. of 0.5 to 2  $\mu$ . The relation of dust to such diseases as tuberculosis, silicosis, etc., is pointed out.

C. R. FELLERS

**The waste question in dairy plants.** O. UNGNADE. *Zentr. ges. Hyg.* 18, 220 (1928); *Wasser u. Abwasser* 25, 156.—Creamery wastes contain much nitrogenous org. matter, which readily undergoes decompn. In Norway, the whey is concd. by evapn. and used in bread making and in other foods such as cheese. Direct feeding of the fluid waste (whey) to hogs is also a means of economically disposing of the waste.

C. R. F.

**Waste disposal in the textile industry.** C. H. MÖLLERING. *Z. angew. Chem.* 42, 424 7(1929).—A popular exposition. Waste contg. much fat must be de-emulsified by mech. or chem. means before purification can be attempted. Alkalies saponify the fats, which can then be sepd. out mechanically.

C. R. FELLERS

Filtering material (U. S. pat. 1,713,250) 18.

POLLITT, ALAN A.: *The Technology of Water*. London: Ernest Benn, Ltd.

**Purifying and softening water.** HÖGANAS BILLESCHOLMS AKTIEBOLAG and DEL NORDISKE NATROLITH A. S. Fr. 650,270, Mar. 1, 1928. Base-exchange substances for purifying water are prepd. by roasting to a temp. not over 800° a clay contg. important

quantities of alkali in unstable combination, such as keupric clay of Scanie and Bornholm.

**Purification of residual waters.** AKTIESELSKABET DANSK GAERINGS INDUSTRI. Fr. 651,682, Jan. 25, 1928. A rapid and efficacious purification of residual waters is obtained by dividing the bacteriol. action of the microorganisms, according to the nature and properties of the waters to be purified, into several partially successive processes. These processes are adapted first to the principal biochem. groups of the impurities, each partial process being subdivided, if necessary, into operations corresponding to the biol. decompn. phases of the principal biochem. groups; for each of these processes or subdivisions is used a selected aerobic or anaerobic microbe, preferably obtained as a pure culture. According to the nature of the impurities the following cultures may be used, (1) proteolytic bacteria, particularly those which produce  $\text{NH}_3$ , nitrifiers and denitrifiers, (2) fat-decomposing bacteria or fungi (yeast and hyphomycetes), (3) fungi or bacteria dissolving starch or decomposing dextrin and sugar, (4) bacteria which decompose cellulose and pectin.

**Softening water.** HANS REISERT & CO. KOMM.-GES. AUF AKTIEN. Ger. 471,982 Dec. 24, 1922. The feed water for steam boilers is divided into 2 portions before feeding. One portion is treated with a basic softening agent and the other with led-back boiler water.

**Softening water.** ARTHUR ROSENHEIM. Fr. 650,265, Mar. 1, 1928. Water is softened and Fe and Mn are removed by treating it with a gel of an acid or amphoteric substance, such as silicic acid, stannic acid, titanac acid,  $\text{Al}_2\text{O}_3$ ,  $\text{Cr}_2\text{O}_3$ ,  $\text{FeO}$ , or  $\text{Fe}_2\text{O}_3$ , in the presence of basic substances such as alkalies, alkali carbonates, lime,  $\text{BaO}$ ,  $\text{SrO}$ , borates, phosphates, cyanides, silicates, aluminates, stannates, titanates, etc.  $\text{AlCl}_3$  or  $\text{FeCl}_3$  may be added to the sol and a mixed gel may be pptd. by addn. of alkali.

**Water softening.** UNITED WATER SOFTENERS, LTD. Fr. 650,720, Mar. 10, 1928. Means for automatically working the valves controlling the supply of water to be treated by base exchange substances such as zeolite are described.

**Apparatus for softening water by treatment with zeolites.** VERNON L. TANNEHILL (to Fort Wayne Engineering and Mfg. Co.). U. S. 1,713,105, May 14. Structural features of a tank, pipe and valve-control system are specified.

**Water filter.** ALEXANDRE LION and MARC HOFMAN. Fr. 651,511, Mar. 21, 1928.

## 15—SOILS, FERTILIZERS AND AGRICULTURAL POISONS

J. J. SKINNER

**Training in chemistry to meet the needs of the present agricultural situation.** HENRY G. KNIGHT. *J. Chem. Education* 6, 886-93 (1929). E. H.

**The nitrogen metabolism of the forest soil.** D. FEHER. Königl. ungar. Hochschule für Berg- und Forstingenieur. *Biochem. Z.* 207, 350-60 (1929).—The N metabolism of the forest soil has a marked periodic course. The total N content of the soil reaches a max. in June and July, diminishing rapidly in the fall until the min. is attained in September. The nitrate N generally follows the same course except that the max. comes earlier, in April and May. This again conforms more or less exactly to the curve of the total bacterial content of the soil. Much more striking is the relation between soil and air temp. curve and the N curve. No definite relationship can be traced between the N curves (total N and nitrate N) and the nitrifying and N-binding microorganisms. The relationship to the temp. indicates that the N metabolism of the forest soil is probably primarily a function of the bacterial activity. The  $\text{pH}$  and the humus content of the soil are apparently without significance. S. MORGULIS

**Leaching and decomposition of synthetic urea in natural soils with special consideration to climatic conditions.** R. BUS. Landes-Univ. Giessen. *Fortschr. Landw.* 4, 1-4 (1929).—Varying amts. of synthetic urea were added to a sandy and a loam soil exposed to weathering. Analyses for total N, ammonia N, and nitrate N were made every 14 days. Results agree with those of other investigators (cf. C. A. 19, 1748).

LAWRENCE P. MILLER

**The physical analysis of soils.** E. ROUX, G. JORET and L. COUDERC. *Compt. rend. acad. agr. France* 15, 521-6 (1929).—A new method of mech. analysis is as follows: treat 20 g. of soil, previously freed of org. matter by  $\text{H}_2\text{O}_2$  (in the case only where the soil is rich in humic material), with  $\text{N HCl}$  sufficient to decompose the carbonates, then with

250 cc. of 0.2 N HCl; after contact for 1 hr. with frequent agitation pour on to a filter, wash first with 0.2 N HCl, then many times with distd. H<sub>2</sub>O for removing HCl; after which place the soil in a flask with 500 cc. of H<sub>2</sub>O contg. 1 g. of pure NaOH and agitate for 2 hrs.; then transfer to a large-necked flask, and sep. the following elements: clay, silt, fine sand and coarse sand. This method giving nearly the total clay permits of a better comparison of the soils. The new method permits from the point of view of the clayey colloids a clearer distinction between the different silty soils of the Somme. Its value is again evident when one detcs. the coeff. and curves of satn. (according to the definition and technic of Brioux and Pien); these coeffs. are much more comparable between themselves (for soils evidently poor in humus). The variations of the silty fraction detd. by the new method are almost parallel to those of clay and distinguish clearly the different silty soils of the Somme. For the fine and coarse sand the values obtained by the former method and the new method are very different. E. F. S.

Physical and chemical investigations on Danish heath soils (podsoils), especially as to their colloid and nitrogen content. FR. WEIS. *Kgl. Danske Videnskab. Selskab. Biol. Medd.* 7, No. 9, 148 pp. (1929); (résumé in English, 48 pp.).—The heath soils investigated, the profiles opened and the methods used in the lab. investigations of the soil samples are described. The following detns. were made:  $p_H$  value, hygroscopic H<sub>2</sub>O, humus (C in org. compds.), inorg. colloids (SiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>) total N, NH<sub>3</sub> and nitrate N, chemically bound H<sub>2</sub>O, SiO<sub>2</sub>, TiO<sub>2</sub>, Al<sub>2</sub>O<sub>3</sub>, Fe<sub>2</sub>O<sub>3</sub>, CaO, MgO, Mn<sub>2</sub>O<sub>4</sub>, Na<sub>2</sub>O, K<sub>2</sub>O, P<sub>2</sub>O<sub>5</sub>, SO<sub>3</sub> and CO<sub>2</sub>. An attempt was made to characterize the sep. types of soil in order to classify them so that their practical valuation might rest on scientific methods of investigation. The present analyses are considered suitable for illustrating some of the most important phys. and chem. characters of the soils, which, in turn, are detg. factors for their biol. characteristics. The single groups of detns. are first studied separately and later in their mutual relation. E. F. SNYDER

The occurrence of podsol soils in Quebec Province. R. R. McKIBBIN. Macdonald Coll., Quebec, Canada. *Science* 69, 501-2 (1929).—Work with Quebec surface soils and subsoils has shown a prevalence of the podsol type in certain districts. A table is given showing the characteristics of the Quebec podsol soils studied. E. F. S.

Determination of the quantity of carbon and constitutional water contained in the soils of the earth. V. AGAFONOFF. *Compt. rend.* 188, 1000-1 (1929).—From the table given the soil type most developed is the podsol; the lateritic soils are next (by considering the soils of the lowlands and the soils of the mountains as very heterogeneous and poorly studied), the famous chernozem only taking fourth place. The total amt. of C contained in the soils of the earth is only the 10<sup>-8</sup> part of the C of the earth's surface (10<sup>16</sup>). The enormous concn. in constitutional H<sub>2</sub>O of the lateritic soils makes the total quantity of this H<sub>2</sub>O 17 times greater than the quantity of C. It is evident then that complete chemico-phys. analyses of all the zonal soils will lead to geochem. findings of the greatest importance. E. F. SNYDER

The determination of the lime needs of soils. FRANZ WOHACK. Landw. Chem. Bundesversuchsanstalt, Linz. *Fortschr. Landw.* 4, 239-40 (1929).—A modification of the Gehring-Wehrmann method (*C. A.* 22, 294), consisting essentially in a shortening of the procedure by using smaller samples, is suggested. LAWRENCE P. MILLER

Experiences with the determination of the nutrient needs and the inoculability of soils with the *Azotobacter* method of Niklas. LUDWIG VON KREYBIG. *Fortschr. Landw.* 4, 12-7 (1929).—This is a general discussion of the importance of the biology of the soil and of biological methods in nutrient evaluations. The relations between the soil reaction and the *Azotobacter* development and P fertilization and the importance of the *Azotobacter* in the soil are emphasized. LAWRENCE P. MILLER

Comparison of Mitscherlich's and Neubauer's methods for determining nutrient content of soils. H. WIESSMANN AND E. SCHRAMM. *Z. Pflanzenernähr. Düngung* 3B, 105-28 (1929).—In the Mitscherlich method for the potash value the sum of potash in grain and straw should be taken. In potash-deficient soils the grain yield is reduced more than the straw. Of 115 soils of various origins the Mitscherlich method usually gave values only one-half that of the Neubauer method, but the P<sub>2</sub>O<sub>5</sub> was 47-80% higher. Little agreement exists between the two methods. However, soils which are poor or rich, resp., by one method usually show a tendency in the same direction by the other. The results of the authors are in accord with Neubauer's results. Heating of the soils does not cause better agreement between the two methods. Soils low in plant nutrients usually gave lower  $p_H$  values. H. B. SIEMS

Rapid methods for the determination of the phosphorus requirements of soils. F. SCHEFFER. Inst. f. Pflanzenbau, Univ. Halle. *Fortschr. Landw.* 4, 37-40 (1929).—In the *Azotobacter* method of Niklas (*C. A.* 19, 1610) it is often difficult to est. the growth

of the *Azotobacter* because of the presence of foreign organisms. High results sometimes occur since these organisms cause the formation of acids which dissolve some P which would otherwise be unavailable. The substitution of Ca acetate for mannitol in the nutrient soln. gives purer cultures and the results are in good agreement with those given by the Neubauer and Mitscherlich methods. A method introduced by S. (Landw. Jahrb. 67, 779) consists in shaking 30 g. of soil with 1 g. of  $\text{CaCO}_3$  in 75 cc. of  $\text{H}_2\text{O}$  satd. with  $\text{CO}_2$ , on a rotating machine for 1 hr. and detg. the P in the filtrate by the method of Wrangell (C. A. 21, 2857). Results compare favorably with those of other methods.

LAWRENCE P. MILLER

The phosphoric acid requirement of soils and its determination by the *Azotobacter* method of Christensen-Niklas. A. H. ERDENBRECHER. *Centr. Zuckerind.* 35, 885-8 (1927).—Although the *Azotobacter* method must be considered more as a qual. test by means of which soils poor in  $\text{P}_2\text{O}_5$  can be sepd. from those which are not deficient in  $\text{P}_2\text{O}_5$ , nevertheless it is, by reason of the quantity of the material to be handled, superior to the quant. methods. In this case the quantity is the deciding factor. It is to be hoped, therefore, that by the utilization of the knowledge gained by the *Azotobacter* method crop failures attributable to  $\text{P}_2\text{O}_5$  deficiency can be avoided. E. F. SNYDER

Phosphoric acid and lime content of Oldenburg soils. S. GERICKE. *Z. Pflanzenernähr. Düngung* 1B, 1-14(1929).—Most Oldenburg (Germany) soils have high lime and phosphorus requirements. Without lime, neither phosphorus nor potash produces any marked crop response. During 1926-27 38.6% of the soils show  $\text{pH}$  4.0-4.5; 23.6%,  $\text{pH}$  5.0-6.0; 37.8%,  $\text{pH}$  6.5-7.5.

H. B. SIEMS

Determination of plant food content of soils through pot experiments. HANS WIESSMANN. *Z. Pflanzenernähr. Düngung* 2B, 76-89(1929); cf. C. A. 22, 2425.—Plants are able to utilize 20% of easily sol. phosphates in the soil during the growing period; hence the  $\text{P}_2\text{O}_5$  content of soils should be five times as much as is required by each crop. W. used mixtures of sand, soil to be tested and various plant nutrients to det. the state of fertility of soils with respect to phosphorus and potash.

H. B. SIEMS

The utilization of nitrogenous mineral fertilizers by crops. DEMOLON. *Compt. rend. acad. agr. France* 15, 527-32(1929).—The ratio (N recovered:N applied)  $\times$  100 represents the coeff. of utilization. For a given soil, the coeff. of utilization for large amts. of N is always much higher in pot expts. than in field tests. The coeff. calcd. as above may be greater than 100. This is observed only with small quantities of N and principally for the cereals. The coeff. of utilization varies in wide limits, in a parallel manner to the increases in yields obtained per kg. of N. The use of nitrogenous fertilizers allows of a very variable utilization of N by crops, and the possibility of important losses. A table is given showing the coeff. of utilization for wheat, sugar beets, potatoes, oats and barley.

E. F. SNYDER

Investigations of the bacteria content and action of differently treated stable manures with special regard to "processed" manure prepared by the process of H. Krantz. WALTER GOETERS. *Landw. Vers. Sta.* 108, 1-60(1929).—The total bacteria content of the stable manure was reduced as well by very high as by very low temps. (60-80° and 0°, resp.). The greatest increase was observed at 20° and at 40°. The development of the cellulose-decomp. bacteria shows in processed manure a non-uniform course, according as they grow anaerobically or aerobically. The anaerobic cellulose decomposers are slightly resistant against high temps. Only a small portion of these organisms was still capable of living at higher temps. The aerobic cellulose decomposers thrive only at temps. under 38-40°. The increase in yield in pot expts. was about 2 to 4 times greater in pots fertilized with processed manure than in those fertilized with farm manure. The increase in gross returns obtained from farm and processed manure stood in the ratio of 1:2.3 and 1:3.8, resp.

E. F. SNYDER

Chemical and microbiological principles underlying the transformation of organic matter in the preparation of artificial manures. SELMAN A. WAKSMAN, FLORENCE G. TENNEY AND ROBERT A. DIEHM. New Jersey Agr. Expt. Sta. *J. Am. Soc. Agron.* 21, 533-46(1929).—The problems involved in the study of the principles underlying the decompn. of mature straw and other plant residues in composts leading to the formation of so-called artificial manure involve a knowledge of (a) the compn. of the plant material, (b) mechanism of the decompn. processes which are brought about by the microorganisms, and (c) a knowledge of the metabolism of these organisms. Straw and other farm residues that are commonly used for composting consist predominantly (60% or more) of celluloses and hemicelluloses which undergo rapid decompn. in the presence of sufficient N and other minerals; of lignins (15 to 20%) which are more resistant to decompn. and which gradually accumulate; of water-sol. substances (5 to 12%), which decomp.

very rapidly; of proteins which are usually present in very small amts. (1.2 to 3.0%) but which gradually increase in concn. with the advance of decompn.; and of the mineral portion or ash. The processes of decompn. involved in the composting consist largely in the disappearance of the celluloses and hemicelluloses. These polysaccharides cannot be used as direct sources of energy by N-fixing bacteria; their decompn. depends entirely upon the action of various fungi and aerobic bacteria. In the decompn. of the celluloses and hemicelluloses, the microorganisms bring about the syntheses of microbial cell substance. Frequently this may be equiv. to a fifth or more of the actual org. matter decompd. To synthesize these large quantities of org. matter the microorganisms require large quantities of available N and  $P_2O_5$  and a favorable reaction. As the plant residues used in the prepn. of "artificial manure" are poor in N, available inorg. N must be introduced for the purpose of bringing about active decompn. In general, artificial composts can be prepd. from plant residues of any chem. compn. so long as the nature of these residues and of the processes involved in their decompn. are known. By regulating the temp. and moisture content and by introducing the required amts. of N,  $P_2O_5$ ,  $K_2O$  and  $CaCO_3$ , the speed of decompn. and the nature of the product formed can be controlled.

E. F. SNYDER

**The substitution of stable manure by fertilizers, green manures and peat. III.** BURT L. HARTWELL AND F. K. CRANDALL. Rhode Island Agr. Expt. Sta., *Bull.* 216, 1-20(1928).—Twelve-yr. rotation expts. are summarized. Cabbage following late celery gave yields unrelated to the form of org. matter present. Manure materially increased the yields of tomatoes and celery. On the peat plots, even after neutralization of the acidity, only the acid-tolerant plants, cabbage and tomatoes, made satisfactory growths. Under manure, lettuce responded best to very high  $P_2O_5$ , celery to high  $P_2O_5$  and N, while beets, cabbage, tomatoes and spinach required large addns. of N. Chlorosis, because of lack of Mn, developed in some crops. Oats, spinach, beets and lettuce benefited from applications of 8 lbs. per acre of  $MnCl_2$ . Tomatoes, celery and cabbage derived no benefit from the Mn. A nitrate level of 10 p. m. in the soil delayed maturity in some crops but increased the total yield over plots having a lower N level.

C. R. FELLERS

**The action of nitrogen-containing fertilizers.** HASSELHOFF. *Z. Pflanzenernähr. Düngung* 3B, 136-42(1929).—A general discussion of crop response to various synthetic nitrogen fertilizers.

H. B. SIEMS

**Action of various nitrogen-containing fertilizers.** GERLACH. *Z. Pflanzenernähr. Düngung* 2B, 89-91(1929).—Tests made in 1913 with rye show that  $NaNO_3$  and  $Ca(NO_3)_2$  give practically the same crop response. Iodine in Chile saltpeter did not increase the yields as compared with synthetic  $NaNO_3$ . During 1916 and 1917, various synthetic nitrogen fertilizers all gave good results with beets and potatoes.

H. B. SIEMS

**Basis for correct use and good crop response of important nitrogen-containing fertilizers.** O. ENGELS. *Z. Pflanzenernähr. Düngung* 2B, 49-61(1929).—Chile saltpeter, synthetic sodium nitrate and calcium nitrate physiologically react alkaline and are recommended for acid soils such as high peat lands and light mineral soils.  $NaNO_3$  on heavy soils causes formation of a crust, but  $Ca(NO_3)_2$  does not. Fall application of nitrates for winter wheat, etc., is not recommended. Nitrates are best applied early in the spring before growth starts. For winter cereals  $NH_3$ -contg. fertilizers are recommended. Heavy nitrate application may cause lodging and disease attacks. All cereals and sugar beets respond well to nitrate nitrogen. Leafy truck crops such as spinach, etc., prefer the nitrate form. Nitrate nitrogen is not recommended for the best results for potatoes, onions, cucumbers and celery. Tomatoes may become watery and have their flavor impaired by nitrates. Ammonium sulfate is a physiologically acid-reacting fertilizer and should not be used on acid soils without lime, etc. It gives the best results on heavier soils contg. calcium and poorer response on very sandy soils. Conditions should be favorable for nitrification. Colloids in very heavy soils may compete with plants for ammonia and bacteria may convert it into proteins unavailable for plant use. It should not be plowed under with fresh manure. Potatoes, tobacco, etc., prefer ammonia nitrogen. Cyanamide is a chemically and physiologically alkaline-reacting fertilizer. It is not suitable for use on all soil types and should not be used as top dressing. Soils with a high base-exchange capacity give fairly good crop response with cyanamide. Urea reacts physiologically neutral. Tobacco and truck crops have shown particularly good results with urea.

H. B. SIEMS

**A contribution to the saltpeter question.** K. NEHRING. Albertus Univ., Königsberg. *Fortschr. Landw.* 4, 40-2(1929).—Pot investigations with oats using saltpeter from various sources failed to show any appreciable differences. The addn. of small

quantities of KI to pots in which German saltpeter was used did not increase the yields above exptl. error.

LAWRENCE P. MILLER

**Toxicity differences among the common arsenicals.** LEOPOLD FULMEK. *Forstsch. Landw.* 4, 209-12(1929).—Arsenites and arsenates were mixed with talc in such proportions that the arsenites contained 30%  $As_2O_3$  and the arsenates, 30%  $As_2O_5$ . The powders were dusted on leaves and the toxicity against the beetles of *Phyllobius oblongus* L. and the caterpillars of *Orgyia antiqua*, *Gastropacha quercifolia*, and *Pieris brassicae* was detd. The order of toxicity for the arsenites was  $Mg > Cu, Ca, Pb > Fe > Zn$ ; for the arsenates,  $Pb > Cu > Ca > Mg > Zn > Fe$ . The arsenites were more effective than the arsenates except that Pb arsenate was equal to Zn arsenite. A detn. of the water-sol. As in the preps. showed no relation between this and the toxicity. The order of soly. in a buffer mixt. consisting of 280 cc. water, 2 cc. 0.1 N NaOH and 18 cc. glycine,  $pH$  about 9 [the intestinal juice of the caterpillar of *Bombyx mori* has been reported to have a  $pH$  of 9.0-9.8] agreed with few exceptions with the toxicity. LAWRENCE P. MILLER

**The role of Bordeaux mixture as a leafhopper insecticide.** DWIGHT M. DELONG. U. S. Bur. of Entomol., Columbus, Ohio. *J. Econ. Entomol.* 22, 345-53(1929).—Pyrethrum exts. have an immediate toxic action upon the potato leafhopper (*Empoasca fabae*) but do not affect those that hatch a few hrs. after the treatment. Leafhoppers which feed on plants treated with Bordeaux mixt. show no decrease in population during the first 24 hrs., but in 3-4 days none remains alive. Bordeaux mixt. does not kill leafhoppers when they are wetted with it. Expts. showed that the Cu in Bordeaux mixt. is absorbed by the plant and it is inferred that the leafhoppers obtain Cu in some form from the cell sap. C. H. RICHARDSON

**Insecticidal tests with oils and alkaloids of larkspur (Delphinium consolida) and stavesacre (Delphinium staphisagria).** W. M. DAVIDSON. U. S. Food, Drug and Insecticide Administration, Washington, D. C. *J. Econ. Entomol.* 22, 226-34(1929).—Soap emulsions of larkspur and stavesacre oils were effective against red spiders (*Tetranychus telarius*), various species of aphids, Colorado potato beetle larvae (*Leptinotarsa decemlineata*), larvae of the imported cabbage worm (*Pieris rapae*), and cross-striped cabbage worm (*Evergestis rimosalis*) and sow-bugs (*Isopoda*). Young larvae of the greenhouse white-fly (*Trialeurodes vaporariorum*) were killed whereas the other stages proved resistant to a 2% emulsion. The same concn. killed Calif. red scale (*Chrysomphalus aurantii*) in the greenhouse and was of lesser value against San Jose scale (*Aspidiotus perniciosus*) in the field. Two % emulsions injured some plants (beans, sweet cherry, rose, hollihock) but not deciduous trees. The alkaloids, delcosine, delsoline and delphinine (0.042 and 0.085%), in soap solns. were toxic as contact and stomach poisons to a variety of insects. Delphinine-HCl (up to 0.16% alkaloid) was inefficient against the green peach aphid (*Myzus persicae*), mealy bugs, red spiders, *Heliothrips femoralis* and the fall webworm (*Hyphentria cunea*). A 0.085% soln. killed the onion thrips (*Thrips tabaci*) and larvae of *Pieris rapae*. The alkaloids did not generally injure foliage at the concns. used. C. H. RICHARDSON

**Effect on young rice plants of adding aluminum salts to complete culture solutions.** FELIX VILLA. Univ. of Philippines, Los Baños. *Philippine Agr.* 17, 607-25(1929).— $Al_2(SO_4)_3$  and  $Al(NO_3)_3$  were about equally toxic to rice plants in 0.00025, 0.0005 and 0.00075 molar soln. The same proportion of Al in soln. produced more injury in incomplete culture solns. than in complete nutrient media. In concns. of 3, 5 and 8 p. p. m. Al stimulated growth in height but injured rice plants as measured by the dry wt of root and tops. Nine references are given. A. L. MEHRING

**Fumigation with calcium cyanide for the control of the greater and lesser bulb flies.** F. R. COLLE. U. S. Bur. of Entomol., Santa Cruz, Calif. *J. Econ. Entomol.* 22, 236-7(1929).—Finely ground Ca cyanide, 12 oz. per 100 cu. ft., is successfully used to kill larvae of the narcissus bulb fly (greater bulb fly) (*Merodon equestris*) and the lesser bulb fly (*Eumerus strigatus*) in narcissus and daffodil bulbs. The exposure time is 4 hrs. App. is described. C. H. RICHARDSON

**Care of walnut stock before and after vacuum fumigation.** D. B. MACKIE and A. H. CALL. Calif. Dept. Agr., *Mo. Bull.* 18, 218-20(1929).—HCN gas, 18 cc. HCN per 100 cu. ft., is used in vacuum fumigation of nursery stock for red-scale destruction. The contact period is 1 hr. Injury to the vitality of the stock occurred unless the trees were in a dormant condition when fumigated. Few new rootlets should be present, as injury to the roots is most severe. Roots should be protected by burlap or sawdust. After fumigation the stock should be thoroughly sprinkled with water and kept in the shade. C. R. FELLERS

**The purity of commercial o-dichlorobenzene.** J. WM. LIPP. U. S. Bur. of Entomology, Moorestown, N. J. *J. Econ. Entomol.* 22, 268(1929).—A com. product contg.

30% *p*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub>, 40% *o*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> and 30% trichlorobenzene has been handled by the trade as an insecticide under the name *o*-dichlorobenzene. Pure *o*-C<sub>6</sub>H<sub>4</sub>Cl<sub>2</sub> is at present available only in small quantity at a high price.

C. H. RICHARDSON

**Toxicity of lead salts to insects.** FLOYD J. BRINLEY. Univ. Penn. *J. Econ. Entomol.* 22, 221-5(1929).—When fed by mouth, PbCO<sub>3</sub>, PbSO<sub>4</sub>, PbCrO<sub>4</sub>, and PbO are toxic to fall webworms (*Hyphantria cunea*) in the following order: chromate>sulfate>carbonate>oxide. Toxicity increases with the increase in mol. wt. of the salt. The amt. of Pb in the body of eastern tent caterpillars (*Malacosoma americana*), at the time of death, exclusive of the digestive tract, is const. regardless of the amt. of PbO ingested.

C. H. RICHARDSON

**Some effects of manganese sulfate and manganese chloride on nitrification.** D. H. NELSON. Iowa State College. *J. Am. Soc. Agron.* 21, 547-59(1929).—Mn compds. in small concns. may stimulate the nitrification of dried blood or (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub> in soil. There is no regularity of relationship between the concn. of Mn and the stimulation in nitrification. The stimulation in nitrification noted in the presence of Mn salts may be due to the negative ion and not to the Mn. High concns. of Mn salts retard nitrification but do not stop the process. Lime is very effective in reducing the toxic effects of Mn on nitrification in soil.

E. F. SNYDER

**Mercury salts as soil insecticides.** HUGH GLASGOW. *J. Econ. Entomol.* 22, 335-40(1929).—HgCl<sub>2</sub> in aq. soln. and HgCl in aq. suspension or as a dust were effective in checking the cabbage maggot (*Hylemyia brassicae*), the carrot rust fly (*Psila rosae*), and the onion maggot (*Hylemyia antiqua*). HgCl is especially valuable for this work as it does not injure tender plants and is highly efficient. It also has considerable value in checking certain seedbed diseases. Of 5 other insecticides used only naphthalene approached HgCl in effectiveness.

C. H. RICHARDSON

**Potato seed treatment experiments on Long Island with special reference to the organic mercury instant dips.** E. E. CLAYTON. New York Agr. Expt. Sta., *Bull.* No. 564, 32 pp.(1929).—Org. Hg compds. for treatment of seed potatoes were found more effective than HgCl<sub>2</sub>. Org. mercury treatments were effective against seed piece decay and tended to increase the yield.

J. J. SKINNER

**Tolerance of different species and varieties of plants to naphthalene vapor.** ALBERT HARTZELL. Boyce Thompson Inst. *J. Econ. Entomol.* 22, 354-60(1929); *C. A.* 21, 792; 22, 1821, 4197.—150 species and varieties of plants were fumigated with C<sub>10</sub>H<sub>8</sub> (1.5 and 2 oz per 1000 cu. ft. greenhouse space). The dahlia was one of the most tolerant plants to C<sub>10</sub>H<sub>8</sub>. Single fumigations at 2 oz. per 1000 cu. ft. controlled red spider (*Tetranychus telarius*), a thrips (*Heliothrips femoralis*), the onion thrips (*Thrips tabaci*) and a slug (*Limax maximus*). The lower dosage required repeated fumigations at 4-5 day intervals for satisfactory control.

C. H. RICHARDSON

**Eutettix tenellus (Baker) as a factor in the production of nicotine for insecticidal purposes.** WALTER CARTER, Bur. of Entomol. and R. F. CRAWFORD, New Mex. Agr. Expt. Sta. *J. Econ. Entomol.* 22, 158-60(1929).—The beet leaf-hopper (*E. tenellus*) causes a peculiar disease of tobacco planted for the production of nicotine. A native New Mexican variety of tobacco, called locally "poncha," is immune to the disease.

C. H. RICHARDSON

**Bentonite as a dust carrier for nicotine.** L. R. STREETER. New York State Agr. Expt. Sta. *J. Econ. Entomol.* 22, 234-5(1929).—On account of its high adsorptive powers bentonite (a colloidal clay) should not be used as a carrier in nicotine dusts if volatility of nicotine is desired. No decompn. of nicotine in bentonite-nicotine dusts was observed. Nicotine can be recovered from bentonite by steam distn.

C. H. R.

**Further results with fish oil as an adhesive (for lead arsenate sprays).** H. L. DOZIER. Delaware Agr. Expt. Sta. *J. Econ. Entomol.* 22, 140-6(1929).—A continuation of work previously reported (*C. A.* 22, 2025). Excellent results are obtained with early PbHAsO<sub>4</sub> sprays contg. fish oil but the mixt. cannot be used safely for later sprays as it will increase the quantity of spray residue on the fruit.

C. H. RICHARDSON

**A correlation between oil sprays and chlorophyll content of foliage.** JOSEPH M. GINSBURG. N. J. Agr. Expt. Sta. *J. Econ. Entomol.* 22, 360-6(1929).—Two varieties of apple trees were sprayed with an emulsion of highly refined (white) lubricating oil during July and Aug. The viscosity of the oil was 200 Saybolt at 100° F., the oil concn. 2%. No injury to the foliage occurred and the leaves were a darker green and contained appreciably more chlorophyll than those of untreated trees.

C. H. RICHARDSON

**Some observations on Japanese beetle injury. II. Sprayed communities.** G. F. MACLEOD. State Coll., Penn. *J. Econ. Entomol.* 22, 320-2(1929).—PbHAsO<sub>4</sub> coated with Pb oleate was used in an extensive spraying demonstration to control the Japanese

beetle (*Popillia japonica*). Properly sprayed trees or shrubs received 80-90% protection from foliage injury. Sprayed plants well within the area protected by sprays suffered less injury than the same species of plant on the outer boundary of the sprayed area. A small and only temporary protection was afforded unsprayed plants which were surrounded by sprayed plants. When the normal host plants are protected by sprays, some other plants which are ordinarily immune or only occasionally attacked are injured. The Pb-coated  $\text{PbHAsO}_4$  repels rather than kills the insect. C. H. R.

**Variation in resistance of aphids to toxic sprays.** NEELY TURNER. Crop Protection Inst. *J. Econ. Entomol.* 22, 323-6(1929).—The results of expts. with com. nicotine sulfate soln. against 7 species of aphids show a variation in species resistance to this compd. It was applied as an aq. spray without spreader. C. H. RICHARDSON

**Sulfonated oxidation products of petroleum as insecticide activators.** M. T. INMAN, JR. Kay Labs., Inc., West Nyack, N. Y. *Ind. Eng. Chem.* 21, 542-3(1929).—By the addn. of chemically treated oxidation products of Pennsylvania gas oil to a soln. of nicotine sulfate, the efficiency of the poison was considerably increased. The activator principle, entomological technic, process, chem. and phys. properties of the product and future possibilities are discussed. E. F. SNYDER

**The action of sulfur as a fungicide and as an ascaricide.** II. WM. GOODWIN AND H. MARTIN. South-Eastern Agr. Coll. Wye, Kent, England. *Ann. Appl. Biol.* 16, 93-103(1929); cf. *C. A.* 23, 1712.—Previous expts. by chem. methods (*C. A.* 23, 1712) showed that the volatile agent produced when S is applied to a heated surface is gaseous S. This conclusion has been subjected to biol. tests upon the fungi, *Erysiphe graminis* and *Sphaerotheca humuli* and the gall mite, *Eriophyes ribis*. The fungi were not sufficiently sensitive to S to give concordant results; it is probable that actual contact of S particles with them is necessary to produce fungicidal action. The gall mite is affected by traces of S volatilized at ordinary temps. and filtration of the volatile agent through heated or cooled glass wool does not entirely remove it. These results on mites support the previous results from chem. tests. Relatively large concn. of  $\text{SO}_2$  and  $\text{H}_2\text{S}$  are without permanent effect on the gall mite and therefore are not responsible for the ascaricidal action of S. C. H. RICHARDSON

**The sulfur dioxide content of the air and its influence on the plant.** GUSTAV KÖCK, PAUL RECKENDORFER AND FERDINAND BERAN. Bundesanstalt f. Pflanzenschutz. *Fortschr. Landw.* 4, 170-2(1929).—Clover was exposed to concns. of  $\text{SO}_2$  from 1 part per 200,000 to 1 part per 20,000 for periods of 1 to 4 hrs. One such exposure did not affect the digestible protein content and only the higher concns. caused an increase in S content. LAWRENCE P. MILLER

**A laboratory method for determining the attractiveness of bands to codling moth larvae.** C. R. CUTRIGHT AND J. S. HOUSER. Ohio Agr. Expt. Sta. *J. Econ. Entomol.* 22, 62-4(1929).—Wooden posts are erected in pairs in the laboratory or outdoors. The base of each post is surrounded by a barrier to prevent the escape of the codling moth larvae (*Carpocapsa pomonella*). Two bands are compared on each pair of posts. Band A is placed 6 inches from the top of one post and band B, 6 inches below A. On the other post the location of the bands is reversed, band B being placed nearest the top of the post. Larvae are placed on top of each post and allowed to enter the band. The total number of larvae entering the A bands is then balanced against the total number entering the B bands. Results from wet and dry bands and bands treated with  $\beta$ -naphthol and untreated are given. C. H. RICHARDSON

**Observations on the oil-nicotine combination for the control of the codling moth and other apple insects in the Pacific Northwest.** F. B. HERBERT., Balfour, Guthrie and Co., San Francisco, Calif. AND M. D. LEONARD, Tobacco By-Products and Chem. Corp. Louisville, Ky. *J. Econ. Entomol.* 22, 72-8(1929).—Results of 2 yrs.' experimentation show that a spray consisting of a light, highly refined (white) petroleum oil and nicotine sulfate emulsified with casein gave, in most cases, economic control of the codling moth, *Carpocapsa pomonella*, and other more important apple insects. The use of this spray considerably simplified the arsenical spray residue problem on apples. C. H. R.

**Experiments with talc and other dusts used against recently hatched larvae of the oriental and codling moths.** BYRLEY F. DRIGGERS. New Jersey Agr. Expt. Sta., New Brunswick, N. J. *J. Econ. Entomol.* 22, 327-34(1929).—Coarsely and finely ground mica and finely ground talc applied to peach foliage in the lab. killed a high percentage of newly hatched larvae of the oriental fruit moth (*Laspeyresia molesta*) before they entered the twigs. Field tests showed the superiority of talc over mica or  $\text{Ca(OH)}_2$  in adherence to foliage and reduction of larval entry into the twigs. Talc and mica dusts were also effective in killing young codling moth larvae (*Carpocapsa pomonella*). The expts. are preliminary. C. H. RICHARDSON

**Manganese arsenate as a control for the codling moth.** RALPH L. MILLER. State Plant Board, Sanford, Fla. *J. Econ. Entomol.* 22, 340-5(1929).—In lab. expts., Mn arsenate, with or without lime, was not quite as effective as  $\text{PbHAsO}_4$  in preventing entrance of young codling moth larvae (*Carpocapsa pomonella*) into apples. When mixed with lime-sulfur soln. little difference in the toxicity of the two arsenates was noticed, although the toxicity of both was reduced. In field expts. Mn arsenate mixed with lime-sulfur soln. was as good or better than  $\text{PbHAsO}_4$ ; without lime-sulfur soln.  $\text{PbHAsO}_4$  was slightly better. Spray residues of Mn arsenate on fruit are more easily removed than are those of  $\text{PbHAsO}_4$ . C. H. RICHARDSON

**An operation in practical control of codling moth in a heavily infested district.** III. THOMAS J. HEADLEE. N. J. Agr. Expt. Sta. *J. Econ. Entomol.* 22, 89-97(1929); cf. C. A. 23, 467.—A review is given of a 3-year cooperative effort to control the codling moth (*Carpocapsa pomonella*) in heavily infested apple orchards. A progressive increase in quantity of clean fruit results from spraying with  $\text{PbHAsO}_4$ . A film of  $\text{PbHAsO}_4$  on fruit and foliage was more effective than a spotty coating. Eight to ten gals. of liquid spray contg.  $\text{PbHAsO}_4$  in the proportion of 4 lbs. in 100 gals. water is generally sufficient to give an optimum quantity of As deposit on a tree 25 ft. high and 30 ft. in diam. The addn. of casein spreaders and stickers (3 lbs. in 100 gals. water) to the arsenical spray appears to give the optimum coating. Method and time of application of  $\text{PbHAsO}_4$ , spray residues and orchard sanitation are also discussed. The application of proper amts. of miscible pine oil to the portions of the tree covered by rough bark destroyed all overwintering larvae without injuring the tree. C. H. RICHARDSON

**Preliminary report on attractants for peach insects.** OLIVER I. SNAPP AND H. S. SWINGLE. U. S. Bur. of Entomology. *J. Econ. Entomol.* 22, 98-101(1929).—Lab. and field tests showed that the plum curculio (*Conotrachelus nenuphar*) was slightly attracted by gallic acid, Me formate, benzaldehyde, phenylhydrazine, distillate of green peaches, phenylglycine and salicylaldehyde; the peach borer (*Aegeria exitiosa*) by benzyl butyrate, the lesser peach borer (*Aegeria pictipes*) by Et benzoate, mixt. of Ca malate plus acetaldehyde, Na bisulfite, phenol, salicylaldehyde, distillate of green peaches and peach bark distillate; the shot-hole borer (*Scolytus rugulosus*) by peach bark distillate and fermented aq. ext. of peach bark; the spotted cucumber beetle (*Diabrotica duodecimpunctata*) by oil of thyme and benzyl alc.; the soldier beetle (*Chauliognathus marginatus*) by phellandrene, anethole, benzyl alc. and oil of thyme; gnats (*Siphonella* sp.) are strongly attracted by isoamyl valerate and also attracted by thymol, carvacrol and Me heptenone; ants by phenylacetaldehyde and guaiacol; the wasp (*Vespa carolina*) by Et malonate. The results are considered to show little promise from the standpoint of control. Methods are described. C. H. RICHARDSON

**A study of baits, with special reference to the oriental fruit moth.** S. W. FROST. Penn. State College. *J. Econ. Entomol.* 22, 101-8(1929).—Baits contg. glucose, levulose, lactose, sucrose, invert sugar and a no. of com. sirups having various proportions of sucrose and glucose were used to attract the oriental fruit moth (*Laspeyresia molesta*). Some of the baits contained  $\text{Na}_2\text{AsO}_3$ . High-grade com. sirups were superior to com. centrifugal sirups and to the cheaper brands of refiners' sirups. Sucrose, glucose and levulose alone were not very attractive, but mixts. of them which contained certain inorg. compounds present in the molasses were very attractive. Conclusions: Sugar baits have not furnished a satisfactory method of reducing the oriental fruit moth population in an orchard. Molasses baits contg.  $\text{Na}_2\text{AsO}_3$  are superior to baits contg. molasses alone during hot weather because fermentation is restrained and the bait is effective over a long period.  $\text{Na}_2\text{AsO}_4$  was not found to be equal to  $\text{Na}_2\text{AsO}_3$ . A number of other insects including fruit flies and noctuid moths were attracted to the baits but not in numbers sufficient to reduce the population. C. H. RICHARDSON

**A digest of additional experiments in the application of *p*-dichlorobenzene in solution against the peach borer.** F. H. SIRGLER AND LUTHER BROWN. U. S. Bur. of Entomol. *J. Econ. Entomol.* 22, 217-21(1929).—This is a continuation of studies previously reported (C. A. 22, 1647). *p*- $\text{C}_6\text{H}_4\text{Cl}_2$  dissolved in gasoline is as effective as *p*- $\text{C}_6\text{H}_4\text{Cl}_2$  crystals against *Aegeria exitiosa* even if the soil about the peach tree is not prepd. before treatment and banked afterward. The use of 1 oz. *p*- $\text{C}_6\text{H}_4\text{Cl}_2$  in more than 50 cc. gasoline is attended by decreased efficiency. C. H. RICHARDSON

**Some factors that limit artificial control efforts for the oriental peach moth, *Laspeyresia molesta* Busck.** ALVAH PETERSON. Ohio State Univ. *J. Econ. Entomol.* 22, 108-15(1929).—The control of the oriental fruit (peach) moth is still an unsolved problem. No insecticidal control or orchard practice yet proposed is either satisfactory or practical. The more important factors that limit control by artificial means, including ovicides, larvicides, dormant control measures, light traps, attractants (baits) and

repellents, are discussed and opinions on the future possibilities of chemical control are given.

C. H. RICHARDSON

**Preliminary tests with possible repellents of the oriental peach moth.** J. WILLIAM LIPP. U. S. Bur. of Entomology. *J. Econ. Entomol.* 22, 116-26 (1929).—Sprays of crude  $\alpha$ -naphthylamine and Dippel's oil (lab. tests) and furfural, Dippel's oil,  $(\text{NH}_4)_2\text{S}$ , and amyl acetate (orchard tests) were repellent to the oriental fruit (peach) moth, *Laspeyresia molesta*. Methods are described. A useful contact insecticide may be made by dissolving *p*-dichlorobenzene in oleic acid and then treating the mixt. with an alkali to form a soap, which is miscible in water and from which the *p*-dichlorobenzene shows little tendency to crystallize as the temp. is lowered.

**Fertilizer.** EMIL BAUER and EISLER & SZOLD. Ger. 475,429, Feb. 23, 1927. See Austrian 108,903 (C. A. 22, 4709).

**Fertilizers.** PAUL M. MILLAND and ROBERT CAYN. Fr. 647,376, Jan. 14, 1928. A fertilizer is produced by roasting waste galalith below 100° for about 3 hrs. Fr. 647,377 describes a fertilizer obtained from waste from fleshing hides and tanneries while still moist and impregnated with  $\text{Na}_2\text{S}$  or similar products by mixing the flesh with  $\text{Fe}_2(\text{SO}_4)_3$ , drying and heating in a furnace to a max. of 100° and afterwards grinding.

**Fertilizers.** I. G. FARBENIND. A.-G. Fr. 650,287, Mar. 2, 1928. A fertilizer having improved storing and fertilizing properties over Chile salt-peter contains a max. of 60, and preferably 20-50%  $\text{NaNO}_3$  mixed with  $\text{KNO}_3$ .

**Vinasses.** GEORGES BRIOIS. Fr. 650,804, Mar. 13, 1928. Vinasses obtained from the distn. of molasses are concd. to about 38-40° Bé., a small amt. of  $\text{Na}_2\text{SiO}_4$  or  $\text{K}_2\text{SiO}_3$  is added, and the pasty mass obtained is dried at a low temp. and ground for easy transport as a fertilizer.

**Fumigant comprising hydrocyanic acid and chlorocarbonic ethyl ester or similar lachrymatory warning substance.** FERDINAND FLURY (to Deutsche Ges. für Schädlingbekämpfung m. b. H.). U. S. 1,712,917, May 14.

**Disinfecting seeds.** ERNST W. SCHMIDT (to the Firm I. D. Riedel-E. deHaen A.-G.). U. S. 1,711,545, May 7. Ca fluosilicate and Cu carbonate are used together.

**Weed killing.** OLIVER C. ROBERTS. Australia 10,015, Oct. 24, 1927. Prickly pear and other noxious plants are destroyed by projecting a mixt. of Na arsenate and sand or grit into the plant.

## 16—THE FERMENTATION INDUSTRIES

C. N. FREY

**Distillation and fractionation processes used in the alcohol industry.** D. B. KEYES. *Trans. Illinois Acad. Sci.* 21, 236-44(1928).—A review article discussing those processes which have been developed within the last few years and which are responsible for the large-scale production of certain valuable solvents. Flow sheets are shown.

L. L. QUILL.

**Alcohol in solid form.** HEINZ OHLE. *Apoth. Ztg.* 44, 467(1929).—A reply to a recent paper by Weiss (cf. *C. A.* 23, 2781) in which O. shows that while an alc. soln. contg. 2% gelacol yields a rather soft mass, firmer products may be obtained by dissolving more gelacol or using a stronger alc. Since all so-called solid alcs. lose alc. on exposure, they must naturally be packed and shipped in suitable air-tight metal containers.

W. O. E.

**The alcohol yield from rye and wheat.** STAIGER. *Brennerei-Ztg.* 46, 88(1929).—The av. alc. yield of 20 samples of rye was 34.40 cc. per 100 g. rye (31.20-36.0), showing most of the samples to be rich in starch. Most of the 12 samples of wheat were judged to be comparatively low in starch; the av. alc. yield was 34.00 cc. alc. per 100 g. wheat (31.20-37.50).

B. C. BRUNSTETTER

**The preparation of butyl alcohol and acetone by fermentation.** A. ULLRICH. *Metallbörse* 19, 5-6, 61-2, 229-30(1929).—A review.

W. C. EBAUGH

**The kinetics of acetaldehyde formation in alcoholic fermentation by dry yeast.** BRUNO KISCH AND JESAJA LEIBOWITZ. *Univ. Köln. Biochem. Z.* 207, 384-94(1929).—Under optimum conditions of the sulfite-sugar relation and concn. of both substances (2.5%  $\text{Na}_2\text{SO}_3$ , 1-3% sugar) aldehyde formation is practically a linear reaction. This linear course of the reaction is not affected by temp. although, of course, the velocity of the reaction increases with rising temp. until the enzyme begins to be inactivated by heat. The optimum temp. zone is between 31° and 38°. The induction time is also influenced by temp., a fact which must be considered in the study of fermentation.

S. MORGULIS

**The determination of formic acid in vinegar.** W. SCHUT. *Chem. Weekblad* 26, 228 9(1929).—Introduce 1 cc. of the substance in a fermentation tube and add very carefully concd.  $\text{H}_2\text{SO}_4$  until entirely filled; add 1 or 2 small stirrers of about 1 cm. length, made from pieces of iron wire in glass, and bring them to the top with a magnet and move them around rapidly. Put in oven at about 105°, stirring frequently. After 4 hrs. there is usually no more gas produced, and after cooling to room temp. every cc. reading gives 2 mg. formic acid, which can be reduced to 0° and 76 cm. Hg. If more than 3 cc. CO gas is produced, a smaller quantity must be taken for analysis.

J. C. JURRJENS

**Some very old wines.** G. ISSOGLIO. *Ann. accad. agr. Torino* 70, 47-51(1927).—The phys. characteristics and analyses, giving alc., total ext., reducing sugars, glycerol, tartaric, malic, succinic, acetic and tannic acids, ash, alky. of ash, total esters and volatile esters, are given in tables for Barolo (year 1836), black Sardinian (1825), Bordeaux (1836) and Lacrima di Cadice (1849) wines.

**Denaturing alcohol.** I. G. FARBENIND. A.-G. Brit. 298,611, Oct. 12, 1927. Denaturants are used comprising those fractions of coal-tar pyridines boiling above 120° and only slightly sol. in water, or sparingly sol. homologs of pyridines such as are obtained from croton aldehyde or acetylene or paraldehyde and  $\text{NH}_3$  with or without water-sol. pyridines.

**Denaturing alcohol.** I. G. FARBENIND A.-G. Brit. 298,617, Oct. 12, 1927. Denaturants are used comprising neutral substances which render the alc. distinctive in taste and odor even after fractionation over acid or alkali, filtration through charcoal or shaking with paraffin oil. Among the substances which may be used are: methyl thiocyanate, allyl alc., allyl carbinol, diethyl sulfide, dimethyl sulfide, methylethyl sulfide, diacetyl sulfide, acetonitrile, thioacetic ester, thiobutyric ester, ichthyol oil and products contg. these or similar substances in admixts. of which several examples are given.

**Treating alcoholic liquors.** THOMAS D. KELLY. Fr. 648,848, Aug. 22, 1927. EtOH, or material contg. it is mixed with up to 10% glycerol and treated with ultra-violet rays, a small proportion of Ca phosphate being added to check acidification. The product may be solidified by mixing with marine algae or farina, heating to 80° and cooling suddenly. It may be powd. and mixed with medicinal or food products as a stimulant or preservative.

**Glycerol.** ALLAN T. COCKING and CECIL H. LILLY. Ger. 472,870, Jan. 26, 1921. Glycerol, with AcH and alc., is prepd. by the yeast fermentation of sugar in the presence of sol. alkali bisulfite and normal alkali sulfite.

**Organic acids.** RICHARD FALCK. Ger. 473,727, Jan. 19, 1924. Org. acids are produced by the mycelia of fungi which are allowed to develop on a bed composed of a mixt. of nutritive material and materials which give off an acid gas. A suitable mixt. is agar soln. and  $\text{CaCO}_3$ . *Aspergillus* on this mixt. produces citronellic acid.

**Citric acid.** MONTAN- UND INDUSTRIALWERKE VORM. JOH. DAV. STARCK. Fr. 650,072, Feb. 17, 1928. Mold fungi such as *Aspergillus niger* used for the production of citric acid by the fermentation of carbohydrates is cultivated in alternating stages including cultivating in solid media such as gelatin and agar agar, cultivating in liquid media under the condition of industrial fermentation and cultivating on vegetable media such as fruit pulp contg. org. acids and vitamins. The wort used is such as would be used in alc. fermentation, part of the nutritive N being in the form of org. compds, particularly amino acids. Protective substances, which cloak the acidity of the citric acid, such as albumins or their degradation products, or non-fermentable carbohydrates of high mol. wt., may be added. Examples of the fermentation are given.

**Lactic acid.** I. G. FARBENIND. A.-G. (Martin Luther and Hans Beller, inventors) Ger. 472,914, Feb. 13, 1927. Lactic acid is prepd. from the lactate-contg. evapn. residues from the fermentation of carbohydrates, by extg. the lactate with MeOH and decomposing the ext. with acid, or esterifying it with acid and alc. Thus, 1 part of the evapn. residue of potato pulp neutralized with lime is extd. with 5 parts MeOH at 35-40°, until the lactate content of the ext. falls below 3%. The MeOH is removed by distn., the residue contg. about 92% Ca lactate. This can then be treated with acid or esterified.

**Molasses residues.** AKTIESELSKABET DANSK GAERINGS INDUSTRI. Fr. 649,424, Jan. 25, 1928. The residual liquors from the treatment of molasses for the production of yeasts, etc., are treated with microorganisms which will destroy betaine,  $\text{HCOOH}$ , humic substances and albumins. The decompn. of sulfates into  $\text{H}_2\text{SO}_4$  is avoided by the use of pure cultures under absolutely sterile conditions.

**Treating waste fibers.** HIPPOLYTE R. FOUQUE. Fr. 650,110, Aug. 9, 1927. Waste fibers from the agave and other plants are worked up for the *production of alc., fuel and fertilizers* by subjecting the waste to repeated pressing in presses of the continuous type, accompanied by intermediate disintegration and washing to obtain juice and pressed cake. The juice is afterward heated in a sterilizing app. of tinned Cu or Al, said app. being placed in a battery to effect the filling, heating, cooling and discharge in a continuous manner. The juice is fermented out of contact with air by means of

Moreau yeast obtained from the agave plant. The pressed cake is used as fuel and the ash therefrom as a fertilizer. Details of the app. are described.

**Brewing.** HANS KOCK and RUDOLF QUITT. Fr. 650,255, Mar. 1, 1928. A mash tub is described having a central tube surrounding a heating means, the liquid traveling up the tube and being distributed through branch tubes at the top. Cf. C. A. 23, 1466.

**Vinification of grapes.** EDMOND CHERREAU. Fr. 650,712, Mar. 10, 1928. An app. is described for the vinification of grapes. The whole grapes are heated to 80° by circulation of fresh juice suitably heated, whereby the cells of the grape skin are killed, and autolysis of the coloring matter and other substances in the skin is activated giving red wines without fermentation in the vat.

**Sterilization of wine.** SOC. ALFA-LAVAL. Fr. 651,061, Mar. 20, 1928. Wines are sterilized by adding finely divided neutral substances such as fuller's earth,  $\text{SiO}_2$ , etc., to which the microorganisms adhere, and sepg. the particles by centrifugal force.

**Wines, etc.** CHARLES O. BERTIN. Fr. 650,903, Mar. 16, 1928. Fermentation for the production of wines and other products is carried out by a succession of different ferments, each ferment being removed before the next is added. Thus, natural grape juice is fermented partly with an Algerian yeast, partly with a Sauterne yeast and partly with a Champagne yeast, each yeast imparting a particular flavor to the wine.

**Beverages.** PHILIPPE MALVEZIN. Fr. 648,825, June 27, 1927. Wines obtained by the fermentation of grape or other juice are dealcoholized by distn. under reduced pressure at a temp. of about 45–55°.

**Beverages; yeast.** MAURICE J. J. BOUTTEAUX. Fr. 649,741, July 20, 1927. In the manuf. of beer, the liquor expressed from the yeast after removal from the fermentation vats is used for the production of vinegar by the addn. of an acetic ferment; the yeast is purified by the elimination of dead cells and dried.

**Treating yeast.** ERNST PRIBRAM and HUGO WERTHEIM. Austrian 112,464, Oct. 15, 1928. Yeast is improved, particularly as regards durability, by treatment with  $\text{EtOH}$  of a concn. not exceeding 50% by vol., followed by washing with water. The treatment may be begun with  $\text{EtOH}$  of about 10% concn., the concn. gradually rising as the treatment proceeds. The treatment may be applied in a centrifuge or suction filter. Cf. C. A. 23, 1466.

**Yeast.** A. J. C. OLSEN and INTERNATIONAL YEAST CO., LTD. Brit. 299,336, June 21, 1927. In a continuous-addn., continuous-withdrawal process for producing yeast by propagation in 3 or more sep. quantities in successive stages of yeast growth, the yeast environment is controlled in at least the first 2 of the stages including continuous addn. of yeast nutrient materials, in such a manner as to maintain constancy of quality of the yeast produced as a final product. Three or more sep. yeast propagating tanks are connected in series; seed yeast added to them may be of the same or of different generations. Various addnl. details and modifications are described.

**Yeast.** NORDDEUTSCHE HEFEINDUSTRIE A.-G. Fr. 650,891, Mar. 16, 1928. A durable yeast is obtained by keeping yeast of any desired kind in motion during 6–12 hrs. in weak solns. of alc. (e. g., 0.25–1% by vol.), made poor in N and dried in a known manner. As alc. soln. the yeast wort itself or alc.-contg. wort from other fermentation processes may be used.

## 17—PHARMACEUTICAL CHEMISTRY

W. O. EMERY

**Essential oil of root of *Cyperus rotundus* L. of Japan.** I. Y. KIMURA AND M. OHTANI. *J. Pharm. Soc. (Japan)* 48, 971–7(1928).—By steam distn. K. and O. obtained about 1% essential oil. This contains some fatty acids. By fractional distn. under reduced pressure K. and O. obtained two chief fractions called, resp., cyperene (yield 32%),  $\text{C}_{15}\text{H}_{24}$  (I),  $b_7$  110–115°,  $d_{13}^{13}$  0.9372,  $[\alpha]_D^{13}$  1.5°, and cyperol (yield 49%),  $\text{C}_{15}\text{H}_{22}\text{O}$  (II)  $b_8$  147–150°,  $d_{20}^{20}$  1.0055,  $[\alpha]_D^{19}$  29.5°. Catalytic reduction of I with Pd and  $\text{BaSO}_4$  gave dihydrocyperene,  $\text{C}_{15}\text{H}_{26}$ ,  $b_{12}$  113–116°,  $d_{19}^{19}$  0.9332,  $[\alpha]_D^{19}$  7.6°. Catalytic reduction of II gave dihydrocyperol,  $\text{C}_{15}\text{H}_{26}\text{O}$ ,  $b_{10}$  145–148°. Chemical properties of I and II are given. F. I. NAKAMURA

**Review of pharmaceutical and pharmacological chemistry.** S. BERLINGOZZI. *Giorn. chim. ind. applicata* 10, 609–612(1928); cf. C. A. 23, 1717.—A review of drugs recently introduced, among them, the alkaloid, bulbocapnine, used in paralysis agitans, abnormal muscular sensibility, etc.; the anesthetic, diocaine,  $\text{EtOC}_6\text{H}_4\text{NHCMc}:\text{NC}_6\text{H}_4\text{OEt}$ , which is better than holocaine, and optocaine B, a mixt. of adrenaline, *p*-amino-

benzoate of diethylaminoethanol, and K and Mg salts; it is less toxic than novocaine; the arsenical derivs., as treparsol, 3,4-(HCONH)(HO)C<sub>6</sub>H<sub>4</sub>AsO(OH)<sub>2</sub>, which is given orally in syphilis. Sb and Bi salts such as CO(NH<sub>2</sub>)<sub>2</sub>·(C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>SbO)<sub>2</sub>·5H<sub>2</sub>O, urea, stibamine and bismuthyliodoxyquinolinic acid have also been used in this disease.

A. W. CONTIERI

**Microchemical reaction for physostigmine.** M. WAGENAAR. *Pharm. Weekblad* 66, 381-2(1929).—The reaction between physostigmine salts and Na salicylate, whereby characteristic crystals are formed, is capable of detecting 10 mg. of the alkaloid at a diln of 1:200. The formation of supersatd. solns. may be avoided by addn. of (NH<sub>4</sub>)<sub>2</sub>SO<sub>4</sub>. The reaction with AuCl<sub>3</sub> giving a brownish red ppt. is sensitive to 5 mg. of alkaloid at a diln. of 1:500. The first reaction has the advantage of being more specific. A. W. D.

**Microchemical reactions for piperine.** M. WAGENAAR. *Pharm. Weekblad* 66, 405-6(1929).—The alkaloid is too feeble a base to form characteristic salts or double salts. It crystallizes readily from 30% AcOH, and if the soln. is dil. it may be salted out by NaOAc. Another useful solvent is MeAc. The alkaloid or evapn. residue is treated with a small quantity of MeAc and the soln. dild. with H<sub>2</sub>O, whereupon characteristic crystals form. Quantities as small as 50 mg. may thus be identified. A. W. D.

**Sirup Fructus.** C. A. ROJAHN and GERTRAUT HAMANN. Univ. Halle-Wittenberg. *Apoth. Ztg.* 44, 467(1929).—A patented Swiss product "for asthmatic horses" proved on examn. to consist essentially of H<sub>2</sub>O, 5% EtOH, about 2% plant ext. (juniper) and 0.4% aq. As soln. W. O. E.

**Evaluation of sodium cacodylate.** D. A. B. 6. G. FRIEDLÄNDER. *Apoth. Ztg.* 44, 528-9(1929).—After a review of the official Ger. method, and also that of Schulek and Villecz, the following procedure is suggested as yielding satisfactory results. In a 100-cc. Kjeldahl flask introduce 0.1 g. (accurately weighed) of the sample and 3 cc. 30% H<sub>2</sub>O<sub>2</sub> soln. After some agitation carefully add 10 cc. concd. H<sub>2</sub>SO<sub>4</sub> and heat with a small flame until the effervescence ceases. Again add, drop by drop, 2 cc. 30% H<sub>2</sub>O<sub>2</sub>, and heat as before and finally with the full flame. After cooling add 50 cc. H<sub>2</sub>O, transfer quantitatively to a titration flask, add KMnO<sub>4</sub> soln. (1:100) to a persistent red and discharge with a crystal of C<sub>2</sub>H<sub>2</sub>O<sub>4</sub>. When fully cooled add 3 g. KI, and a half hr. later titrate the pptd. I with 0.1 N hypo (without indicator) to a colorless soln. Not less than 8.75 nor more than 9.35 cc. hypo should be required for every 0.1 g. of the sample, an amt corresponding to 32.8 to 35.0% As. W. O. E.

**Capillary analysis of homeopathic preparations.** H. NEUGEBAUER. *Pharm. Ztg.* 74, 626-7(1929); cf. C. A. 23, 2532.—An exptl. study of the luminescence effects obtained by ordinary and ultra-violet light on capillary pictures from aconite, tobacco, barberry, cherry laurel, oleander and arnica. W. O. E.

**Rapid method for the examination of ergot fluidextract.** K. HERING. *Apoth. Ztg.* 44, 542(1929).—In a small separatory funnel shake vigorously 1/2 min. a mixt of 1 g. fluidext. of ergot, 5 g. petr. ether and 5 g. distd. H<sub>2</sub>O. Withdraw the aq. layer to a 2nd separatory funnel, add 5 g. Et<sub>2</sub>O and shake vigorously 1/2 min., then with a pipet transfer the upper layer to a narrow test tube contg. 2 cc. H<sub>2</sub>SO<sub>4</sub>, add 1 drop FeCl<sub>3</sub> soln. (1:100). In the course of 10 to 30 mins. a blue-violet to cornflower-colored ring develops in the event of a full strength sample. W. O. E.

**Bromometric and rhodanometric estimation of essential oils. II.** H. P. KAUFMANN. Univ. Jena. *Arch. Pharm.* 267, 249-67(1929); cf. C. A. 23, 1467.—From a large no. of expts. it was found that the approved MeOH soln. of Br, when satd with NaBr, may be advantageously employed in the investigation of essential oils. In the examn. of substances like geraniol, linalool, citral, anethole, terpineol, thymol, cinnamaldehyde, vanillin, carvone, geranyl acetate and linalyl acetate values were obtained which may be regarded as true I nos. The transition points in the bromination process are clearly discernible and persist in most cases for considerable periods. Free rhodan behaves very like a mildly reacting pseudo-halogen. In cases where the theoretical rhodan no. (corresponding to the I no.) is obtained, longer reaction periods are required (anethole, citronellol, terpineol). More interesting are the cases in which a pronounced *partial action* (as compared with the Br behavior) is observable. In a series of cases (linalool, linalyl acetate, geraniol, geranyl acetate, citral, thymol) 1 mol. of rhodan reacts where 2 mols. of Br would be involved; the rhodan value is in such cases equal to 1/2 the I no. In certain instances, as with cinnamaldehyde, the rhodan technic was inoperative. In addn. to expts. with natural mixts. of essential oils, many results are reported on artificial mixts. W. O. E.

**Testing of drugs in recent times.** G. BÜMMING and K. FERREIN. *Arch. Pharm.* 267, 310-20(1929).—A review. W. O. E.

**Estimation of cineole in eucalyptus oil.** PHILIP A. BERRY. *Australasian J.*

**Pharm. 1929, 203-6.**—The results of the work here recorded show that the *o*-cresol method gives satisfactory values with the oil of *E. cneorifolia*, which is one of the comparatively few species of eucalyptus exploited commercially for the production of medicinal eucalyptus oil, whereas the  $H_2PO_4$  method has been shown to yield hopelessly inaccurate results. While the degree of accuracy of the *o*-cresol method itself is not high compared with analytical methods in general, it nevertheless yields concordant results, and is certainly much better than any method yet suggested for the estn. of cineole.

W. O. E.

**Synthetic drugs.** FRANCIS H. CARR. *Chemistry & Industry* 48, 421-3 (1929).—An address given before the Brit. Sci. Guild, London, descriptive of a few prominent synthetic drugs in order to show the way in which our knowledge of chemistry and of the chem. changes of the body is developing, and enabling the manufacturer to supply that which the physician requires.

W. O. E.

**Assay of insulin on rabbits and mice.** A. KROGH AND A. M. HEMMINGSEN. *Kgl. Danske Videnskab. Selskab., Biol. Medd.* 7, No. 6, 13 pp. (1928).—The 2 tests followed are given in considerable detail, the one adopted with some minor modifications from the method of Marks, which depends on the fact that the hypoglucemic action of insulin within certain limits is proportional to the dose when measured as the av. fall of the blood sugar over a period of 5 hrs. following the injections. The essential modification is the use of the av. of the 1st and final values of the blood sugar as the base line, instead of the initial value only, as used by Marks. For the estn. of blood sugar the method of Hagedorn and Norman-Jensen was followed. The mouse convulsion test was studied, and the results obtained are plotted. A series of comparisons was instituted between the 2 methods. A prepn. which had been compared with the international standard by means of the mouse test, and made to correspond to the international standard with a mean error of  $\pm 5\%$ , was compared also in 5 expts. on 2 to 4 rabbits each, and found to be 94, 95, 96, 96 and 99% of the international unit, with an av. of  $96 \pm 3.5\%$ .

W. O. E.

**Essential oil of a new species of anemone leaf Boronia rich in ocimene.** A. R. PENFOLD. *J. Proc. Roy Soc. N. S. Wales* 62, 263-72 (1929).—The oil of the new species *B. dentigeroides* differed from that of *B. anemonifolia* (values in parentheses) in yield of oil 1.3 to 2% (0.6 to 1%), ester no. 15-34 (54-128), pinene under 30% (75%), ocimene 75-80% (trace only). The principal constituents of the new oil are: ocimene, *d*- $\alpha$ -pinene, *d*-limonene (total terpenes 90%), darwinol and corresponding caprate, isovalerate, and acetate, Et formate (?) with small amts. of sesquiterpenes, phenolic substances and paraffin m. 64-6°.

W. O. E.

**Sicilian and Calabrian essences of the season 1928-1929.** G. H. OGSTON & MOORE. *Perfumery and Essent. Oil Record* 20, 111-2 (1929).—With lemon oil the unusually high optical rotation of the past season was continued during the present. The % of citral is appreciably lower, very few samples exceeding 5%; the *d*. is generally low. Numerous typical results obtained have been tabulated. For sweet orange oil the rotation was rather high, very few being lower than 98.5°. The *d*. was between the usual limits 0.8475-0.849, while the non-volatile residue rarely exceeded 1.80%. The bergamot oil of the present season is very like that of the past.

W. O. E.

**Boronia oils—essential oil from a boronia in the pinnate section.** A. R. PENFOLD. *Perfumery and Essent. Oil Record* 20, 113-6 (1929).—A summary of the essential oils from 4 species of *Boronia*, namely *pinnata*, Müllerii, thujona and thujona var. "A," show comparative values in the order named: yield 0.02-0.1, 0.38-0.57, 0.5-0.8, 0.5-0.6%;  $d_{15}^{20}$  0.8784-0.8917, 1.0197-1.0265, 0.9121-0.9152, 1.056;  $n_D^{20}$  1.4762-1.4825, 1.5125-1.5150, 1.4526-1.4543, 1.5255-1.5260; constituents limonene, *d*- $\alpha$ -pinene, sesquiterpene, paraffin; elemicin (70-90%), *d*- $\alpha$ -pinene, geraniol, geranyl acetate;  $\alpha$ - and  $\beta$ -thujone (80-90%), sesquiterpene, paraffin, safrole (75-80%), limonene, sesquiterpene, phenols, paraffin. The oils from all 4 species were strongly fluorescent, probably because of the presence of Me anthranilate.

W. O. E.

**General characterization of perfumes and aromatics.** FRED WINTER. *Pharm. Monatsh.* 10, 36-9, 74-6 (1929).—An address given before the Austrian Pharm Assn. dealing with natural and synthetic perfumes and perfume materials.

W. O. E.

**Preparation and testing of pepsin wine.** W. BRANDRUP. *Apoth. Ztg.* 44, 578-9 (1929); cf. *C. A.* 23, 667.—A study has been made of the  $p_H$  of various pepsin wines, that prepd. with fruit wine having the acidity of 1.4, with sherry 1.8, with malaga 1.8 and with the official D.A.B. 6 prepn. 1.8. The acidity optimum for digestion of 2.2 to 2.5 is accordingly not reached.

W. O. E.

**Drugs and drug adulteration during the year 1927.** C. HAHMANN. *Apoth. Ztg.* 44, 561-3, 589-92(1929); cf. *C. A.* 22, 3259.—A review of adulterations observed in the Inst. für angew. Botanik. W. O. E.

**Determination of optical activity in the D. A. B. 6.** G. WALLRABE. Univ. Königsberg i/Pr. *Pharm. Ztg.* 74, 646-7(1929).—A discussion of the Ger. Pharm. requirements. W. O. E.

**Cacao butter.** BODINUS. *Pharm. Ztg.* 74, 647-8(1929).—A commentary on the standards of the D. A. B. 6. W. O. E.

**Detection of minute quantities of apomorphine in morphine solutions.** FRITZ WISCHO. Univ. Graz. *Pharm. Monatsh.* 10, 66-7(1929).—The behavior of certain *o*-hydroxy compds. toward vanadium-sulfuric acid reagent is described. The limits of sensitiveness to color formation are shown; that for apomorphine is 1:100000. In the presence of morphine the only difference in behavior observed is the transitory nature of the color produced by the reagent. Nearly all com. samples of morphine, notably after being heated in aq. soln., gave a positive test for apomorphine. W. O. E.

**Ultra-violet capillary analysis of pharmaceutical drugs.** PAUL ERNST AND EDEL TRUDIS JENTSCHITSCH. *Pharm. Monatsh.* 10, 67-73(1929).—Results are recorded of the examn. of some 134 different samples of crude drugs (capillary analysis of their aq. exts. in filtered ultra-violet light). W. O. E.

**Scientific pharmacy.** RAPP. *Pharm. Ztg.* 74, 464-8(1929).—The production and general technic of ampuls are discussed. W. O. E.

**Conservation of anesthetic chloroform.** I. G. OBERHARD. *Pharm. Ztg.* 74, 516(1929).—A commentary on recent papers by the author and by K. Bodendorf (cf. *C. A.* 23, 2531) on the same subject. W. O. E.

**Alkaloids of cusparia bark.** J. TRÜGER. *Pharm. Zentralhalle* 70, 213-22, 229-34, 245-52(1929).—A review of our present knowledge of the subject. W. O. E.

**Examination of alkali iodides.** WALTER MEYER. *Pharm. Ztg.* 74, 628(1929).—Alkali iodides which correspond fully to the Pharm. requirements may after some time decompose with deposition of I. Such products contain thiosulfates in such amts as to escape detection by application of the usual official method. A delicate test to det the presence or absence of such contamination consists in adding to a freshly prepd. soln of the sample (1 to 19 parts previously boiled and cooled H<sub>2</sub>O) several drops of starch soln and dil. H<sub>2</sub>SO<sub>4</sub>, whereupon a blue color should not immediately develop; on further addn. of 1 drop of a mixt. of 1 cc. 0.1 *N* I soln. and 9 cc. H<sub>2</sub>O to 10 cc. of the above iodide soln. a pure blue color should immediately appear, which persists on agitation. W. O. E.

**Fluidextract of condurango and its testing.** II. JESCHENBRENNER. *Pharm. Ztg.* 74, 628-9(1929).—An exptl. study more particularly with respect to the requirements of the Ger. Pharm. W. O. E.

**Development of pharmacy from the 16th to the 18th century.** LUDWIG WINKLER. *Pharm. Ztg.* 74, 607-8(1929).—An address. W. O. E.

**Production of isosafrole.** R. PRIESTER. Tech. Hochschule Delft. *Riechstoffind.* 4, 41-2(1929).—After reviewing some recent more or less successful attempts to convert safrole into isosafrole, P. shows how the conversion may be effected almost quantitatively by heating 200 g. charges of safrole with 1 g. KOH at about 9 mm. Hg pressure and in a specially constructed refluxing app. providing side-condensation of the distillate and its withdrawal whenever desired for detg. the  $n_D^{20}$ . The process may be made continuous. W. O. E.

**Composition of the essential oil of Nepeta cataria var. citriodora Beck.** B. N. RUTOVSKII AND I. V. VINOGRADOVA. Chem.-Pharm. Forschungsinst. Moskau. *Riechstoffind.* 4, 43(1929).—Previous work on this oil is reviewed in connection with the examn. of a number of different samples. W. O. E.

**Norwegian juniper oil. II. Terpenes and other constituents of the oil.** AXEL JERMSTAD. Univ. Oslo. *Riechstoffind.* 4, 44-5(1929).—Norwegian juniper contains *l*- $\alpha$ -pinene, camphene, sabinene, terpinene and 4-terpinenol. W. O. E.

**Microchemical distinctions of ethereal oils.** L. ROSENTHALER. *Am. J. Pharm.* 101, 191-6(1929).—See *C. A.* 21, 1870. W. G. GAESSLER

**$\beta$ -Anthraquinonemonosulfonic acid as a microchemical reagent for alkaloids.** L. ROSENTHALER. *Am. J. Pharm.* 101, 196-7(1929).—R. found that this reagent is a general alkaloidal precipitant, although some of the ppts. are not wholly insol. In many cases they are amorphous. Those in which crystals appear are described resulting from the addn. of the cryst. alkaloidal base or salt to a 10% soln. of the reagent. W. G. G.

**Some recent research achievements in pharmacy.** JOHN C. KRANTZ. *Am. J. Pharm.* 101, 269-75(1929).—A review. W. G. GAESSLER

**Comments on the alcohol tests in the German Pharmacopeia.** HENRY LEFFMANN. *Am. J. Pharm.* 101, 275-7(1929).—The test for MeOH depends upon the formation of HCHO by the action of acid permanganate in the cold, but the details of the procedure are such that unless much greater accuracy and delicacy are obtained than with the usual procedure there is no reason for adopting it. The detailed procedure is outlined. There seems to be nothing in the line of convenience, delicacy or certainty to recommend the method over that given in the U. S. P. X. which continued experience shows to be delicate, trustworthy and convenient. The test for acetone is the well-known reaction with NaOH and Na nitroprusside. It is sufficient and fairly characteristic, but indicates also aldehyde if present in notable amt. W. G. GAESSLER

**The Norwegian cod-liver oil industry.** JOSEPH W. ENGLAND. *Am. J. Pharm.* 101, 282-9(1929).—Methods of obtaining the oil are described. Measures taken to produce an oil of high quality and to store it in such a manner as to prevent deterioration are discussed in particular. It is not yet established that irradiated ergosterol is the therapeutic equiv. of cod-liver oil in all respects. W. G. GAESSLER

**Neodorm, a new soporific of the aliphatic series. I. Its chemistry and toxicology.** W. BIEHLER, G. HILDEBRANDT AND E. LEUBE. *Deut. med. Wochschr.* 55, 56-7(1929).—Neodorm, a com. prepn. of  $\alpha$ -bromo- $\alpha$ -isopropyl butyramide, was found to be a valuable and safe hypnotic. II. Its pharmacology. H. FREUND. *Ibid* 57. III. Clinical experiences. PAUL KACZANDER. *Ibid* 57-8. ARTHUR GROLLMAN

**The chemistry, pharmacology and clinical use of acedicon. I. Chemical studies.** CL. SCHÖPF. *Deut. med. Wochschr.* 55, 302-3(1929).—Acedicon is prepd. by reduction of thebaine and the substitution of  $2\text{CH}_3\text{CO}$  groups for  $2\text{CH}_3\text{O}$  groups. It is a cryst. compd., m. 154-6°, insol. in  $\text{H}_2\text{O}$  and easily sol. in org. solvents. It is not decompd. by boiling its aq. soln. for 1 hr., but is hydrolyzed by mineral acids to form AcOH and dihydrocodeine. II. Pharmacological studies. HERMANN WIELAND and BEHREND BEHRENS. *Ibid* 303-5. III. Clinical experience with acedicon. W. NONNENBRUCH and E. RISCHAWY. *Ibid* 305-6. ARTHUR GROLLMAN

**The manufacture and properties of organic antimony compounds.** E. R. KANN. *Metallhorse* 18, 1797-9(1928).—Because of their therapeutic properties, org. Sb compds. are today prepd. in large quantities; these compds. are particularly effective in the treatment of tropical diseases. In many cases the Sb preps. are much more effective than As preps. Methods of manuf. are described for alkyl and aryl stibines and their oxides and salts, mixed As-Sb compds. of the arseno type, stibonic acids and stibonium compds. B. HAMILTON

**Preservation of pharmaceuticals.** FRANT. RYBÁŘ. *Časopis Českoslov. Lékárnictva* 8, 193-6(1928).—R. confirms the value of methyl *p*-hydroxybenzoate as a preservative in pharmaceutical preps. such as sirups, mucilages, etc., as suggested by Sabalitschka (*C. A.* 21, 2157). WILLIAM J. HUSA

**Behavior of colloidal silver preparations in aqueous solution.** OLDŘICH TOMÍČEK. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 196-202(1928).—"Solv-argent" contains 7.8% ionic Ag and "Argol" contains 1.3%; both preps. have a protective colloid contg. S in org. combination. "Thiargol" contains 20% Ag, of which 0.5% is ionic; in aq. soln. (2-0.03%),  $p_{Ag} = 8.0-6.5$ . In solns. of the same concn. "Ichthargan" (30% Ag) shows  $p_{Ag} = 1.8-2.2$ . In aq. solns. (2-0.06%), "Choleval" and "Targesin" give  $p_{Ag} = 4-3.5$ . WILLIAM J. HUSA

**The determination of silver by different methods in some colloidal silver preparations.** E. BUREŠ AND T. RUBEŠ. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 202-7(1928).—The object of the work was to find a rapid and accurate method for detn. of Ag in colloidal Ag preps. The best results were obtained with a method based on oxidation of the org. matter with concd.  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , followed by titration with  $\text{NH}_4\text{CNS}$ . WILLIAM J. HUSA

**Cyclamine.** E. BUREŠ AND J. BERGAUER. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 208-11(1928).—The tubers of *Cyclamen europeum* were extd. with 88-90% alc., boiling twice in succession. In this way was isolated crude cyclamine, contg. impurities such as coloring matter and resinous material; the yield was 11.4%. After further purification, cyclamine was obtained in cryst. form, m. 253-4°. Cyclamine appears to have very strong hemolytic properties. WILLIAM J. HUSA

**Comparative analyses of American and Philippine cigarettes.** V. G. LAVA AND S. B. FORTMA. Philippine Agr. Expt. Sta. Los Baños. *Philippine Agr.* 17, 565-77(1929).—Philippine-made cigarettes contain less  $\text{C}_2\text{H}_4$ ,  $\text{Et}_2\text{O}$  and  $\text{EtOH}$  exts. and more  $\text{H}_2\text{O}$  ext., ash, total N and protein than most American cigarettes. If the sum of the  $\text{C}_2\text{H}_4$ ,  $\text{Et}_2\text{O}$  and  $\text{EtOH}$  exts. be represented by A and the  $\text{H}_2\text{O}$  ext. by B, the ratio A/B will not

be less than 2.0 with cigarets of good quality. Eight references are appended.

A. L. MEHRING  
The determination of sparteine in broom tops (*Sarothamnus scoparius* Koch). P. BOURGET. *Bull. sci. pharmacol.* 36, 235-7(1929).—Heat 10 g. of cut tops to 100° for 1 hr. with 100 cc. of a 2% soln. of trichloroacetic acid. Filter through cotton and repeat the extrn. until a sample is no longer pptd. by the reagent of Valser. Add to the cold and united exts. 5 cc.  $H_2SO_4$  and a satd. soln. of  $KMnO_4$  until a permanent pink color appears. Destroy the excess of  $KMnO_4$  with some drops of  $NaHSO_3$  and ppt. with a 5% soln. of silicotungstic acid in slight excess. Filter and wash with 2%  $H_2SO_4$ , dry and calcine in conformity with the method given by Javillier (*C. A.* 5, 1906). The ppt has the compn.  $SiO_2 \cdot 12WO_3 \cdot 2H_2O \cdot 2C_{11}H_{25}N_2$  and after calcination a residue,  $SiO_2 \cdot 12WO_3$ , is left.

A. E. MEYER  
The phytotoxins, MICHEL MACHEBOEUF. *Bull. sci. pharmacol.* 36, 237-52 (1929).—A monograph about phytotoxins, their definition and principal properties, prepn., physiologic action on animals, biologic action *in vitro* and immunization. The following substances are discussed: ricin, abrin, crotin, robin and phallin.

A. E. MEYER  
Study of commercial lecithins and specialties with lecithin base. II. JACQUES SONOL. *Rev. facultad cienc. quim.* (Univ. La Plata) 5, 83-104(1929); cf. *C. A.* 23, 2533.—Pharmaceutical prepn. contain 3-10% lecithin emulsified in physiol. salt soln. of 0.7-0.93%  $NaCl$ . The phys. and chem. qualities of commercial products are detd. As decompn. occurs, injectable prepn. are not stable for more than 6 months. The therapeutic value was reported favorable in six cases.

A. E. MEYER  
Some physical studies of iodized preparations used in pharmacy. E. CANALS AND P. SUIFFET. *J. pharm. chim.* 8, 308-13(1928); cf. *C. A.* 22, 1611.—No certain conclusions can be drawn as to the colloidal nature of I in 9 products examd. except perhaps in reference to iodized  $H_2O$ , and a mixt. of tincture of I and  $H_2O$ , which partly contain non-ultrafiltrable I. With iodized tannin, dialysis, ultra-filtration and especially the degree of ionization of the product show that there is no colloidal I in the prepn.; it is present entirely in the cryst. state.

S. WALDBOTT  
Stability of sirup of ferrous iodide. H. E. BECKER AND F. F. BERG. E. R. Squibb & Sons. *J. Am. Pharm. Assoc.* 18, 503-4(1929).—The cause of the darkening of this product in storage is still unknown. A specimen was prepd. by using boiled distd.  $H_2O$ . It was subdivided into flint bottles which were completely filled. Part were evacuated and N was admitted; part were stored in varying temps., including the icebox. In 3 months all specimens at room temp. showed darkening while the icebox specimens were not discolored although sucrose had crystd. In 9 months the cold specimens showed slight discoloration. I had not been set free. Two other sets were prepd., one strictly U. S. P. and another in which citric acid was substituted for the hypophosphorous acid. All were stored in flint bottles in cardboard containers (to restrict light) at ordinary temp. After 4 months the U. S. P. product had changed in color while the others had not.

**Medicine from animal chyle.** TORII & Co., LTD., and H. MORI. Brit. 299,530, Aug. 2, 1927. A remedy for use by injection is obtained by purification of chyle of animals which have been fed on fat. Details of the purification are given.

**Antiseptic compositions.** V. LEONARD. Brit. 299,522, July 29, 1927. A compn. suitable for use as an antiseptic on tissue surfaces, dental or surgical instruments or false teeth, etc., comprises hexylresorcinol dissolved in glycerol and dild. with water to obtain a clear soln. of low surface tension.

**Anesthetic mixture of ethylene and ether.** MERLE B. CHENEY (to Cheney Chemical Co.). U. S. 1,712,250, May 7.  $C_2H_4$  together with a smaller proportion of ether vapor (suitably about 0.5–5.0% the quantity of the  $C_2H_4$ ) is subjected to a pressure of at least 1000 lbs. per sq. in. in order to produce a free-flowing non-freezing product.

**Theobromine.** NAAMLOOZE VENNOOTSCHAP SOCIETEIT VOOR CHEMISCHE INDUSTRIE "KATWIJK." Fr. 651,490, Mar. 19, 1928. See Brit. 287,507 (C. A. 23, 483).

**Arsphenamine.** KAORU MATSUMIYA and HISAKAZU NAKATA. U. S. 1,713,475, May 14. A cathode soln. for the prepn. of arsphenamine by elec. reduction comprises a soln. of HCl of over 4.7 N and 3-nitro-4-hydroxyphenylarsinic acid.

**Iodine compounds.** WM. M. SINCLAIR. Australia 11,512, Feb. 1, 1928. Iodized glucoprotein substances having *therapeutic properties* are prepd. by macerating cacti in boiling water, neutralizing in the presence of S, maintaining the temp. until the evolution of gas ceases, fermenting, adding I and reboiling until the I is taken up.

**Purifying calcium cresolsulfonates.** I. G. FARBERIND. A.-G. (Siegfried Jaeger, inventor). Ger. 475,270, July 9, 1922. Aq. solns. of the Ca salts of acids obtained by the direct sulfonation of cresols are freed from cresol, cresylate and other volatile impurities by steam distn. The products are intended for the treatment of respiratory diseases.

**Mineral waters.** SOC. FRANÇAISE DU "ROYAL VICHY." Fr. 651,117, Mar. 22, 1928. Medicinal mineral waters such as "Vichy" are made agreeable to the taste by emulsifying them in an atm. of  $CO_2$  with sirups, alcoholates, oils of citron, orange, mint, cinnamon, etc.

**Disinfectant.** FLUXO PRODUCTS CO., INC. Ger. 475,305, July 8, 1925.  $NaHSO_4$  is mixed with 2–10% of vegetable ivory. A small amt. of a blue water-sol. dye may be added also.

**Tooth paste.** DONALD H. SEYMOUR and ADOLF FRIEDBERG. Can. 288,933, April 23, 1929. A tooth paste comprises invert sugar 1500 g., distd. water 500 g., oil of peppermint 25 g., oil of cloves 25 g., pptd. chalk 200 g., and suitable coloring matter as carmine, coumarin or various aniline dyes.

**Dentifrice.** E. R. SQUIBB & SONS. Ger. 475,114, Nov. 13, 1924. A dentifrice paste comprises water-free  $Mg(OH)_2$  and glycerol, preferably with other addns. such as  $CaCO_3$ , antiseptics, and thickeners. The paste may be prepd. by adding glycerol to an aq. suspension of  $Mg(OH)_2$  and evapg. under reduced pressure until the water is removed.

## 18—ACIDS, ALKALIES, SALTS AND SUNDRIES

E. M. SYMMES

**New operating method for the manufacture of nitric acid by the ammonia oxidation process.** I. M. LINBSON. *J. Chem. Ind. (Moscow)* 6, 8–12(1929).—The purpose is to improve the  $HNO_3$  yields and to reduce the reaction space, which in existing methods requires too cumbersome a plant app. The principal factor influencing the velocity of transformation of NO to  $HNO_3$  and also the concn. of the acid finally obtained is the concn. of NO in air. However, as the concn. of  $NH_3$  in air must not be above 10%, because of the need of a sufficient amt. of air for oxidation, it has been proposed to enrich the air by O. Even in this case the concn. of  $NH_3$  must not be above 13–14% for fear of formation of explosive mixts. To increase the partial pressure of NO it has also been proposed to operate under pressure. This presents no technical difficulty,

if the  $\text{NH}_3$  is also oxidized under pressure (*C. A.* 23, 242). The objection of Malyarevskii and Papkov (*C. A.* 22, 4727) that pressure affects adversely the reaction  $4\text{NH}_3 + 5\text{O}_2 = 4\text{NO} + 6\text{H}_2\text{O}$  is unfounded. The real objection to the use of pressure is that it acts unfavorably on the reaction  $3\text{HNO}_2 \rightleftharpoons \text{HNO}_3 + 2\text{NO} + \text{H}_2\text{O}$ , so that the  $\text{HNO}_3$  is obtained with a high  $\text{HNO}_2$  content. When the pressure is lowered after the operation, the  $\text{HNO}_2$  decomposes only partly into  $\text{NO}$  and  $\text{HNO}_3$ , and a special app. is required to absorb the  $\text{NO}$  thus emitted. Finally, as pressure decreases the speed of  $\text{NO}$  formation from  $\text{HNO}_2$ , the whole process is slowed down, since most of the time required in this process is used up by the oxidation of regenerated  $\text{NO}$ , and not by that of the original quantity of  $\text{NO}$ . The proposed method is based on the fact that most of the reaction space is needed to obtain the last 25-30%  $\text{HNO}_3$ , when the  $\text{NO}$  concn. in the gases becomes low. To obtain the first 70-75% of  $\text{HNO}_3$ , only 35-40% of the total reaction space is required, on condition that all  $\text{NO}$  is transformed into  $\text{HNO}_3$  at a yield of 93-4%. L. proposes to absorb 70-75% of the original amt. of  $\text{NO}$  in  $\text{HNO}_3$ -sprayed towers in the usual manner, after which the remaining gases are absorbed and transformed into  $\text{N}_2\text{O}_3$  in Gay Lussac towers sprayed with concd.  $\text{H}_2\text{SO}_4$ . Only about 5% of the gases entering the Gay Lussac towers would escape absorption. After ejecting the gases by means of a pump (if they are not to be used as a N source)  $\text{N}_2\text{O}_3$  is introduced into a special small, acid-proof distn. column placed at the inlet.  $\text{N}_2\text{O}_3$  enters it from the top, while a current of hot  $\text{NO}$  from the  $\text{NH}_3$  contact oxidation app. enters from the bottom. The temp. of the latter gases reaches  $550^\circ$ , as they enter the column directly after the contact reaction and are not passed through a steam boiler as usual. Due to the high temp. and the current of inert gases ( $\text{NO}$ , not having had time to oxidize to  $\text{N}_2\text{O}_3$ , acts as an inert gas),  $\text{N}_2\text{O}_3$  decomposes and the  $\text{NO}$  formed is released into circulation. Because of the high temp. (about  $260^\circ$ ) of the gases, the  $\text{H}_2\text{O}$  vapors which they contain are not absorbed by  $\text{H}_2\text{SO}_4$ , which has a temp. of  $130-140^\circ$ , and do not dilute the latter. The gases being thus enriched in the denitration column to a 13.5%  $\text{NO}$  content enter the recuperating column. In the latter, which is sprayed from the top by 50%  $\text{HNO}_3$ , the N gases cool to  $150-60^\circ$ , after which they are passed through a cooling tower sprayed with 20-25%  $\text{HNO}_3$  and finally enter the absorption towers at  $40-45^\circ$ . The usual gas coolers should not be employed, as they require considerable surface. The absorption towers are  $\frac{3}{4}$  filled with small pieces of quartz. A fine spray of  $\text{HNO}_3$  enters the unfilled quarter of the absorption towers, and the  $\text{NO}$  gas current, which enters from the bottom, is thus oxidized. The total yield of  $\text{HNO}_3$  by this process should reach 98%, and the total required reaction space is reduced to 25-30 square meters per ton of  $\text{NH}_3$  burned. Calcs. and reaction equations are given.

BERNARD NELSON

**Sulzer compressors for the production of synthetic ammonia.** A. ELSNER *Z. ges. Kälte-Ind.* 36, 1-8(1929).—The pressures used in the various com. methods for producing synthetic  $\text{NH}_3$  are discussed. Two compressors, a six-stage, 2000 cu. m. per hr., 300 atm., and a four-stage, 7600 cu. m. per hr., 27 atm. are described. F. D. R.

**Oxidation of ammonia from crude by-product liquors.** G. A. PERLEY AND W. P. WHITE. Univ. of New Hampshire. *Ind. Eng. Chem.* 21, 564-7(1929).—The use of a crude  $\text{NH}_3$  liquor high in S as a source of  $\text{NH}_3$ -air mixt. for oxidation temporarily inactivated a Pt gauze catalyst. Removal of the S was accomplished by washing with an aq. suspension of  $\text{NiS}$ , which acts catalytically in the oxidation of  $\text{NH}_4\text{HS}$  to free S.

T. H. CHILTON

**Manufacture of aluminum chloride from clays.** I. E. ADADUROV. Kharkov State Inst. Appl. Chem. *J. Chem. Ind. (Moscow)* 5, 1288-92(1928).—Seven samples of Don basin clays contg. 45.6 to 52.3%  $\text{SiO}_2$ , 33.07 to 39.5%  $\text{Al}_2\text{O}_3$ , a little of other oxides and moisture, were studied with a view of their utilization for direct conversion to  $\text{AlCl}_3$ . The first operation is the removal of  $\text{H}_2\text{O}$ , by burning to  $600^\circ$ . This affects the soly. of  $\text{Al}_2\text{O}_3$  in acids. When kaolin is heated to  $600^\circ$  its soly. in  $\text{HCl}$  increases at the rate at which it loses  $\text{H}_2\text{O}$ ; in the interval between 600 and  $800^\circ$  the soly. remains const.; at  $900^\circ$  it becomes perceptibly lower; and above  $1000^\circ$  the product becomes almost insol. The clays which are most sol. in  $\text{HCl}$  or  $\text{H}_2\text{SO}_4$  are those which have been heated between  $600^\circ$  and  $800^\circ$ . Within the temp. interval  $500-800^\circ$  kaolinite does not decompose into free  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$ , but forms a new silicate which is sol. in acids; hence the sol. constituents of calcined clays are not the free  $\text{SiO}_2$  and  $\text{Al}_2\text{O}_3$ , but kaolinite. Hence the importance of detg. the kaolinite contents of clay samples. The method is as follows: A known wt. of non-calcined clay is boiled 1 hr. in a beaker contg. 10 cc. of 20%  $\text{HCl}$  per g. of clay. One-half of the undecompd. residue is again boiled with 20%  $\text{HCl}$  for 1 hr., while the other half is first heated to  $600-800^\circ$  and then boiled 1 hr. with 20%  $\text{HCl}$ ;  $\text{Al}_2\text{O}_3$  is detd. separately in the 2 liquids and  $\text{SiO}_2$  is detd.

by treating the 2 undissolved residues with 50 cc. of a soln. 5%  $\text{Na}_2\text{CO}_3$  and 0.5%  $\text{NaOH}$  and with 25 cc. of a soln. of  $\text{KOH}$  per 1 g. of residue. The difference between the  $\text{Al}_2\text{O}_3$  quantities contained in the 2 filtrates is the  $\text{Al}_2\text{O}_3$  content of the kaolinite; on multiplying it by 2.533 the kaolinite content of the clay is found, the quantities of  $\text{SiO}_2$  found serving as a check. For the transformation of clays into  $\text{AlCl}_3$  it is best to use an agent contg.  $\text{Cl}$  in active form. Budnikov (*C. A.* 18, 2058) has shown that  $\text{COCl}_2$  is more effective than  $\text{Cl}$ , particularly at  $1000^\circ$  in the presence of  $\text{C}$ . A. believes that the superiority of  $\text{COCl}_2$  over  $\text{Cl}$  is due to the circumstance that the former dissociates at  $800^\circ$ , yielding nascent  $\text{Cl}$  which is more effective than ordinary  $\text{Cl}$ . The exptl. fact that the yield of  $\text{AlCl}_3$ , which is 98% at  $1000^\circ$ , drops to 56.3% at  $800^\circ$  when operating with  $\text{COCl}_2$  during the same length of time, is explained by the circumstance that at  $800^\circ$  the dissocn. of  $\text{COCl}_2$  is just beginning and, consequently, there is much less active  $\text{Cl}$  present than at  $1000^\circ$ . Budnikov's equation  $\text{Al}_2\text{O}_3 + 3\text{COCl}_2 = 2\text{AlCl}_3 + 3\text{CO}_2$  should be regarded as a reversible reaction, since at about  $1000^\circ$  some of the  $\text{AlCl}_3$  formed is converted back to  $\text{Al}_2\text{O}_3$  under the influence of the  $\text{CO}_2$  present. This explains the role of  $\text{C}$ , which Budnikov considered as a catalyzer, but which in reality takes part in the reaction by reducing  $\text{CO}_2$  to  $\text{CO}$ . The best effect is obtained when charcoal and clay are not only intimately mixed with each other, but cemented with mazouts or crude oil into porous briquets which absorb  $\text{Cl}$ . A real catalyzer in the reaction is  $\text{KCl}$  in the quantity of 5–10%; in its presence the reaction is accelerated, the yield is improved, and the operating temp. may be lowered to  $720\text{--}750^\circ$ .  $\text{FeCl}_2$  formed in the course of chlorination of clay can easily be sepd. from  $\text{AlCl}_3$ , as it is volatile at  $400\text{--}450^\circ$ . The latter circumstance may be utilized for obtaining  $\text{Al}_2(\text{SO}_4)_3$  free from  $\text{Fe}$  either by starting with chlorinated clays or by chlorinating  $\text{Al}_2(\text{SO}_4)_3$ .

BERNARD NELSON

**Studies on aluminum silicates. II. The dehydration vapor pressure of kaolin.** C. J. VAN NIEUWENBURG and H. A. J. Pieters. *The Tech. Univ. Delft. Rec. trav. chim.* 48, 406–16(1929); cf. *C. A.* 23, 2676.—Within certain limits of  $\text{H}_2\text{O}$  content of kaolin, the equation  $\log p_{\text{H}_2\text{O}} = -\frac{39,300}{4.57} \cdot \frac{1}{T} + 13.5$  is a rough approximation of

the equil. pressure. In reality the behavior of kaolin is not governed by laws of univariant equil. The loss of  $\text{H}_2\text{O}$  from kaolin was studied by a dynamic method at 17 mm., 140 mm., 1 atm. and 3.6 atm., and by the static method. As the pressure is increased the curves are more continuous than at the low pressures where the break in the curve is quite abrupt. The results of the static and dynamic method do not agree except in the form of the curve. A sample of pholerite, with a particle size of  $10\text{--}20\mu$ , was examd. at 1 atm.  $\text{H}_2\text{O}$  pressure and the decompn. temp. found to be  $60^\circ$  higher than with the kaolin sample with particle size of  $1\mu$ . A sample of kaolin dehydrated and rehydrated a no. of times showed a dehydration curve which was continuous, showing that hysteresis is present in the above results. The dissocn. pressure of kaolin is a function of  $\text{H}_2\text{O}$  content over the whole range.

ARTHUR FLEISCHER

**The manufacture of minium of alumina.** VICTOR CHARRIN. *Science & ind.* 13, 166 8(1929).—For some time "minium" designated only  $\text{Pb}_3\text{O}_4$ , but it is now used for a no. of substitutes, which are not only cheaper but also less toxic and less dangerous to use than the  $\text{Pb}$  compd. Bauxite, or rather the residue from treatment of this rock with  $\text{H}_2\text{SO}_4$  for removing  $\text{Al}_2(\text{SO}_4)_3$ , is used as the basis for the prepn. of minium of alumina. Red bauxite, contg. the most  $\text{Fe}$  oxide, is the most suitable source.

Manufacture of bleaching earths from clays. V. V. ZHADIN, E. P. ULYASHCHENKO AND V. I. ASTAFIEV. *J. Chem. Ind.* (Moscow) 5, 864-5(1928).—When natural clays do not possess a high degree of bleaching power they are usually subjected to mech. treatment or to activation by chem. reagents. These treatments are expensive and do not permit utilization of all the valuable constituents of clays. The authors propose a method which meets these objections. Assuming that aq.  $\text{SiO}_2$  is the decolorizing constituent of clays, the latter are heated with dil. 59-60° Bé.  $\text{H}_2\text{SO}_4$  at 120°, washed with hot  $\text{H}_2\text{O}$  till neutral, the residue is dried, pulverized and sieved. With a clay contg.  $\text{H}_2\text{O} + \text{CO}_2$  9.04,  $\text{Al}_2\text{O}_3$  22.65,  $\text{SiO}_2$  63.80,  $\text{Fe}_2\text{O}_3$  2.02,  $\text{CaO}$  0.58,  $\text{MgO}$  0.06,  $\text{K}_2\text{O}$  1.85 they obtained by this process a bleaching earth contg.  $\text{SiO}_2 \cdot n\text{H}_2\text{O}$  92.185,  $\text{Fe}_2\text{O}_3$  0.074,  $\text{Al}_2\text{O}_3$  5.17,  $\text{CaO}$  0.119,  $\text{MgO}$  trace,  $\text{K}_2\text{O}$  trace. The bleaching power of this earth was as high, and sometimes higher, than that of floridin. The wash waters obtained in the manuf. were concd. by evapn. to 23° Bé., freed in a centrifugal from Fe admixts., and the mass pressed out on the centrifugal was redissolved in hot  $\text{H}_2\text{O}$ ; on cooling, K alum was obtained. The mother liquors were evapd. to 45° Bé. and the white  $\text{Al}_2(\text{SO}_4)_3$  soln. obtained was, on cooling, cut into pieces; the latter contained  $\text{Al}_2\text{O}_3$  14,  $\text{Fe}_2\text{O}_3$  0.289, and a trace of free acid and insol. residue. Altogether 1 ton of clay gave 1 ton bleaching earth, 1 ton  $\text{Al}_2(\text{SO}_4)_3$  and 0.1 ton K alum. Any clay will give  $\text{Al}_2(\text{SO}_4)_3$  and bleaching earth by this process, but only clays contg. over 1% K give K alum. BERNARD NELSON

Manufacture of blanc fixe. I. E. ADADUROV. Kharkov State Inst. Appl. Chem. *J. Chem. Ind.* (Moscow) 5, 1420-4(1928).—To det. the conditions of obtaining the best  $\text{BaSO}_4$  ppt. various concns. of  $\text{BaCl}_2$  solns. were added to various concns. of equiv. amts. of  $\text{H}_2\text{SO}_4$ , after which the pptd. crystals were examined microscopically. The best concns. were found to be 20 g.  $\text{BaCl}_2 \cdot 2\text{H}_2\text{O}$  per 100 g.  $\text{H}_2\text{O}$ , and 20%  $\text{H}_2\text{SO}_4$ . The most favorable temp. is 60-70°. Both solns. must be stirred vigorously. The solns. must be in equiv. quantities. The presence of HCl up to 5% decreases the yield of  $\text{BaSO}_4$  2-2.5%, but further increases of HCl have no further influence on the yield. Filtration of the ppt. must be *in vacuo*. The crystals must be filtered off as soon as formed, for although they may be left under water for 48 hrs. without change, the mother liquors which contain an excess of  $\text{H}_2\text{SO}_4$  tend constantly to increase their size. The ppt. should be dried *in vacuo* at a temp. not exceeding 75-80°. BERNARD NELSON

Extraction of bromine from natural bromine waters. V. P. IL'INSKII AND V. M. FILIPPEO. *J. Chem. Ind.* (Moscow) 5, 833-8(1928).—The manuf. of Br in U. S. S. R. is carried out by steaming Saki (Crimea) lake water in a column with a current of Cl which liberates Br. Theoretically 0.44 tons of Cl are required to liberate 1 ton Br, but in practice almost twice as much Cl is used up on account of side reactions. The latter are due to the alky. of the lake water, as a result of which Cl produces chlorides, hypochlorites and chlorates. As the expense in Cl is very considerable, neutralization of the lake water with  $\text{H}_2\text{SO}_4$  before the Cl treatment is recommended. B. N.

Methods of selenium manufacture. A. GARNAK. *J. Chem. Ind.* (Moscow) 5, 1424-6(1928).—All existing methods of Se prepn. from the slimy deposits of  $\text{H}_2\text{SO}_4$  chambers were investigated and 3 new methods added. The sulfite method gives in the cold poor yields (47%) and has the drawback of requiring prolonged washing of the deposit to neutrality. On warming, the yield is improved to 60-70%, but the Se thus obtained is contaminated by up to 5% S. The bisulfite method gives yields below 20%. The oxidation method by  $\text{HNO}_3$  requires a lengthy operation and a considerable expense of the acid and yields but 64% Se. The oxidation method by  $\text{KClO}_3$  gives good results, but is objectionable on account of occurrence of explosions and also on account of the formation of a considerable amt. of  $\text{H}_2\text{SeO}_4$ , which has to be reduced to  $\text{H}_2\text{SeO}_3$  by boiling with HCl. To obviate the danger of explosion and obtain less  $\text{H}_2\text{SeO}_4$  this method was modified as follows: 600 g. of 40%  $\text{H}_2\text{SO}_4$  are added to 1 kg. of the

slimy deposit containing 3.2% Se, the mixt. is carefully stirred at 80–85° while a soln. of 150 g.  $\text{KClO}_3$  in 1 l.  $\text{H}_2\text{O}$ , previously warmed to 60–70°, is introduced in small portions during 4 hrs. The soln. is then filtered by suction through a wool cloth and the ppt. is washed twice by hot  $\text{H}_2\text{O}$ , 100 cc. being used each time, and dried at 50°. The yield is 26.3–26.4 g. Se, viz., better than 82%. Practically all the  $\text{H}_2\text{SeO}_4$  was reduced by  $\text{HCl}$  formed from the chlorate in the presence of bisulfite. The method of consecutive treatment by  $\text{H}_2\text{SO}_4$  and  $\text{HNO}_3$ , which is due to G., gives the highest Se yields. One kg. of the deposit contg. 3.4–3.6% Se is heated to 90° and with careful stirring 600 g. concd.  $\text{H}_2\text{SO}_4$  added in a thin stream, whereupon the temp. rises to 100°. After addn. of all the  $\text{H}_2\text{SO}_4$ , the heating is discontinued, and when the temp. reaches 70–80° 200 g.  $\text{HNO}_3$  (sp. gr. 1.4) are introduced gradually in small portions and with careful stirring. Each new portion of  $\text{HNO}_3$  is added only after the cessation of N oxides emission. After adding the last portion of  $\text{HNO}_3$ , the temp. is raised to 100° and the stirring is continued for 3 hrs.  $\text{H}_2\text{SeO}_3$  is then extd. with hot  $\text{H}_2\text{O}$  3 times, 1 l. being taken each time, and by decantation, after which the soln. is filtered *in vacuo*, all the solns. are united and after cooling treated with 140 g. com. bisulfite (thiosulfate). The mixt. is heated to boiling, the coagulated Se washed twice with  $\text{H}_2\text{O}$ , 100 cc. being taken each time, and dried at 50°. The yield is 92–3%. The method of oxidation by  $\text{Na}_2\text{Cr}_2\text{O}_7$ , also due to G., consists in heating to 95–100° 1 kg. of deposit containing 3.4% Se, adding with careful stirring first 600 g. concd.  $\text{H}_2\text{SO}_4$  and then a satd. soln. of 260 g.  $\text{Na}_2\text{Cr}_2\text{O}_7$ . The whole reaction requires 4 hrs., after which  $\text{H}_2\text{SeO}_3$  is extd. and treated as in the preceding method. The yield is 27.1 g., viz., 80%. G.'s best method from the points of view of yield and cost is oxidation by  $\text{MnO}_2$ . 600 g. concd.  $\text{H}_2\text{SO}_4$  are added with energetic stirring to 1 kg. deposit contg. 3.5% Se and 140 g.  $\text{MnO}_2$  is introduced gradually into this mixt. at 90–95°. The reaction ends within 2.5–3 hrs., after which  $\text{H}_2\text{SeO}_3$  is extd. with 3 l.  $\text{H}_2\text{O}$ . Ten g. tech.  $\text{HCl}$  and 120 g. thiosulfite are added to the united solns. and Se is coagulated by boiling, washed with 200 cc. hot  $\text{H}_2\text{O}$  and dried at 50°. The yield, 31.5 g., is 90% of the theoretical.

**Litharge-glycerol cement.** HANS STÄGER. *Z. angew. Chem.* 42, 370–9 (1929).—In judging the suitability or ease of reaction of a litharge, sedimentation tests of particle size are useless. The ease of reaction of the surface of the particles is more important. The quotient of wt./sedimentation vol. is even better. The oil no. gives the particle surface. Cement formation is dependent upon the  $\text{H}_2\text{O}$  content of the glycerol, which should contain about 15%  $\text{H}_2\text{O}$ . Unlike  $\text{ZnO}$  and  $\text{MgO}$  cements, which develop max. hardness at definite ratios of oxides and salt solns., the hardness of litharge-glycerol cement is rather dependent upon factors other than formation of chem. compds. First  $\text{PbO}$  hydrates, then optically active glyceride, which agglomerates to aggregates. A good cement should have a max. hardness in 20 hrs.

A compd. of  $\text{NH}_3$  with formic acid, such as formamide is rapidly heated under reduced pressure to 400-900° in the presence of a dehydrating catalyst such as thoria on pumice in such a manner that the vapors and gases are not heated substantially longer than is necessary for obtaining the desired temp. Cf. *C. A.* 22, 3023.

**Nitric acid.** AMMONIAQUE SYNTHÉTIQUE ET DÉRIVÉS (SOC. ANON.). Fr. 651,093, Mar. 21, 1928. Conc'd.  $\text{HNO}_3$  is obtained by oxidizing  $\text{NH}_3$  under pressure, only part of the water of reaction being allowed to react with the oxides of N, the excess being eliminated immediately after the condensation. The oxides of N are absorbed by bubbling the gas through the dil. acid formed during the reaction, and the dil. acid contg. the oxides is transformed into conc'd. acid by oxidation with O under pressure. The residual gases are heated by the gases coming from the oxidation chamber and they are expanded to recover a part of the energy.

**Phosphoric acid.** WLADIMIR KYBER. Ger. 475,128, Feb. 26, 1925. Addn to 449,585. According to Ger. 449,585, crude phosphates, coal and silicates are heated together in a shaft furnace and the gases evolved are treated with air in the amt. required to oxidize their content of P. This method is now modified by using  $\text{CO}_2$  instead of air, the treatment being effected at 1300° in a recuperator or Cowper stove.

**Liquid carbon dioxide.** WALDEMAR HESSLING. Swiss 129,689, Dec. 15, 1927.  $\text{CO}_2$  is liquefied by expansion after prior cooling by an agent which imparts a lower temp than 0°, such as  $\text{NH}_3$ .

**Solid carbon dioxide.** W. HESSLING. Brit. 298,910, Oct. 15, 1927. See Swiss 129,688 (*C. A.* 23, 2790).

**Sulfur trioxide.** ROBERT TERN. Fr. 650,684, Mar. 9, 1928. An app. is described for oxidizing S,  $\text{H}_2\text{SO}_4$  or  $\text{SO}_2$  and air to  $\text{SO}_3$  by the action of a high-tension current, oxides of N being formed at the same time which act as catalysts.

**Sulfur oxides by combustion of sulfur.** JOHN C. BOERTLEIN (to Grasselli Chemical Co.). U. S. 1,713,416, May 14. S and a combustion-supporting gas such as air are introduced into a closed chamber in which combustion is effected under conditions adapted to produce an increased pressure within the chamber which serves to develop power as in a Diesel engine.

**Nitrogen oxides from ammoniacal liquor.** DAVID L. JACOBSON (to The Koppers Co.). U. S. 1,713,045, May 14. Air is blown through ammoniacal liquor to produce a gas contg. N, O and  $\text{NH}_3$ , any  $\text{H}_2\text{S}$  present is oxidized (suitably by use of  $\text{Al}_2\text{O}_3$  as a catalyst) and the gas is then passed over a suitable catalyst such as one contg. Pt to effect reaction of the N and O with each other. An app. is described.

**Synthetic ammonia.** I. G. FARBENIND. A.-G. Fr. 650,721, Mar. 10, 1928. The mixt. of H and N is freed from harmful constituents such as S, P, As or their compds.

or CO by directing it onto metallic complex compds. heated to temps. below the temp. of the catalyst. In an example a double ferrocyanide of K and Al is used heated to 250° under 200 atm. pressure. Cf. C. A. 23, 1726.

**Synthetic ammonia.** NITROGEN ENGINEERING CORP. Fr. 650,728, Mar. 10, 1928. A mixt. of H and N is circulated in a cycle through a single catalytic converter, part of the  $\text{NH}_3$  formed is removed at one point before, and part at a 2nd point beyond, the pump and inlet for the fresh gases, this portion taking with it impurities from these gases and from the lubricating oil in the pump. Cf. C. A. 23, 2537.

**Dispersing insoluble salts.** AUGUST CHWALA. Fr. 650,177, Feb. 28, 1928. Dispersions in water of alk. earth metal and heavy metal salts of phosphoric and arsenic acids are obtained by using as peptizators the alkali metal salts of phosphoric and arsenic acids which have been obtained from ortho acids by loss of water or which may be considered as having been obtained in this manner. In examples Ca arsenate is ground with water and K Na metahexaphosphate or Na pyrothioarsenate, Ca phosphate with Na pyrophosphate, and Pb arsenate with Na pyrothioarsenate; in each case a colloidal suspension is obtained.

**Alkali hydrates.** LEO P. CURTIN. Fr. 651,128, Mar. 22, 1928. Alkali hydrates are prepd. by adding alkali sulfide to an agitated suspension of PbO in water, the addn. being regulated so as to avoid an accumulation of sulfide ions in the soln. The PbS is reconverted to PbO by treatment with  $\text{Na}_2\text{SO}_4$  followed by oxidation of the metallic Pb obtained.

**Alkali metal iodates.** I. G. FARBERIND. A.-G. Brit. 299,445, Oct. 28, 1927. See Ger. 468,213 (C. A. 23, 2254).

**Alumina.** METALLBANK UND METALLURGISCHE GESELLSCHAFT A.-G. Fr. 650,193, Feb. 29, 1928.  $\text{Al}_2\text{O}_3$  is obtained by heating CaO or  $\text{CaCO}_3$  with  $\text{Al}_2\text{S}_3$  and removing the CaS by washing with dil. acids.

**Aluminum oxide from sulfide.** FREIHERR CONWAY VON GIRSEWALD. U. S. 1,713,411, May 14.  $\text{Al}_2\text{S}_3$  is heated with CaO to a temp. (suitably about 800–900°) at least sufficiently high to cause exothermic reaction and the CaS is subsequently removed from the reaction product by leaching.

**Ammonium salts.** AMMONIAQUE SYNTHÉTIQUE ET DÉRIVÉS (SOC. ANON.). Fr. 651,094, Mar. 21, 1928.  $\text{NH}_4$  salts are prepd. by spraying acid into a chamber contg. gaseous  $\text{NH}_3$ . The vapor formed during the reaction is eliminated by condensation in a rectifying column at the side of the reaction chamber. The amt. of acid entering is controlled by a valve regulated by the pressure existing in the reaction chamber.

**Ammonium phosphate.** COMPAGNIE DES MINES DE VICOIGNE, NOEUX ET DROCOURT. Fr. 650,109, Aug. 9, 1927.  $\text{Ca}_3(\text{PO}_4)_2$  is put in suspension in water contg. an  $\text{NH}_4$  salt, and  $\text{CO}_2$  or  $\text{SO}_2$  and  $\text{NH}_3$  in convenient amts. are introduced at a temp. above 30°. A closed container is used for the process.

**Arsenious oxide.** FRANKLIN G. HILLS (to American Smelting and Refining Co.). U. S. 1,713,127, May 14. Material such as crude ore contg. As in oxidized form is mixed with coal, coke or other suitable reducing material which supports combustion, the material is placed in a shallow layer on a support pervious to air and the combustible material is ignited and air is blown through the mixt. to heat it without substantial disturbance of the mixt., to form and volatilize  $\text{As}_2\text{O}_3$  substantially free from dust.

**Bleaching barium sulfide or similar sulfide solutions by addition of sodium cyanide.**

EDWARD A. TAYLOR (to Grasselli Chemical Co.). U. S. 1,713,409, May 14.

**Hydrated oxides of chromium.** I. G. FARBERIND. A.-G. Fr. 650,572, Mar. 8, 1928. Green hydrated oxides of Cr are prepd. by heating chromic acid or its salts with reducing agents, except  $\text{SO}_2$ , at pressures below 150 atm. and in the presence of water. Examples are given in which  $\text{HCOONa}$ , flowers of S and H are used as reducing agents.

**Lead carbonate.** RENÉ DALOZE. Ger. 475,475, July 3, 1926. See U. S. 1,691,841 (C. A. 23, 488).

**Lead carbonate.** ALEXANDER NATHANSOHN, OTAVI MINEN- UND EISENBAHN GES., ARON HIRSCH, METALL- UND FABRIKWERKE A.-G., ZINKHÜTTE HAMBURG AND COMPAGNIE MÉTALLURGIQUE FRANCO-BELGE. Ger. 475,284, Sept. 24, 1924. Pb is recovered as  $\text{PbCO}_3$  from ores, metallurgical products, scrap, etc., by a process comprising essentially (1) extn. of the initial material which a chloride lye, e. g., with 53%  $\text{CaCl}_2$  soln., (2) pptn. of an oxychloride of Pb from the soln. by addn. of alkalies, and (3) sepn. of the oxychloride and treatment thereof with  $\text{CO}_2$ . Detailed examples are given.

**Potassium salts.** JEAN H. BRÉGEAT. Fr. 650,474, Mar. 5, 1928. KCl and  $\text{SiO}_2$ , e. g., sand, are fused together to form  $\text{K}_2\text{SiO}_3$ , which is dissolved in water and satd.

with  $\text{CO}_2$  to obtain  $\text{K}_2\text{CO}_3$  which may be converted into  $\text{K}_2\text{SO}_4$  and mixed with N and P fertilizers.

**Concentrating brines.** WILLIAM E. BURKE and HARALD DE ROPP (to American Potash & Chemical Corp.). U. S. 1,712,787, May 14. Brines such as Seales Lake, Calif. brine contg. carbonates, sulfates and chlorides of Na and K, and which are substantially satd. with NaCl and contain less  $\text{Na}_2\text{CO}_3$  than the quantity necessary to sat. the brine, are evapd. to a concn. less than that at which formation of glaserite begins, and the temp. is increased as the concn. is continued.

**Sodium and potassium fluorides.** ERICH ECKOLDT. Ger. 475,029, Aug. 7, 1926. A known method for the manuf. of KF consists in fusing  $\text{CaF}_2$  with  $\text{SiO}_2$  and KOH or  $\text{K}_2\text{CO}_3$ , whereby, on extn. with water, a soln. contg. KF and  $\text{K}_2\text{SiO}_3$  is obtained. This method is now improved by treating the soln. with HF,  $\text{H}_2\text{SiF}_6$  or  $\text{K}_2\text{SiF}_6$ , in order to convert the  $\text{K}_2\text{SiO}_3$  into KF and  $\text{SiO}_2$ . The soln. may then be treated with  $\text{Na}_2\text{CO}_3$  to obtain NaF, together with  $\text{K}_2\text{CO}_3$  for use again.

**Nickel and cobalt carbonyls.** I. G. FARBERIND. A.-G. Fr. 650,839, Mar. 14, 1928. See Brit. 296,558 (C. A. 23, 2538).

**Zirconium oxide.** Soc. MINIERE ET INDUSTRIELLE FRANCO-BRÉSILIENNE. Fr. 650,937, Aug. 19, 1927. Zircones ( $\text{SiO}_2 \cdot \text{ZrO}_2$ ) are mixed with  $\text{CaO}$ ,  $\text{CaCO}_3$ ,  $\text{CaSO}_4$  or  $\text{Ca}(\text{OC}_2\text{H}_5)_2$  and heated in an elec. furnace. The product is suspended in water and treated with HCl, the  $\text{ZrO}_2 \cdot \text{CaO}$  remaining unattacked. This is treated with concd  $\text{H}_2\text{SO}_4$  which seps.  $\text{CaSO}_4$ , and  $\text{ZrO}_2$  is recovered from the sulfate in the known manner.

**Trisodium phosphate hydrate.** LEON R. WESTBROOK. U. S. 1,711,707, May 7. A crystd. non-caking decahydrate is prepd. by heating an aq. satd.  $\text{Na}_3\text{PO}_4 \cdot 10\text{H}_2\text{O}$  soln. above its crystn. temp., seeding with decahydrate crystals and removing the decahydrate crystals formed.

**Carbon disulfide.** I. G. FARBERIND. A.-G. Fr. 648,889, Dec. 16, 1927.  $\text{CS}_2$  is obtained by treating hydrocarbons, particularly gaseous hydrocarbons such as  $\text{CH}_4$ , with gases such as  $\text{H}_2\text{S}$  capable of liberating S at a high temp. with or without catalysts. Thus,  $\text{CH}_4$  and  $\text{H}_2\text{S}$  in the proportion of 1:2 are passed through porcelain tube heated to  $1000^\circ$  and contg. fragments of baked clay; the issuing gases are intensely cooled to sep.  $\text{CS}_2$ . Cf. C. A. 23, 2791.

**Salt-graining apparatus.** THORVALD C. COLBIORSEN. U. S. 1,712,651, May 14. Structural features.

**Hydrogen.** FRANK C. BLAKE (to Lazote, Inc.). U. S. 1,713,325, May 14.  $\text{CH}_4$  and steam are caused to react in the presence of a catalyst such as a Ni-ceria-alumina catalyst of a temp. of  $400\text{--}700^\circ$  with a vol. ratio of steam to  $\text{CH}_4$  within the range between 3.5:1 and 44:1 and at substantially a "minimum value" for the temp. used (curves for this being given) and for a predetd.  $\text{CH}_4$  conversion and CO content of the resulting gases. Cf. C. A. 23, 3058.

**Hydrogen from carbon monoxide by use of catalysts.** M. CASALE-SACCHI. Brit. 299,492, July 25, 1927. Reaction of water in liquid state with CO or gases contg. CO is effected (suitably at temps. of  $180\text{--}360^\circ$  and under 20–150 atm. pressure) in the presence of catalysts such as reduced Cu, Ni, Fe,  $\text{Ti}$ , Pt or Pd or metallic oxides or metallic salts of weak inorg. acids or their mixts. The reaction may be effected in a tower contg. water in which is the catalyst (the gas being passed through in small bubbles). Exit gases pass through a heat exchange device to heat incoming gases and thence to a  $\text{CO}_2$  eliminator. The reaction may be regulated to obtain a H-CO mixt. for MeOH synthesis or a H-N mixt. for  $\text{NH}_3$  synthesis. Cf. C. A. 22, 3497.

**Phosphorus and cement.** I. G. FARBERIND. A.-G. Fr. 650,412, Mar. 5, 1928. See Brit. 287,036 (C. A. 23, 489).

**Silica.** I. G. FARBERIND. A.-G. Fr. 651,151, Mar. 23, 1928.  $\text{SiO}_2$  as a sol. gel or solid mass is prepd. from silicates along with compds. of Si which are easily hydrolyzed. In an example, cooled sol. glass of sp. gr. 1.070 is stirred, and cooled  $\text{SiCl}_4$  is run in. A limpid sol is formed which, after a little, becomes a homogeneous gel contg. about 100 g. of  $\text{SiO}_2$  per l. It is washed with distd. water and dried. Cf. C. A. 22, 1446.

**Silica in light bulky form.** P. SPENCE & SONS, LTD., T. J. I. CRAIG and A. KIRKHAM. Brit. 299,483, April 28, 1927.  $\text{SiO}_2$  which when dry weighs about 1 g. per 10 cc. is obtained by pptn. from a soln. of alkali silicate in the presence of alkali monocarbonate or bicarbonate soln. (suitably at a temp. of about  $70\text{--}95^\circ$  and with such a quantity of the carbonate that the soln. after the pptn. contains more than 2 mols. of monocarbonate from every 3 mols. of  $\text{SiO}_2$  originally present); the liquid is cooled and filtered and the  $\text{SiO}_2$  washed with water and, if necessary, further washed with acid and then again with water and dried and sieved.

**Silica sols.** I. G. FARBERIND. A.-G. Fr. 650,634, Mar. 9, 1928.  $\text{SiO}_2$  sols of

high percentage are made by treating, after elimination of sol. constituents, silicic gelatins in the known manner with a small quantity of  $\text{NH}_3$  and submitting them without further addn. of water to a raised temp. while avoiding vaporization of water until soln. is produced.

**Silica gel.** I. G. FARBENIND. A.-G. Fr. 650,800, Mar. 13, 1928. Molded  $\text{SiO}_2$  gel is prepd. by molding and drying a sol contg. at least 60, but preferably 90–160, g. of  $\text{SiO}_2$  per l. A gel having narrow pores is obtained from a slightly acid, neutral or feebly alk. sol which has during the contraction a  $p_H$  value less than 6 and preferably between 2 and 4. Gels having large pores are obtained from a sol having a  $p_H$  value above 7, and preferably between 7.2 and 9. Cf. C. A. 22, 144.

**Gels.** THE SILICA GEL CORP. Fr. 650,695, Mar. 9, 1928. Hard, tough gels of  $\text{SiO}_2$ , tungstic acid,  $\text{Al}_2\text{O}_3$ ,  $\text{TiO}_2$  or mixts. thereof having a d. not above 0.5 after heating to  $871^\circ$  are prepd. by heating the hydrogel slowly to  $79$ – $163^\circ$  under conditions which prevent dehydration, and slowly cooling it. The hydrogel may be washed before or after treatment or the dried gel is washed. The treatment may be carried out by passing heated gas satd. with water vapor over the hydrogel immersed in water, or by circulating heated air repeatedly over the hydrogel on perforated trays in a drying chamber, or by soaking the washed hydrogel in strong  $\text{H}_2\text{SO}_4$  which reacts with the water to raise the temp.

**Catalytic gels.** THE SILICA GEL CORP. Fr. 650,257, Mar. 1, 1928. Porous gels, pptd. by an acid such as  $\text{H}_2\text{SO}_4$ , are impregnated with a catalytic metal or compd. thereof by charging the gel with a gaseous compd. having a reducing action and treating it with a soln. of a compd. of the catalytic metal which may be Pt, Ag, Ni, Cu or Fe and the reducing gas may be  $\text{SO}_2$ , CO or  $\text{H}_2\text{S}$ . Cf. 23, 941.

**Adsorbent for filtering and decolorizing.** HAROLD T. MAITLAND (to Sun Oil Co.). U. S. 1,711,504, May 7.  $\text{NH}_4\text{Al}$  sulfate is added to a sol. silicate with agitation and the materials are subjected to boiling until the reaction is substantially complete,  $\text{NH}_3$  is allowed to escape and  $\text{Na}_2\text{SO}_4$  is washed out and the product is dehydrated at a temp. of  $260$ – $540^\circ$ .

**Active charcoal.** JOSÉ M. M. MARQUÉS. Fr. 650,256, Mar. 1, 1928. Active charcoal is prepd. from peanut or almond shells, olive husks, grape seeds, residues from vinification and extn. of oils, etc., with or without a preliminary treatment followed by impregnation with mineral or org. salts and a carbonization in the absence of air or in an activating atm.

**Activating carbon.** JACQUE C. MORRELL. U. S. 1,712,930, May 14. The carbon is treated with an aq. soln. of a halogen-yielding material such as  $\text{HOCl}$  in the presence of a substance such as a carbonate which has a selective neutralizing action on the hydrogen halide which may be formed in the treatment.

**Activating carbon.** JACQUE C. MORRELL. U. S. 1,713,347, May 14. Particles of C of highly porous structure are subjected to the action of an aq. soln. of a halogen such as Cl.

**Preparation of metal catalysts.** I. G. FARBENIND. A.-G. Fr. 650,592, Mar. 8, 1928. As metal catalysts show max. activity at the temp. at which they have been formed, formation at a low temp. is sometimes important and this is secured by reducing the oxides or reducible salts by H in the presence of a catalyst. Examples are given.

**Refining kaolin, asbestos, chalk and like deposits.** PAUL C. H. ROHLAND. Ger. 475,040, Jan. 8, 1927. A continuous refining process is described in which the materials are stirred in water and the suspension is passed in turn through a mill, a separator for heavy impurities and dewatering means.

**Contact masses.** I. G. FARBENIND. A.-G. Fr. 650,237, Mar. 1, 1928. The mech. resistance of contact masses is increased by adding during their prepn. sol. salts of Mg and heating to drive off acid, or solid fragments of Zn, Al, Fe or like metals of the 2nd, 3rd or 8th group of the periodic system, or alloys or carbides of these metals may be used.

**Plastic masses.** MINERAL A.-G. Swiss 127,974, Mar. 15, 1927. Asphalt-like substance is prepd. from a dispersion of a vulcanized, non-bituminous substance with a bituminous material. Thus, 75 parts linseed oil are vulcanized with S at  $130$ – $150^\circ$ , and mixed with 100 parts molten vulcanized bitumen at  $150^\circ$ . After well-mixing, 200–400 parts sand or colored mineral are stirred in. Other examples are given.

**Plastic substances.** THE CELESCOR CO. Fr. 650,874, Mar. 15, 1928. Objects are molded by heating and pressing a powder contg. a finely divided cellulosic deriv. such as celluloid and a finely divided solid solvent such as acetanilide, methylacetanilide or camphor.

**Urea condensation products.** I. G. FARBENIND. A.-G. Fr. 651,035, Mar. 20,

1928. Solns. or suspensions of dimethylolurea, its derivs., substitution products or polymers are condensed with the aid of buffer mixts. by heating, the H-ion concn. being  $p_H = 4-7$ . Thus, a soln. or aq. suspension of dimethylolurea, to which is added a mixt. of mono- and di-Na phosphates, is caused to pass through a system of tubes heated to  $100^\circ$ , the outflow being regulated so that the soln. takes 5-10 mins. to pass through. The product is dried to a powder in a vacuum drying chamber. A suspension of dimethylolurea in iso-BuOH, contg. mono- and di-Na phosphate, is passed through a system of tubes heated to  $100-110^\circ$ , and the formed soln. is neutralized with  $Na_2CO_3$ . Fr. 651,036 describes the prepn. of condensation products of methylolureas with polyatomic alcs. which contain more than one free OH group. Thus, dimethylolurea in suspension in glycerol is heated with K oxalate to  $100-110^\circ$ . On neutralization a stable, very viscous product is obtained. Dimethylolthiourea or a mixt. of dimethylolurea and dimethylolthiourea may be used. Dimethylolurea is incorporated in a soln. of polyglycolic ether and tartaric acid and heated for a short time to  $100^\circ$ , giving a viscous product miscible in all proportions with water, and serving as a source for artificial horn or casein.

**Condensation products of aldehydes and phenols.** I. G. FARBERNIND. A.-G. Fr. 651,646, Mar. 23, 1928. Aldehydes are condensed with *p*-chlorophenol or *p*-bromophenol or with their derivs. contg. indifferent substituents to form products which are used for *moth-proofing wool and the like*. In example (1) 2,4-dichlorophenol is dissolved in glacial AcOH and  $H_2SO_4$ ,  $CH_2O$  is added and the mixt. heated to  $50-70^\circ$  for some hrs. The product is pptd. by pouring into water; (2) *p*-chlorophenol is condensed with *p*-chlorobenzaldehyde, and (3) with *o*-sulfobenzaldehyde.

**Drying casein.** ANTOINE GUILLAUME. Fr. 651,334, Feb. 21, 1928. A series of endless bands are mounted in a chamber one above the other and in staggered relationship so that the casein travels down in a sinuous path.

**Agar.** JOHN BECKER. U. S. 1,712,785, May 14. After preliminary soaking and washing, each lb. of seaweed is mixed with 1 gal. of water and cooked under a constant temp. and pressure and the liquor is drawn off, filtered with "filter mass" and charcoal, agitated, evapd. to remove excess moisture, congealed to a temp. of about  $22^\circ$ , sized and frozen; the ice is then melted, excess water is drawn off by vacuum and the material is dehydrated (suitably by a warm air current).

**Mucilages.** AMAND BRAUN. Fr. 651,552, Sept. 15, 1927. Substances such as marine algae, carob seed or moss used for making mucilages, *e. g.*, for basic dyes, are first heated to  $80-130^\circ$ , with or without steam.

**Filtering material.** HENRY BLUMENBERG, JR. U. S. 1,713,250, May 14. A filtering material suitable for treating hydrocarbon oils, water or sewage or for other uses as a purifying, decolorizing and oxidizing agent comprises Al sulfate,  $Ca(OC_2)_2$  and an inert cellular material such as diatomaceous earth. U. S. 1,713,251 specifies a similar mixt. contg. a sol. sulfate of an alkali-forming metal such as  $Na_2SO_4$  instead of Al sulfate.

**Heat-conveying medium.** GES. FÜR KÄLTECHEMIE G. M. B. H. Ger. 475,080, Nov. 18, 1927. A purified aq. soln. of  $CaCl_2$  and  $AlCl_3$  is used as a heat-conveying medium, particularly in central heating installations.

**Composition for dampening sound and vibration in building construction.** M. HAHN and K. B. EISENBERG. Brit. 299,543, Aug. 9, 1927. Mixts. are formed of materials such as mineral oil or other suitable non-drying oil 25, clay or loam 65 and a dust-like filler, *e. g.*, alumina 10%.

**Cleaning polishing-wheels formed of abrasive material bonded by glue.** JOHN J. CUNNINGHAM (51% to Melrose G. Kopf). U. S. 1,712,751, May 14. In order to clean polishing-wheels of this character, the glue binder is softened (suitably by use of steam) at the periphery of the wheel and the latter is rotated to throw off material from the surface by centrifugal force.

**Tempering shoe parts impregnated with stiffening substance.** EDWARD H. WESTPHAL (to United Shoe Machinery Corp.). U. S. 1,712,600, May 14. Shoe parts, such as toe stiffeners formed of fabric impregnated with a stiffening substance such as celluloid, are treated with a volatile liquid, *e. g.*, an alc.-acetone mixt. in which the stiffening substance is sol. and are placed in layers between felt or other material also treated with the liquid.

**Shoe-stiffening material containing a cellulose ester.** STANLEY P. LOVELL (to Celastic Corp.). U. S. 1,711,956, May 7. In softening a stiffening material such as a sheet of textile fabric contg. a cellulose ester compn. such as celluloid, the material is treated with a mixt. of liquids contg. 2 solvents, one of which is diacetone alc. and the other a substance such as EtOH having a b. p. below that of water, and the mixt. is

allowed to evap. so that the material treated will assume a strong, impervious, elastic form, regardless of moisture in the air.

**Liquid for use in hydraulic brake systems, etc.** A. T. K. TSENG (to Hydraulic Brake Co.). Brit. 299,370, Oct. 24, 1927. An oil such as castor oil is mixed with a higher alc. such as diacetone alc. KOH or Bu alc. KOH may be added. Cf. C. A. 23, 1230.

**Impregnated fabric suitable for brake and clutch facings.** JOHN A. HEANY. U. S. 1,712,002, May 7. Pulpy or fibrous stock such as asbestos, preliminary to the mfg. process for forming yarn or fabric, is mixed with a powdered impregnating material such as gilsonite which is afterward subjected to the action of benzine or other suitable solvent to diffuse the material throughout the fabric.

**Laminated material for gears, etc.** L. J. OLLESHEIMER (to Sprucolite Corp.). Brit. 299, 441, Oct. 28, 1927. In forming a material for pulleys, gears, etc., thin layers of wood with the grain crossing, after drying to a moisture content of not over about 2%, are coated with a binder such as casein glue, pressed lightly until an initial set occurs, and then the pressure is increased. Glue is used contg. insufficient moisture to bring the moisture in the final product up to that of normally kiln-dried wood. The drying may also be effected after the compressed block is made. Brit. 299,442 specifies use of a high initial pressure which is afterward lessened to permit some expansion or "spring back" of the compressed material during final setting.

**Filling teeth with gutta percha.** IRVING KULIK. U. S. 1,711,952, May 7. Dry gutta percha is introduced into the cavity to be filled and the gutta percha is then subjected to the action of a solvent such as  $\text{CHCl}_3$  to cause its swelling or expansion. Ammoniacal silver nitrate and  $\text{CH}_2\text{O}$  soln. may be conjointly used.

**Fire extinguishers.** LUCIEN E. P. FOUCAUD. Fr. 650,133, Aug. 12, 1927. Anhydrous  $\text{CuSO}_4$  is added to dry powders used for fire extinguishing as an indicator by its color as to whether the power is dry or has become damp.

## 19—GLASS, CLAY PRODUCTS, REFRACTORIES AND ENAMELED METALS

G. E. BARTON, C. H. KERR

An apparatus designed by A. G. Gagarin for the determination of the plasticity of clay. N. K. LAKHTIN. *Trans. State Exptl. Inst. Silicates* (Moscow) 1927, No. 21, 25-7. The clay sample *AA* is placed between the clamps *BB*, which in construction are similar to those of the Michaelis app. Because of the weakness and flexibility of the clay, the sample *AA* is underlaid by a platform *CC*, which can be moved apart. In order that the clay will not stick to the platform, parchment paper or powder is put on it. The platform rests on a carriage with five rollers *R*, over which both parts of the platform may easily move when the clay sample becomes elongated. To one of the clamps a dynamometer *F* is attached. To the other clamp a screw *H* is attached. To det. the stretching of the sample a special contrivance is made. With the aid of a light

ray it gives automatically the deformation (stretching or elongation) of the clay sample and the increase in the tension, which stretches it. This contrivance consists of 2 spiral weak springs *P*; one is a left- and the other is a right-hand spiral. Both springs have one end attached to the joint-pins *S*, which are placed in the "heads" of the clay sample; the other ends of the springs are fastened together. At the place of their junction *T* a light mirror *Z* (0.5 mm. square) is fastened, which reflects the light ray falling on it from the light of the lamp *L* (prepd. specially for projection purposes). To receive the light ray there is a curved surface *V* on the carriage. On this surface a paper sensitive to light is placed. By increasing the tension of the dynamometer spring without changing the length of the clay sample, the light ray will give a straight line at

the lower edge of the sensitive paper. If the sample becomes deformed with an increase in the strain on the spring of the dynamometer, both spiral springs are stretched equally; because of that the mirror will not move over the axis of the sample, but it will turn because of the stretching of the springs, which causes the springs to unwind equally. Under such conditions the light ray will give a straight line along the left-hand edge of the sensitive paper. By a simultaneous increase of the tension on the dynamometer (increase of the pulling strains in the clay sample) and of the deformation of the sample, the light ray will give a curve indicating the information desired.

J. S. JOFFE

The relation of the composition of glass to its optical constants. III. T. TAKAMATSU. Osaka Ind. Research Inst. *Repts. Imp. Ind. Research Inst., Osaka, Japan* 9, No. 12(1929).—Optical consts. of Na-K glass having the compn. of  $x/2\text{Na}_2\text{O} \cdot x/2\text{K}_2\text{O} \cdot y\text{CaO} \cdot 6\text{SiO}_2$  have been detd. When  $\text{SiO}_2$  and CaO are kept const., the value of  $n_D$  increases regularly with the increase of the sum of the mol. concn. of  $\text{Na}_2\text{O}$  and  $\text{K}_2\text{O}$ , the av. increase being 0.0010 per 0.1 mol. If the sum of the mol. concn. of  $\text{Na}_2\text{O}$  and  $\text{K}_2\text{O}$  is below 2.4 mol. against 6 mol.  $\text{SiO}_2$ , the change of  $n_D$  is in a straight line. The increase of the total dispersion is proportional to the increase of the sum of mol. concn. of  $\text{Na}_2\text{O}$  and  $\text{K}_2\text{O}$ , the av. increase being 0.000059 per 0.1 mol. The change of  $\gamma((n_D - 1)/(n_F - n_C))$  is inversely proportional to the sum of the mol. concn. of  $\text{Na}_2\text{O}$  and  $\text{K}_2\text{O}$ , the av. decrease being 0.30 per 0.1 mol. increase. When  $\text{SiO}_2$ ,  $\text{Na}_2\text{O}$  and  $\text{K}_2\text{O}$  are kept const., the change of  $n_D$  is regular; if the sum of  $\text{Na}_2\text{O}$ ,  $\text{K}_2\text{O}$  and CaO is below 2.4 mol. against 6 mol.  $\text{SiO}_2$ , the change of  $n_D$  is in a straight line, the av. increase being 0.0027 per 0.1 mol. CaO. The av. increase of the total dispersion is 0.000066 per 0.1 mol. increase in CaO. The change of  $\gamma$  is inversely proportional to the increase of CaO, the av. decrease being 0.16 per 0.1 mol. increase in CaO.

F. I. NAKAMURA

Corrosion of crucible in glass manufacturing. MASAJIRO WATATANI. *Repts. Imp. Ind. Research Inst., Osaka, Japan* 9, No. 6, 1-31(1928).—Twenty-one kinds of crucibles were made by combination of domestic and foreign clay and minerals; the degree of corrosion caused by the action of  $\text{Na}_2\text{O}$ -PbO or  $\text{K}_2\text{O}$ -PbO glass was detd. by the macroscopical examn. of the crucible and also by the analyses of the glass, after a definite time interval of heating with molten glass. The corroding action of  $\text{Na}_2\text{O}$ -PbO glass was greater than that of  $\text{K}_2\text{O}$ -PbO glass. The higher the temp. of heating of the crucibles previous to the pouring of the molten glass, the greater was the corrosion. Addn. of feldspar to the ingredients in the prepn. of the crucibles increased the resisting power of crucibles to corrosion. The samples made from German clay had a greater resistance to corrosion than those made from domestic clay.

NAO UYEH

Temperature measurement in the glass-melting furnace. ANON. *Spechsaal* 62, 273-4(1929).—A radiation pyrometer is described, which compensates for the temp. of the instrument by utilizing two symmetrically placed and similar thermal junctions, one of which is exposed to the light radiating from an opening in the furnace. These junctions are connected so that the thermal effect due to the temp. of the instrument is zero.

C. H. LORIG

Natural rocks in the making of bottle glass. I. I. KITAIGORODSKII AND S. V. RODIN. *Trans. State Exptl. Inst. of Silicates (Moscow)* 25, 62 pp.(1928).—Because of the scarcity of soda, nepheline and trachyte rocks were considered as substitutes in glass batches. Besides trachyte the batch consisted of sand and either chalk, dolomite or barite. Devitrification occurred in factory melts when the glass was held at the working temp. A batch of trachyte 85%, sand 5% and the remainder chalk, did not devitrify; it passed specifications for green bottle glass. In some expts 1-2% sulfate was added. The melting time and temp. of these glasses are greater than the customary glass; the working range is shorter.

A. E. BADGER

The behavior of glass towards some aqueous alkali solutions of normal concentration at high temperatures. FRITZ FRIEDRICH. *Spechsaal* 61, 713-5, 730-1, 751-4(1928).—The loss of wt. and the alkali requirement were detd. for 5 types of glasses and  $N$  alkali solns. in the temp. range of 100° to 300°. The glasses were exposed to the liquid phases of the solns. All data are summarized in tables and curves. Under the influence of alkali hydroxides and  $\text{H}_2\text{O}$ ,  $\text{Al}_2\text{O}_3$ -rich glass devitrifies.  $\text{Al}_2\text{O}_3$  in glass promotes its resistance toward alkali hydroxides. Alkali carbonates attack  $\text{Al}_2\text{O}_3$ -rich glass more rapidly than the hydroxide. Glasses of high  $\text{B(OH)}_3$  content dissolve in  $\text{H}_2\text{O}$  to the extent of 48%.

C. H. LORIG

The application of nepheline syenites of the Murman coast in the glass industry. V. V. VARGIN. *Trans. Ceramic Research Inst. (Moscow)* 15, 61 pp.(1929).—The utilization in the glass industry of large beds of nepheline syenite (15-16% alkali), which are found on the coast of Lapland, is suggested as a substitute for soda in glass batches.

Lab. melts of 3 kg. each were tested as regards easy melting and working qualities, tendency to devitrify and ability to withstand tests accorded to bottle glass. Conclusion: Nepheline may be used in glass batches up to an amt. which gives less than 15%  $\text{Al}_2\text{O}_3$  in the glass. The  $\text{SiO}_2$  should be not less than 58% and  $\text{SiO}_2 + \text{Al}_2\text{O}_3$  not less than 70%. The remaining batch constituents besides nepheline are sand and lime. The addn. of 0.3–0.5% sulfate is advisable in order to shorten the plaining period.

A. E. BADGER

**The devitrification of glass.** P. VILLARD. *Compt. rend.* 188, 969–72(1929).—A study was made of the roughening of glass surfaces such as occurs in ordinary lab. glass blowing. The frosted surface sometimes observed on drawing out a piece of glass is due to the Reaumur effect, *i. e.*, the sepn. of the glass into 2 phases. Most of the other devitrification is caused by the corrosive action of the blow torch flame. Expts. are described in which a glass tube was heated in an elec. furnace and the gases present in the flames were passed through the tube. None of them alone caused devitrification, but with  $\text{H}_2$  contg. 1% of  $\text{O}_2$  and with  $\text{H}_2$  activated by an elec. spark, the glass was attacked with the liberation of Na, showing the devitrification to be due to the action of at. H. Glass roughened by flame action can be repolished by holding in the outer region of the flame. Bohemian (K) glass can be worked with a blow torch if a little  $\text{O}_2$  is added to the air.

**Annealing of glass from the point of view of factory operation.** E. A. COAD-PRYOR. *J. Soc. Glass Tech.* 12, 204–13(1928).—A general discussion of efficiency methods which tend to simplify, cheapen and make fool proof the annealing practice.

H. F. K.

**Expansion and tensile tests on glass house refractories.** J. F. HYSLOP, R. F. PROCTOR AND H. C. BIGGS. *J. Soc. Glass Tech.* 12, 190–204(1928).—Results of the expansion tests above 1000° grouped the  $\text{SiO}_2$ - $\text{Al}_2\text{O}_3$  refractories into 3 classes (a) those of rapid and large contraction, due to lightly or moderately burned material; (b) those of decreased rates of expansion, due to hard burnt material; (c) those of uniform rates of expansion. The tensile test is considered more useful than most other phys. tests because it reveals more clearly the effects of high flux iron oxide content, of high porosity, of low percentage of  $\text{Al}_2\text{O}_3$ , of the gradation of grog and shows the quality of cohesion between crystals and matrix.

H. F. KRIEGE

**The clay studies of the Orsam Laboratories.** EBERHARD ZSCHIMMER. *Sprechsaal* 62, 165–8, 257–60(1929).—The relative viscosity of moistened clay was selected as a criterion of its plasticity and used to det. the amt. of tempering  $\text{H}_2\text{O}$  required. At 1150° soda attacks acid clays much more rapidly than basic clays. Clays are strongly corroded in Glauber salts at temps. above its dissociation temp.; the acid clays are more resistant.

C. H. LORIG

**Lime as used in sand-lime brick.** D. M. GRAY. *Cement Mill and Quarry* 34, No. 4, 18–9(1929).—The two principal processes used in manuf. of hydrated lime are discussed, namely, Clyde and Kritzer systems.

E. I. S.

**Haircracks and exfoliation in faience.** A. J. EDWARDS. *Sprechsaal* 62, 241–3 (1929). Uncombined  $\text{SiO}_2$  in the body tends to increase its coeff. of expansion.  $\text{SiO}_2$  and  $\text{B}_2\text{O}_3$  when dissolved in the glaze lowers its coeff. of expansion, but if used in excess, tends to devitrify the glaze and make it cloudy.

F. V. JOHNSON, JR.

**Heat transfer through ceramic materials.** MAX JAKOB. *Ceram. Age* 11, 121–30 (1928).—The theory of heat transfer is discussed in detail with mathematical derivation of formulas. Methods of detg. heat cond. of ceramic materials and measurement of variable heat flow are given. Various influences which affect the heat cond.,  $K$ , are compn., sp. gr., porosity, moisture, temp. and structure of the material. 10%  $\text{MgO}$  causes 100% increase of  $K$ . 5%  $\text{MgO}$  has no effect. 10%  $\text{CaO}$  causes 50% decrease of  $K$ . A 25% increase in  $\text{Al}_2\text{O}_3$  reduces  $K$  to one third its original value. Further increases up to 50% have no effect. For every 10% increase in  $\text{SiO}_2$ ,  $K$  decreases only 4%. The  $K$  of  $\text{SiO}_2$  brick is more than 50% greater than the  $K$  of fireclay brick of equal d. In general,  $K$  increases as the sp. gr. increases. Abs.  $K$  is low for amorphous materials and high for cryst. materials. For amorphous materials  $K$  increases with temp. For cryst. materials  $K$  decreases with temp. A large number of ceramic materials and refractories are tabulated with their sp. gr. and heat cond.

**Refractories for the pottery industry. W. EMBRY. *Trans. Ceram. Soc. (Eng.)* 25, 111-26(1926).—A general survey is made of the requirements of refractories used in the construction of intermittent, continuous and frit kilns, and in the manuf. of supports for ware in the kiln.**

B. C. A.

**Steel-making refractories. I, II. E. R. WALKER. *Chem. Eng. Mining Rev.* 21, 93-8, 133-47(1929).—Methods of testing are given for refractoriness, apparent porosity, contraction or expansion, crushing strength, refractoriness under load, spalling and slagging. Graphs are shown giving refractoriness, heat cond. and thermal expansion of fireclay and silica bricks under load. The total impurities in clays should not exceed 4%. The analyses, porosity and apparent sp. gr. of two Australian-made sleeve bricks are:  $\text{SiO}_2$  72.026 and 75.04;  $\text{Al}_2\text{O}_3$  24.64 and 20.74;  $\text{Fe}_2\text{O}_3$  1.59 and 2.76%;  $\text{CaO}$  trace and nil;  $\text{MgO}$  0.41 and 0.41%; ignition loss 0.48 and 0.10; porosity 21.40 and 27.65; apparent sp. gr. 2.02 and 1.91. The analysis and porosity of stoppers most generally used are  $\text{SiO}_2$  47.13 and 47.01;  $\text{Fe}_2\text{O}_3$  3.45 and 5.40;  $\text{Al}_2\text{O}_3$  20.13 and 27.01;  $\text{CaO}$  0.14 and 0.17;  $\text{MgO}$  0.09 - 0.20; C. 29.10 and 19.77; porosity 30.25 and 33.15. Silica and neutral refractories are discussed.**

**Electric induction furnace suitable for glass manufacture.** H. GEORGE. Brit. 299,393, Oct. 25, 1927. A metal bath is used with which the glass is in contact. Various structural features are specified.

**Rotary vertical leer for annealing glassware.** ROBERT GOOD (to Hazel-Atlas Glass Co.). U. S. 1,712,205, May 7. Structural features.

**Glass press.** GLASFABRIK A.-G. (Alfred Wahl, inventor). Ger. 475,141, July 5, 1925.

**Treating glass objects.** DEUTSCHE SPIEGELGLAS A.-G. Ger. 475,001, April 27, 1927. Glass objects are given a light-diffusing surface without substantial loss of transparency by first roughening the surface in a known manner and then applying heat until the roughened surface has at least begun to soften.

**Composite glass.** SOC. ANON DES MANUF. DES GLACES ET PRODUITS CHIM. DE SAINT-GOBAIN, CHAUNY ET CREY. Fr. 650,155, Aug. 18, 1927. In composite glass wherein 2 sheets are cemented to an intermediate sheet of org. materia of approx. the same index of refraction, the faces of the sheets contacting the org. material are roughened by grinding.

**Reinforced glass.** JACQUES DUCLAUX. Fr. 651,157, Aug. 23, 1927. In making compd. transparent sheets by coating 2 glass sheets successively with gelatin and nitrocellulose, and uniting by pressure, the coating of gelatin is dried by dipping in a bath of EtOH, MeOH, PrOH, BuOH, or acetone or sol. ketone, or of a mineral or org. dehydrating agent. Adhesion may be increased by emulsifying a soln. of nitrocellulose, cellulose ester or ether, or gums, waxes, oils, etc., with the gelatin, or by adding to the gelatin an aq. soln. of a substance capable of dissolving celluloid. Cf. C. A. 23, 2798.

**Glass for electric insulation.** PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN M. B. H. (Max Thomas, inventor). Ger. 475,135, Aug. 2, 1925. A glass of good insulating properties comprises  $\text{SiO}_2$ , an alkali metal oxide, at least 5% of  $\text{Fe}_2\text{O}_3$ , and at least one other oxide of a bi- or trivalent metal. A suitable compn. is  $\text{SiO}_2$  67,  $\text{K}_2\text{O}$  3,  $\text{CaO}$  10,  $\text{BaO}$  10, and  $\text{Fe}_2\text{O}_3$  10%.

**Coating electric lamp bulbs or other glass articles.** M. PIPKIN (to British Thomson-Houston Co., Ltd.). Brit. 299,477, Oct. 28, 1927. Articles which become heated in use are coated with a mixt. comprising castor oil, a resinous substance (suitably shellac), a pigment and a solvent such as alc. By drying at  $160^\circ$  the coating is suitably matured, presumably by reaction between its ingredients.

**Translucent incandescent lamp bulbs or other hollow glass articles.** MARCELLO PIRANI (to Patent-Treuhand-Ges. für elektrische Glühlampen). U. S. 1,713,394, May 14. Finely pulverized glass is sintered and the end of a glass tube is melted onto a "gob" of the sintered glass; the bulb or like article to be formed is blown through the tube while quickly heating the "gob" to blowing temp. to maintain uniform distribution of the small air or gas pockets within the mass.

**Manufacture of hollow glass bodies.** PATENT-TREUHAND-GES. FÜR ELEKTRISCHE GLÜHLAMPEN M. B. H. Ger. 475,140, July 17, 1927. Mech. and manipulative details.

**Manufacture of double-walled hollow glass bodies.** GLASFABRIK SOPHIENHÜTTE RICHARD BOEK G. M. B. H. Ger. 475,385, July 14, 1925. Manipulative features.

**Waterproofing bricks, etc.** EDMOND LOMBARD. Fr. 650,301, Mar. 2, 1928. A soln. of a K or Na soap is used for waterproofing bricks, etc.

**Cover for the fire space of ceramic and like kilns.** ALEXIS C. RAGOUCY. Ger. 475,495, June 9, 1926.

**Continuous tunnel kiln suitable for burning ceramic ware.** HALVER R. STRAIGHT (to Ethel H. Straight). U. S. 1,711,910, May 7. Structural features.

**Refractory material.** JAMES M. LAMBIE and DONALD W. ROSS. U. S. 1,712,005, May 7. A batch mixt. for forming refractory articles such as crucibles, "plastic fire brick," or glass-melting pots contains sufficient finely divided cyanide to counteract the shrinkage, during firing, of the other ingredients (which may include clay and corundum).

**Refractory substances.** ALBERT WAGEMANN. Fr. 650,536, Mar. 7, 1928. See Brit 286,677 (C. A. 23, 495).

**Manufacture of hollow bodies, open at one side, from quartz and like refractories.** G. FARBERIND. A.-G. (Fritz Doerfinkel and Martin Schliemann, inventors). Ger.

475,142, Sept. 17, 1926. The refractory is fused in the mold around a core constituting an elec. heating resistance.

**Refractory and insulating material.** LA STÉATITE FRANÇAISE. Fr. 650,847, Mar. 14, 1928. Kaolin 1, natural steatite 3 and flux 1 part, with a little clay, are ground in the presence of water, dried, molded and backed at about 1500°.

**Porcelain-like insulating composition.** J. L. A. HILBRENNER. Brit. 299,408, July 26, 1927. A compn. for making insulating parts of spark plugs, heating and lighting devices, etc., is formed with fat clay, kaolin and oxides of Zr and Al; a flux may be added such as ZnO or a frit composed of MgO, ZnO and Al<sub>2</sub>O<sub>3</sub>, may be ground together in a wet state and heated quickly to sintering temp.

**Electric resistance heated furnace suitable for use in enameling, etc.** ALLGEMEINE ELEKTRICITÄTS-GRS. (to International General Electric Co.). Brit. 299,398, Oct. 25, 1927. Structural features.

## 20—CEMENT AND OTHER BUILDING MATERIALS

J. C. WITT

A few thoughts regarding the cement service laboratory. EDGAR S. ERNST. *Rock Products* 32, No. 8, 72-4(1929).—The role of the service lab. in bringing about more intelligent use of cement is pointed out.

**Microscopic analysis of cements.** A. LOPEZ FRANCO. *Rev. obras publicas (Madrid)* 73, 76-8(1929).—Notes on lab. work undertaken at School of Roads. E. I. S.

**The setting of cement. III.** HERMANN GESSNER. *Kolloid-Z.* 47, 160-75(1929), cf. C. A. 23, 1732.—A study has been made of the loss in wt. for H<sub>2</sub>O in cement during hardening. Expts. were carried out over many concns. of H<sub>2</sub>SO<sub>4</sub> starting with a fixed initial ratio of H<sub>2</sub>O to cement. Data were obtained on change of wt. with time extending over periods as much as 200 days. One set of expts. was made with ordinary portland cement and another in which no gypsum was present. The results in the two cases are practically alike. A hydrate especially noticeable with freshly set cement is shown in both cases at about 10.4 mm. Hg which slowly disappears with age. The practical application of vapor-pressure isotherms is discussed. Just how important gypsum content is compared to other factors such as grain size cannot be detd. by these expts. only. Hydration is evaluated from vol. change with aging. Greatest contraction occurred after 2 days' setting. These results accord with those from isotherm detn.

RAYMOND H. LAMBERT

**Temperature rise observed on solidification of mixtures of portland cement and calcium chloride.** SHICHIRO UCHIDA. Sendai Higher Tech. School. *Mem. Sendai Higher Tech. School* 6, 381-7(1928); cf. C. A. 22, 673.—U. measured the time required for the solidification and the accompanying temp. rise of portland cement mixed with 1, 2, 2.5, 3, 5, 7, 10 and 20% CaCl<sub>2</sub>; similar measurements were made with 3:1, 2:1, 1:1 and 1:3 mortar prepd. by mixing 3% by wt. of CaCl<sub>2</sub> with cement. The increase of the CaCl<sub>2</sub> content lessens the time of solidification, the heat evolution increasing irregularly. With mortar, the temp. rise is the greater the greater the cement content.

K. SOMEYA

**Effect of adding various percentages of diatomaceous earth to portland cement mixtures.** ALTON J. BLANK. *Rock Products* 32, No. 6, 81-2(1929).—Increased strengths of 1-3-6 and 1-2½-5½ concrete resulted from the replacement of up to 15% of the cement by diatomaceous earth with cements rather high in free CaO (exact amts. of free CaO not given). Similar tests on a cement low in free CaO showed a reduction in strength with replacement by diatomaceous earth of part of the cement.

RAYMOND WILSON

**Effect of aging on the grinding resistance and cementing value of portland cement clinker.** L. N. BRYANT. *Rock Products* 32, No. 8, 64-5(1929).—The grinding resistance of a given clinker varies in direct proportion to its loss on ignition. A fresh high-lime clinker has a lower grinding resistance than a fresh low-lime clinker. Grinding resistance of the high-lime clinker increases with aging more rapidly than that of a low-lime clinker. The cementing properties of a low-lime clinker are less affected by aging than those of a high-lime clinker. These conclusions are based on tests of several clinkers, reduced when fresh to a size between 8- and 10-mesh and stored outdoors for periods up to 10 months. Grinding resistance was measured by the 200-mesh fineness produced under fixed conditions in a lab. tube mill.

A simple titration method for determining the absorption of fine aggregate. J.

C. PEARSON. Lehigh Portland Cement Co. *Rock Products* 32, No. 10, 64-5(1929).—Water is added from a buret to a 200 g. sample of dry aggregate in a 500 cc. Erlenmeyer flask. The flask is rolled and shaken to insure complete distribution of the water. The point at which the sand persists in adhering to the glass is the end point. Accuracy of the order of 0.05% is attained with clean sands. RAYMOND WILSON

Basic principles of concrete making. F. R. McMILLAN. Portland Cement Assoc., Chicago. I. Cement paste the basis of concrete quality. *Eng. News-Record* 102, 580-3(1929). II. Strength and watertightness—supporting data. *Ibid* 625-32. III. Combining aggregates with paste to make workable concrete. *Ibid* 673-9. IV. Application to specific conditions. *Ibid* 705-9. V. Importance of proper construction methods. *Ibid* 748-52.—An exceptionally complete presentation of the fundamental principles of concrete-making, theory and practice, and of the various factors affecting the quality of the product, with an abundance of supporting exptl. data, for details of which the original must be consulted. The application of these principles to the production of concrete to meet specific requirements of strength, durability, watertightness, etc., is discussed at length. R. E. THOMPSON

Tests of truck-mixer concrete. A. R. HIRST. *Eng. News-Record* 102, 798 (1929).—Three test runs of a truck mixer (Bickel patents) were carried out. Conclusions: (1) The speed of revolution, within the possible limits of the device, does not greatly influence the compressive strength of the concrete. (2) Very dry concrete can be very thoroughly mixed and completely discharged. (3) In general, compressive strength increases with the no. of revolutions. (4) The slump of the concrete decreases with the no. of revolutions. (5) There is no reduction in compressive strength due to long retention in the cylinders up to at least the time of initial set. R. E. T.

Will a fifth ingredient assure durability [of concrete]? ALFRED H. WHITE. *Concrete* 34, No. 3, 15-6(1929).—A brief discussion of "inert" admixtures, water-repellent materials and soluble addns. RAYMOND WILSON

The stability of chert. HERBERT F. KRIEGE. *Rock Products* 32, No. 9, 50-3 (1929).—There is apparently no microscopic property of cherts which serves to identify those of poor resistance to weather when used as concrete aggregates. The factors which seem to contribute to instability of certain cherts are microscopic irregularities of texture and the presence of firmly imbedded foreign crystals with different phys. properties. RAYMOND WILSON

Determining the causes of failure in brick work construction. R.D. DONATH AND H. LEOPOLD. *Chem.-Zig.* 53, 277-9(1929).—The investigation by chem. means of the causes of failure of brickwork construction showed (1) high Cl and NO<sub>3</sub> content of water used in making mortar, thereby causing the reaction  $\text{CaO} + 2\text{NaCl} + \text{CO}_2 = \text{Na}_2\text{CO}_3 + \text{CaCl}_2$  to occur; (2) too high a ratio of Al<sub>2</sub>O<sub>3</sub> and Fe<sub>2</sub>O<sub>3</sub> to SiO<sub>2</sub> in the sand employed, indicating contamination by silicates; and (3) the presence of sintered material enclosing free CaO in the lime used, which caused failure (unsoundness) in time. Especially must care be taken in using water coming from thickly populated districts to avoid sewage with its high Cl and NO<sub>3</sub> content. In the analysis 20 g. of mortar warmed with HCl (1:5) until CO<sub>2</sub> evolution stopped was examd. by ordinary procedure, and the results were interpreted as above. W. C. EBAUGH

Preservation of stone by means of linseed oil. KARL WÜRTH. *Kunststoffe* 19, 27-8(1929).—Pure linseed oil is the best suited preservative for stone material. It forms a hard, waterproof coating, and is useful as an ingredient for mixing with porous binding agents. The linseed oil must be pure and free from slimy substances. This is accomplished by heating the oil to about 160°. The oil thus treated has the advantage of being brighter than raw linseed oil and dries better. B. HAMILTON

Wood pole practice—Western Union's pole preservative. P. J. HOWE. *Elec. Light and Power* 7, No. 4, 88, 90, 92, 96, 122, 124, 126(1929).—Zn meta-arsenite was used. E. I. S.

Diatomaceous earth [as admixture in concrete] (HASTINGS) 18. Marine wood borers (WHITE) 11L. Sulfoaluminates of Ca (LARCH, *et al.*) 6. Wood-destroying fungi. I. *Polyporus hispidus* (NUTMAN) 11D. P and cement (Fr. pat. 650,412) 18.

**Cement composition.** E. BARNHART (to A. Metherell). Brit. 299,427, Oct. 26, 1927. A cement concrete with a glazed surface and a vitreous content distributed throughout the mass is formed by adding  $MgCl_2$ ,  $CaCl_2$ , Al sulfate and  $Na_2SO_4$  to the gaging water. An alum, preferably with further addn. of  $MgSO_4$ , may be used instead of Al sulfate.

**Hydraulic cement.** ROBERT DeLUCE. U. S. 1,713,172, May 14. An aq. mixt. comprising lime, silica and alumina in portland-cement forming proportions is digested at a temp. of at least  $100^\circ$  under superatm. pressure and with violent agitation until an insol. Ca Al silicate is formed and the latter is subsequently heated to the point of incipient fusion.

**Hydraulic cement composition.** LENNART FORSEN. U. S. 1,712,818, May 14. A granular "extender" such as sand or finely divided granite is added to portland cement together with burnt lime and the mixt. is ground for a sufficient time to convert the cement into such finely subdivided condition that it will react quantitatively with water. The product is of good strength.

**Porous concrete.** AEROCRETE (Foreign), LTD. and C. NICOL. Brit. 299,484, April 28, 1927. A small proportion of powdered Al or Zn is mixed with portland or similar cement and a material is also added capable of rendering the mixt. saponaceous in the presence of water and thus increasing the strength of the bubbles and also of retarding deterioration of the mixt. in storage. Stearin or a similar material may be used for this purpose.

**Determining the moisture content of aggregates to be used in concrete.** CHARLES S. JOHNSON. U. S. 1,712,621, May 14. A sample of aggregate is weighed in air, placed in water so that moisture in the aggregate combines with the water, and the dry-aggregate-content of the sample is weighed.

**Bituminous composition suitable for paving, etc.** CHARLES N. FORREST (to Barber Asphalt Co.). U. S. 1,711,727, May 7. Cold mineral aggregate such as broken stone and sand is mixed with cold flux and powdered bitumen in the presence of hydraulic cement and water. The product may be used either for pavement foundation layers or wearing surfaces.

**Bituminous compositions for foundations for heavy loads, etc.** R. STEIN. Brit. 299,208, Aug. 8, 1927. A compn. suitable for supporting railway sleepers, heavy machinery, etc., comprises "Epure" 1, goudron 2, coal-tar pitch 2 and asbestos fiber 1 part, or a similar mixt. which may be reinforced with wire or wire mesh. The "Epure" used is a Trinidad asphalt freed from earthy impurities and the "goudron" is a Trinidad distn. product m.  $95-100^\circ$  and of good toughness.

**Apparatus for impregnating strips of roofing material or other fabric with asphalt or similar materials.** HENRY C. KOCH. U. S. 1,712,770, May 14.

**Laminated structural material comprising rubber and sheet metal.** ALGER G. MARANVILLE (to B. F. Goodrich Co.). U. S. 1,712,965, May 14. A layer of cellular hard rubber is united to a sheet of metal such as steel, Zn, Cu, brass or "duralumin" by a bonding layer of a heat-plastic reaction product of rubber such as may be formed by heating rubber with *p*-phenolsulfonic acid.

**Treating wood.** INTERNATIONAL FIREPROOF PRODUCTS CORP. Fr. 650,737, Mar. 10, 1928. Wood and other material is fireproofed and preserved by successive treatments with solns. of chlorides and boric acid and of metallic sulfates to ppt. insol. sulfates in the wood.

**Surfacing lumber.** WILLIAM C. GARDINER (to Satin Finish Hardwood Flooring Co., Ltd.). U. S. 1,711,884, May 7. Lumber having finished and unfinished surfaces contains a mixt. of denatured alc., turpentine and copal gum extending inwardly on the unfinished side, which serves to exclude moisture and other destructive agents.

**Preserving wood and similar materials.** ADOLF M. KOBIOLKE. U. S. 1,713,388,

May 14. The material is subjected to a vacuum in a kiln, preservative fluid such as creosote is forced into the kiln under air pressure, surplus treating fluid is withdrawn, the material is further subjected to a high vacuum and the vacuum is released to allow a sudden flow of air at atm. pressure to rush into the kiln and assist in evenly distributing the preservative fluid over and in the pores of the material.

## 21—FUELS, GAS, TAR AND COKE

A. C. FIELDNER

**Fuel analysis with a bomb and Orsat gas-analysis apparatus and the behavior of carbon dioxide-oxygen mixtures.** FRAN BOŠNJAKOVIĆ. Tech. Hochschule, Dresden. *Arch. Wärmewirt.* 9, 309–18(1928).—By detg. the temp. and pressure before and after firing in an ordinary calorimetric detn., and analyzing the bomb contents for CO<sub>2</sub> and O<sub>2</sub>, the ultimate analysis of the fuel may be detd. The necessary precautions are worked out. B. detd. the *departure from the perfect gas laws* of CO<sub>2</sub>-O<sub>2</sub> mixts. at 18–30° and 11–39 atm. by forcing the gases successively into a bomb, noting the pressures, and analyzing. ERNEST W. THIELE

**Firing of low-grade fine fuel.** KIICHIRO YAMAZAKI AND IZO TAKASE. Imp. Fuel Research Inst. *J. Fuel Soc. Japan* 8, 406–13(1929).—A preliminary report on an efficient combustion of low-grade fine fuel, such as colliery waste and coke breeze, using modified chain-grate stoker furnace. F. I. NAKAMURA

**Volatility in motor-fuel performance.** G. G. BROWN. *Oil & Gas J.* 27, No. 42, 107–8, 157–8, 161(1929).—The effective volatility of a motor fuel is the quotient obtained by dividing the wt. of fuel in the mixt. delivered to the cylinder by the wt. of fuel in the mist, supplied by the carburetor. Methods of detg. effective volatility are described. Motor fuels should possess an effective volatility of not less than 45–60% under conditions of use if the motor is to answer its throttle with a delay of not more than 4–5 seconds. Since about 30% of fuel is carried into the cylinder in the form of a mist, it is pointed out that the 30% point on the A. S. T. M. distn. curve appears to be the most important point indicating engine performance during the warming-up period or in cold weather. General conclusions reached are: (1) That part of the A. S. T. M. distn. up to 40–50% indicates effective partial volatility; (2) that part from 50 to 90% indicates the effective volatility under steady driving conditions. M. B. HART

**The sampling of coal.** E. S. GRUMELL. *Eng. and Boiler House Rev.* 42, 507–9(1929).—The theory of size-weight ratio has been critically examd. and the theory of errors is discussed. Conclusions which have been based on evidence derived from sampling of cars may be directly applied to taking of gross samples by substituting increments for cars, the two expressions being synonymous in argument. E. I. S.

**Coal testing and plant operation.** M. DOLCH. *Z. Oberschlesisch. Berg- u. Hüttenmannisch. Ver. Katowice* 68, No. 2, 64–72(1929).—Methods and equipment for rapid testing of coal for purpose of thorough fuel control. E. I. S.

**Rectangular graphs as applied to the proximate analyses of Chinese coals.** H. S. WANG. *Bull. Geol. Survey China* 7, 175(1928); *Fuel in Science and Practice* 8, 244–8(1929).—The chem. changes of Chinese coals during coalification are graphically represented upon several diagrams, fixed C, volatile matter and moisture being plotted on the ash-free basis. The classification of these coals according to their fixed C content (ash-free basis) shows close relation to their classification by Ashley's method. D. A. REYNOLDS

**Power consumption of coal mills.** P. ROSIN AND E. RAMMLER. *Arch. Wärmewirt.* 7, 54–7(1926).—Tests on Maxecon mills with air sepn. showed that (1) for a given setting of air blast, the fineness increased linearly as the load increased; (2) for different settings, the power consumption was independent of the fineness; (3) after deducting the power consumed at no load, the remaining power was proportional to the load. ERNEST W. THIELE

**The modern use of pulverized fuel in power-stations.** R. A. CHATTOCK. *Mech. World* 85, 371–3(1929).—Results obtained by Birmingham Elec. Supply Committee at Prince's elec. power station, Nchells, with Lopolco pulverized-fuel equipment fitted to six Vickers-Spearing water-tube boilers, also results obtained with Simon-Carves pulverized-fuel-fired boilers are compared with previous results. E. I. S.

**Progress in the use of pulverized coal as a fuel.** E. G. BAILEY. *Power House (Toronto)* 23, No. 6, 23–5(1929). E. I. S.

**Transportation of powdered coal.** L. KLEIN. *Arch. Wärmewirt.* 10, 177-80 (1929).—The packing of coal dust on transportation, which hinders the flow on discharging, consists in an interlocking of the irregularities of the surfaces of the particles, accompanied by an escape of air. Tests on a shaking machine, as well as in practice, showed a reduction in apparent vol. of 20-30%, most of which occurs in the first 20 km. of travel. A screw in the container helps to loosen the mass. Containers filled under vacuum will hold 25% more coal. ERNEST W. THIELE

**Evaluation of sieve analyses and characteristic curves for powdered coal.** P. ROSIN AND E. RAMMLER. *Arch. Wärmewirt.* 7, 49-53 (1926).—The results of sieve analyses are best expressed by a curve showing the relation between the total amt. passing a given sieve and the linear dimensions of the actual sieve openings. This makes it possible to interpolate and to compare results obtained with various sieve systems. ERNEST W. THIELE

**The behavior of the ash in powdered coal furnaces.** KURT BAUM. *Arch. Wärmewirt.* 10, 143-6 (1929).—Tests on the original ash, ash from the combustion chamber and fly ash showed that the last has the highest softening point. Water extrn. of the ash to remove alkalis raised the softening point. The compn. of the various ashes showed no decided trend. It is better to freeze the droplets of fly ash as soon as possible after they leave the flame, rather than to try to flux them. ERNEST W. THIELE

**Temperature gradient and heat storage in the brickwork of a powdered coal furnace.** K. RUMMEL, E. KUHN AND W. OELLERS. *Arch. Wärmewirt.* 10, 45-7 (1929).—Thermocouples inserted in the brickwork to varying depths showed that the fall in temp. near the inner wall was much greater than that calcd. This is due to the inward flow of air through the wall under the influence of the draft. Hence the heat loss from the wall is only 6% of that calcd. from the cond. of the brick, and the heat stored in the brick is cut in half. ERNEST W. THIELE

**Largest distilled-coal plant in the world opens at New Brunswick, N. J.** R. D. HALL. *Coal Age* 34, 229-30 (1929).—Outline description of a plant with annual capacity of 250,000 tons of coal, using K. S. G. process. Each ton of coal yields 1500 lb. semi-coke, 25 gal. tar, 3500 cu. ft. of rich coal gas with about 900 B. t. u. per cu. ft. and 2 to 3 gal. of light oil. E. I. S.

**Contribution to the study of the mechanism of the carbonization of coal.** E. AUDIBERT. *Fuel in Science and Practice* 8, 225-43 (1929).—The results of a series of lab. investigations are correlated with com. carbonization. On passing from a heating rate of  $1/3^\circ$  per min. to  $3^\circ$  per min. the initial softening temp. of coal is but little changed, whereas the solidification temp. was increased  $50^\circ$ . Softening temps. may be given without specifying the exact heating rate; they are generally about  $350^\circ$ . Solidification temps. range from  $425^\circ$  to  $550^\circ$ . The degree of fluidity which may be attained varies widely with different coals and cannot be predicted from their volatile content. Oxidation causes a decrease in this fluidity. Bubble formation within the fused mass, which causes the porous structure of coke, is independent of the fineness of the particles and is detd. by the fluidity attained during the plastic state. In general, cokes formed without swelling will be stronger the greater the fluidity attained, the more rapid the heating, the finer the original particles and the more nearly the density of the original mass approached the density of the coal. Although swelling increases the fluidity of the fused mass, thus tending to increase the coke strength, the formation of pores will actually reduce this strength. The agglutination of coke is shown by expt. to be independent of the passage of volatile matter during its carbonization; agglutination is therefore dependent only upon the softening of coal. These principles are applied practically to a series of lab. tests by which the com. coking characteristics of a coal may be predicted. D. A. REYNOLDS

**Low-temperature carbonization and the boiler house.** D. BROWNLEE. *Eng. Boiler House Rev.* 42, 522-4 (1929).—The situation today in the field of combined low-temp. carbonization and combustion for boiler-plant practice is discussed. E. I. S.

**Aqueous liquors from low-temperature carbonization of coal.** GILBERT T. MORGAN, DAVID D. PRATT AND ALFRED E. J. PETTER. *J. Soc. Chem. Ind.* 48, 89-93T (1929); cf. C. A. 22, 2828.—Distn. of low-temp. carbonization tar up to a vapor temp. of  $170^\circ$  gave in addn. to oil an aq. distillate to the extent of 7 gals./ton of tar. The latter was made alk. with NaOH and continuously extd. with  $\text{Et}_2\text{O}$  for 2 days; the ext. contained bases (I) and neutral oils (II); the aq. portion was satd. with  $\text{CO}_2$  and phenols (III) were extd. in  $\text{Et}_2\text{O}$ . The remaining aq. portion was concd. by distn., the distillate giving  $\text{NH}_4\text{Cl}$  upon treatment with HCl and evapn. The concd. liquor was acidified, filtered and extd., giving carboxylic acids (IV) in the  $\text{Et}_2\text{O}$  and resinic acids in the  $\text{H}_2\text{O}$ . The compn. of the crude liquor was (in g./l.): I, 0.1; II, 0.2; III, 9.2; IV,

3.7;  $\text{NH}_3$ , 5.5; total S, 2.1. In the distillate the compn. was I, 0.1; II, 1.6; III, 13.3; IV, 1.4;  $\text{NH}_3$ , 16.7; S, 3.4. I contained  $\text{PhNH}_2$ ,  $\text{C}_6\text{H}_5\text{N}$  and  $\alpha$ -picoline; IV contained  $\text{HCO}_2\text{H}$ ,  $\text{AcOH}$ ,  $\text{EtCO}_2\text{H}$ ,  $\text{PrCO}_2\text{H}$ ,  $\text{BuCO}_2\text{H}$ ,  $(\text{CO}_2\text{H})_2$  and resinic acids.

A. S. CARTER

**Progress in manufacture of synthetic anthracite—synthracite.** E. GEVERS-ORBAN. *Rev. univ. mines* 72, 93-8; *Génie civil* 94, 339(1929).—The low-temp. carbonization process for manuf. of anthracite briquets is described. Details of plant at Bonne Fortune, Belgium, are given and the cost of plant and economics of process are discussed.

E. I. S.

**Properties of coal for gas producer.** SEIJIRO UCHIDA. Imp. Fuel Research Inst. *J. Fuel Soc. Japan* 8, 399-404(1929).—In addn. to the common data based on analysis, calorimeter detn., etc., for the selection of the coal for gas producer S. discussed coal grading, caking power, fusing temp. of ash and reactivity of coke made at different temps.

F. I. NAKAMURA

**Prevention of heat losses by flue-ash deposits in steam boilers.** MAX BERGER. *1pparatebau* 41, 61-4(1929).—Descriptions of the stationary and portable "Starke" app. for removing deposits by blowing with steam which injects some of the flue gases.

J. H. MOORE

**Air preheating for grates.** WILHELM GUMZ. *Feuerungstech.* 17, 25-8, 38-43 (1929).—A general discussion of the effects of air preheating on grate firing is given. Reference is made to the caking of the coal, the danger of clinker formation, the effect on the grate bars, and the suitability of different types of grate. Deep fuel beds, non-coking coals, and underfeed stokers are most suitable.

ERNEST W. THIELE

**Savings in preheated combustion air.** A. EUGENE MICHEL. *Oil & Gas J.* 27, No. 42, 236, 257-8(1929).—The Ljungström air preheater reduced the stack loss to 6% as compared with 15.5%; 84.5% of the heat was utilized in producing steam as compared with 75% without the preheater.

M. B. HART

**The installation of heating with two gases and supplementary heating.** KARL LOBBECKE. *Feuerungstech.* 17, 61-4(1929).—A regulator is described which admits the correct amt. of air to a furnace in which two gaseous, liquid, or powd. fuels are being burned in varying proportions, at the same time recording the quantity of each gas and the air.

ERNEST W. THIELE

**Measurement of steam consumption of back-pressure and bleeder turbines.** E. JOSSE. *Arch. Wärmewirt.* 10, 169-73(1929).—Tests were made on several nozzles in which the throat velocity was equal to that of sound. In the formula  $G = ac\sqrt{ps}$ , where  $G$  is the quantity in kg./sec.,  $a$  the area in sq. m.,  $p$  the pressure in atm. and  $s$  the density  $\times 1000$  at the entrance, the value of  $c$  was found to be  $207 \pm 1$  for all cases.

ERNEST W. THIELE

**The briquetting plant of the Pacific Coast Coal Co.** G. N. CALKINS. *Min. Congress J.* 15, 285-6(1929).—This plant has been in continuous operation for 15 years. Seven stages of manuf. are outlined. High efficiency is maintained by annual overhauling during slack seasons.

E. I. S.

**Further results from plants for phenol recovery from ammonia liquors.** H. WIEGMANN. *Glückauf* 64, 605-6(1928).—From the liquor were isolated 52% phenol, 9% *o*-cresol, 16% mixed cresols, 7.5% mixt. of cresols and xlenols. Inadequate washing only removes about 25% of the phenol but about 75% of the cresol. In another plant with better washing, this figure was 50-80%. The steam requirements, at first very great, can be cut down considerably, particularly through heat interchangers. If the washing app. works well, 25% benzene, calcd. on the amount of wash liquor, suffices to give a satisfactory phenol removal. Only large-scale working can decide as to the respective merits of the benzene and alkali extn. methods. The first process has the advantages that it is very simple to work and does not require any additional chemical.

S. L. B. ETHERTON

**Disposal of ammonia liquors.** D. W. PARKES. *J. Soc. Chem. Ind.* 48, 81-6T (1929); cf. *C. A.* 21, 2549, 3449.—The cost of purification of virgin or spent  $\text{NH}_3$  liquors is balanced and a profit may be realized by recovery of phenol and catechol. The monohydroxy phenols (I) are recovered by a process of acidification, absorption in active charcoal and steam distn. The  $\text{NH}_3$  liquor is brought to  $p_H$  6-7 with mineral acid or almost to neutrality with  $\text{CO}_2$ ; after settling of the sludge, the liquor is passed through active C which absorbs I. When several absorbers are used in series, the 1st becomes satd before the others and may be cut out for distn. while a reserve is put in at the end of the series. In general, 3 absorbers contg. 50 lbs. of C each will care for 200 gals./hr. of liquor, one absorber being distd. every 5 hrs. During distn. 3 fractions are obtained: (1) everything until the distillate seps. into 2 layers ( $350^\circ$ ); (2) tar acids

(up to 650°); and (3) 650–800°. During the fraction (2) H<sub>2</sub>O ceases to come over (500°) so steam is admitted; (1) and (3) are returned to the absorbers. Dihydroxy phenols (II) should be removed before I in handling low-temp. and vertical-retort liquors. The liquor is brought to  $p_H$  5–6 by means of mineral acid to ppt. org. matter which would cause waste and to remove sulfides and carbonates. In some cases distn. is sufficient pretreatment; in others it is necessary to add CaOCl<sub>2</sub> and CaO. After decantation, C<sub>6</sub>H<sub>5</sub>O<sub>2</sub>Pb is pptd. at  $p_H$  8 (obtained by addn. of NH<sub>4</sub>OH) by a soln. contg. 46.05% PbCl<sub>2</sub>, 38.37% NaOAc, 14.8% H<sub>2</sub>O and 0.78% HNO<sub>3</sub> (d., 1.4). The Pb ppt. is treated with concd. HCl, filtered, steam distd. and evapd. to give crystals of II. A. S. CARTER

**Shipment and use of powdered Rhenish brown coal.** H. M. KASPER. *Arch. Wärmewirt.* 10, 1–8, 57–61 (1929).—In 1927 112,000 tons of powd. Rhenish brown coal were shipped; 91 cars are used in this service. This report gives details, with many illustrations and figures of results attained, as to cost of distribution, and the use of this coal in power plants, locomotives, reduction of metals, heating tempering and annealing. A bibliography of 46 items is added. ERNEST W. THIELE

**Rapid moisture determination in dry brown coal for briquet manufacture.**—ALFRED FABER. *Z. angew. Chem.* 42, 406–7 (1929).—The Deutsche Braunkohlen-Industrie-Verein and the Braunkohlen-Syndikaten offered prizes amounting to 6000 R. M. for the best methods of H<sub>2</sub>O detn. in brown coals contg. 5–25% H<sub>2</sub>O, using a sample of 20 g. (to avoid errors in sampling), requiring not more than 5 mins. to carry out, and checking the xylene distn. method within  $\pm 0.5\%$ . First prize was awarded the Frankfurter Forschungsinstitut für Getreidechemie G. m. b. H. for a method depending upon the measurement of the dielec. const. of the coal samples, simple elec. instruments being used; time needed, about one min. Second prize (Trauthwein) was won for a method based upon the measurement of H<sub>2</sub>O distd. from the coal placed in a special electrically heated app.; time required, 5–5.5 mins. Third prize (Kubierschky) was given for a method similar to the xylene distn. process, but amyl alc. or a mixt. of amyl alc. and paraffin oil was used; time required, 9–10 mins. Fourth prize (Müller) was given for a method employing 10 g. coal, shaken exactly 2 mins. with 40 cc. glacial AcOH, filtered, and 5 cc. of filtrate titrated, with phenolphthalein as indicator; time, 9 mins. The fifth prize-winning method called for 20 cc. glacial AcOH, a 2-min. shaking period, filtration through glass, distn. into a cond. cell, and measurement of the cond.; time, 8.5 mins. Rossiger and Becker proposed a method for the rise of temp. produced when 5 g. of sample is shaken with 50 cc. concd. H<sub>2</sub>SO<sub>4</sub> in a round-bottom flask, and comparison with curves obtained from coals of known H<sub>2</sub>O content. In all 57 methods were proposed, and of these 9 were investigated in detail. W. C. EBAUGH

**The nation's fuels.** I. Industrial ethyl alcohol and the synthesis of methanol. GEORGES KIMPFILIN. *Rev. gen. sci.* 39, 700–3 (1928). II. Benzene and gas. *Ibid.* 40, 177–82 (1929). III. Gas producers. *Ibid.* 211–5.—The economic situation of France with regard to fuels for internal-combustion engines is reviewed. A. S. C

**The new Basel Gas Works at Kleinhüningen.** K. MEIER. *Schweizerische Bauzeitg.* 93, No. 11, 135–8 (1929).—Features of gas works occupying area of 14 hectares, producing 300,000 cu. m. per day, with gas holders up to 50,000 cu. m. capacity, ammoniac plant, waste-products distillation plant, etc. E. I. S

**Standard pressure base for gas measurement.** F. E. HUFF. *Petroleum World Oil Age* 26, No. 3, 118 (1929).—The advantages of using the standard abs. unit, 14.73 lbs., as the base for all gas-vol. measurements instead of any of the 9 arbitrary base units now in use are pointed out. M. B. HART

**The new coking process at the Jena municipal gas works.** J. GULICH. *Gas. Wasserfach* 71, 1113–9 (1928).—Coal in vertical retorts was covered with a layer of 10–20 mm. coke at least 700 mm. thick, to prevent clogging of the upper coal surface, to increase the gas yield by cracking the tar and also to increase the rate of heat transfer through the charge. Various thicknesses and positions of the coke layer were tested and results reported. Steam was admitted after the seventh hr. instead of the tenth hr. as in usual operations, but only for the first half of each hr. An increased yield of GAN, DAVIS, carbons was secured, especially during the first part of the coking period. cf. C. A. 22, 2828. The gas yield was increased from the usual 17.9 to 13.5%. A coke yield gave in addn. to oil was obtained. The tar yield was decreased, and more coke was required made alk. with NaOH and condensed. The gas yield was increased from the usual 39 cu. m. of 490 B. t. u. bases (I) and neutral oils (II); th B. t. u. per cu. ft. R. W. R.

**Gas analysis.** P. RASSFELD. *Gas u. Wasserfach* 72, 344–7 (1929).—The gas analysis is to use phys. methods whenever possible, giving NH<sub>4</sub>Cl upon treatment with 1 gas analysis is to use phys. methods whenever possible, condensed and extd., giving carboxylic acids. A considerable improvement in methods for 9% was obtained. The compn. of the crude liquor obtained by substituting fractional combustion over

CuO for the explosion method. H and CO are burned quantitatively at 250–300°. CH<sub>4</sub> is not affected at this temp., but is burned quantitatively at 700–800° over CuO. Absorption of the CO<sub>2</sub> is required for complete combustion of either CO or CH<sub>4</sub>. A suitable app. and technic are given. The residue after combustion, commonly called "nitrogen," has been investigated by the interferometer, and found to consist of a mixt. of N and higher homologs of CH<sub>4</sub> (not burned quantitatively over CuO in the absence of O) as well as traces of benzene or other org. vapors.

R. W. RYAN

**A simple analysis of generator gases.** JAROSLAW DOLINSKI. *Przemysl Chem.* 11, 757–63(1927).—This is a graphical method. With the aid of a phase diagram and determinations of only CO<sub>2</sub> and N<sub>2</sub> such values as sp. gr., calorific value, etc., for a given generator gas can be read off directly and with sufficient accuracy. A. C. ZACHLIN

**The gas generator in the gas industry.** G. NEROT. *Science & ind.* 13, 153–60 (1929).—The diverse category of app. which has been successively employed for the firing of furnaces is indicated. A description is given of the most characteristic types of app.

FRANK V. JOHNSON, JR.

**Determination of the calorific value of gas.** HANS LÖFFLER. *Chem. Fabrik* 1929, 232–3; cf. *C. A.* 22, 1460.—Description of the Strache-Löffler "Caloriskop," with which a detn. may be made in about 2 mins. with an accuracy of about 0.3% over a range from 7000 to 13000 Cal.

J. H. MOORE

**Absorbing liquids for technical gas investigations.** OTTO WOLF AND ARTUR KRAUSE. *Tech. Hochschule, Darmstadt Arch. Warmewirt.* 10, 19–21(1929).—The rate of absorption of CO<sub>2</sub> by KOH solns. rises rapidly up to 4% by wt., then more slowly with a max. at 28%. The rate for NaOH is nearly the same as that for KOH up to 4%, beyond which the rate falls slowly. The most rapid rate of O<sub>2</sub> absorption with alk. pyrogallol is at 18% KOH, 15% pyrogallol, and 67% water, but there is a secondary max. at 10% KOH and 5% pyrogallol. No CO could be detected in the residual gases. The soln. recommended for CO is: 20 wt. % Cu<sub>2</sub>Cl<sub>2</sub>, 13.6% NH<sub>4</sub>Cl, 44.4% H<sub>2</sub>O, 22.0% NH<sub>3</sub> soln. of sp. gr. 0.96.

ERNEST W. THIELE

**Water-gas and producer-gas plant at Billingham Synthetic-Ammonia Works.** ANON. *Engineering* 127, 348–51, 362, 450–2, 508–10(1929).—For use in a modified Haber process there have been erected 12 water gas units capable of gasifying over 400 tons of coke in 24 hrs., and 4 mech. gas producers to supply N in amts. 1/3 as great as H from the water-gas sets. Complete descriptions and illustrations are given. The water-gas cycle consists of 5 stages, controlled automatically, viz., "blow" of 1 min., with a "blow purge" of 10 secs., the gases escaping to stack; and an "up-run" of 2.5 mins., a "down-run" of 1 min., and a "run purge" of a few seconds, the last named with air. Coke is fed continuously into the generators. Of special interest are the heat-utilizing and automatic-control devices employed.

W. C. EBAUGH

**Steam, flue gas, and blast-furnace gas as additions to the gas-producer air blast.** W. WISLICIENUS. *Arch. Warmewirt.* 9, 331–4(1928).—W. computes the exit temps., efficiencies, heating values of the gas produced, etc., for a theoretical producer gasifying pure C, using air diluted in the 3 ways, and undiluted.

ERNEST W. THIELE

**Ignition of combustible gas with three-part spark.** TORAHIKO TERADA, KIYOHIKO YUMOTO AND RYŌZŌ YAMAMOTO. *Inst. Phys. Chem. Research, Tokyo. Proc. Imp. Acad. (Tokyo)* 5, 125–6(1929); cf. *C. A.* 23, 2296.—When a jet of coal gas is directed very near the electrode surface (+) or (–), the ignition easily takes place, but the type of spark is mostly changed into the ordinary zigzag type, especially for (+). The frequency of ignition was, therefore, measured by the % of the cases of ignition relative to all the cases in which the sparks were decidedly of the 3-part type. The frequency thus defined, if plotted along the spark track, shows decided minima near the resp. junctions of (+) and (–) parts with the middle part. Along the middle part a max. (80%) is found at a point somewhat displaced toward the negative side from the middle. At the minima, the frequencies fall decidedly below 10%. When the gas jet is at the surface of (–) electrode it seems to approach 100%. At (+) electrode, the 3-part type becomes very rare, so that the frequency as above defined becomes indeterminate. With H<sub>2</sub> qual. similar phenomena were observed, though the effect of the jet upon the form of spark is much different.

C. J. WEST

**Improving the thermal balance of a boiler.** CH. VAN DER PUTTEN. *Sucr. Belge* 262(1929).—The advantages of flue-gas heaters for combustion air over economizers are reviewed.

F. CAMPS-CAMPINS

**Combustion mechanism in the Bunsen flame.** F. HABER. *Metallbörse* 18, 960–1 (1928).—The following processes occur in the hydrogen flame, (1) 2H<sub>2</sub>O = O<sub>2</sub> + 2H<sub>2</sub>; (2) 2H<sub>2</sub>O = 2OH + H<sub>2</sub>; these are linked in (3) 4OH = O<sub>2</sub> + 2H<sub>2</sub>O; (4) H + OH = H<sub>2</sub>O; (5) H + H = H<sub>2</sub>; (6) 2OH = H<sub>2</sub>O<sub>2</sub> + 41 kg. cal. From the heats of forma-

tion and from the disson. of water vapor it is concluded that  $H_2O_2$  is completely decomposed into OH in the flame so that the first product of the  $H_2$  combustion process is OH. The thermal data indicate that the combustion of H ought to be spontaneous. However, it is assumed that either the  $H_2$  or the  $O_2$  undergoes a chem. change necessitating heat absorption before it rapidly reacts with its partner. This "activation" cannot be the decompn. of elementary  $H_2$  into atoms, for this requires too much heat and could not occur rapidly enough near the lower explosion limits of flames. The following reactions occur on combustion of CO, (1)  $O_2 = O'_2$ ; (2)  $O'_2 + CO = CO_2 + O$ ; (3)  $O + CO = CO_2$ ; (4)  $CO + OH = CO_2 + H$ ; (5)  $H + H_2O = OH + H_2$  ( $O'_2$  is oxygen in an activated state due to absorption of 37 kg.-cal.). The hydrocarbon flame shows the spectrum of  $C_2$ , CH and OH. Carbon vapor is preponderantly monatomic from ordinary temp. to the b. p. of C. The reaction  $C_2 + OH = CO + CH$  is exothermal.

S. L. B. ETHERTON

**Determination of temperatures in combustion motors.** C. BONNIER. *Compt. rend.* 188, 957-9(1929).—The temp.  $T_1$  of the gas in a combustion motor on the compression stroke at the instant that the pressure is equal to 1 atm. can be calcd. from the formula  $v_2 = vT_1/273 + v_1(p_1/p_2)^{1/\gamma}$ , where  $v_2$  is the known vol. at  $T_1$ ,  $v$  is the vol. at  $273^\circ$ ,  $v_1$  is the vol. remaining after the exhaust stroke,  $p_1$  is the corresponding pressure and  $p_2$  is the pressure on the detonation stroke corresponding to the piston position at  $v_2$ .

A. S. CARTER

**Poisoning from auto exhaust gases.** H. KUNZ-KRAUSE. *Pharm. Zentralhalle* 70, 261-5(1929).—A discussion of the nature and toxicity of certain components of the exhaust gases of internal-combustion engines, their detoxication taken in comparison with the toxicology of illuminating gas.

W. O. E

**The cracking of coal tars.** G. EGLOFF. *Min. Congress J.* 15, 203-4, 217(1929).—Tar can be commercially converted into motor fuel by the cracking process. Its operation is described.

E. I. S

**The "e-phenols" of primary tar.** G. VAVON AND N. ZAHARIA. *Ann. combustibles liquides* 3, 541-51(1928).—See C. A. 23, 1247.

R. E. SCHAAD

**Skin lesions among tar workers.** HAROLD B. WOOD. *J. Cancer Research* 13, 54-9(1929).—Different types and composition of tars are discussed. Only tar obtained from the distn. of coal at high temps. contains a substance carcinogenic to certain lab animals. Workmen handling coal tar showed tar warts as a result, but no other effect. No irritant action on the human skin was found from low-temp. distillate tar or from petroleum tar.

H. G. WELLS

**Becker coke-oven plant for the Nunnery Colliery Co., Sheffield.** ANON. *Engineering* 127, 453-6(1929).—A modern lay-out of Becker coke ovens and auxiliary app is described. The products from the plant are (weekly) 2800 tons of coke, 50 tons  $(NH_4)_2SO_4$ , 36,000 gal. tar, 13,600 gal. crude  $C_6H_6$ , and about 27 million cu. ft. de-benzolized gas of 550 B. t. u. The ovens (25 in no.) have an av. width of 14 in., work on the regenerative principle, require 12 hrs., 50 mins. for carbonizing, have a capacity per oven of 12.2 tons or 22.4 tons per 24 hrs., and yield 7000 cu. ft. of surplus gas per ton of dry coal. Each oven is 40 ft. long and 12 ft., 6 in. high. Automatic reversal of flow through regenerators is effected every 20 mins.

W. C. EBAUGH

**Distinguishing marks and methods of detecting (allotropic) forms of carbon in coke.** G. AGDE AND FR. SCHIMMEL. *Feuerungstech.* 17, 97-100(1929).—A review with 19 references.

ERNEST W. THIELE

**Coke as fuel.** T. F. HURLEY. *Automobile Eng.* 19, 135-7(1929).—Description of some comparative tests with low-temperature coke and charcoal. Bench tests were made with a Tulloch-Reading producer with mixing valve which allows the engine to run on gasoline or suction gas, or both; a Dorman 4-J.O engine was used. Low-temp. coke may eventually prove a satisfactory fuel for heavy motor vehicles. Producers designed for use with charcoal as fuel require some modifications.

E. I. S.

**Dry quencher operation at Rochester, N. Y.** FREDERICK J. PFLUKE. *Ind. Eng. Chem.* 21, 457-61(1929).—The operating results of a dry coke-quencher installation after a two-year continuous operating period are reviewed. The benefits and objections to dry quenching are briefly summarized.

Liquid fuels. EUGENE A. PRUDHOMME (to Soc. internationale des procédés Prudhomme). U. S. 1,711,855, May 7. Hydrocarbon vapors such as products of low-temp. coal, lignite or peat distn. are subjected to a succession of catalytic stages which effect hydrogenation, dehydrogenation or splitting up into unsatd. hydrocarbons and satn. and polymerization. U. S. 1,711,856, relates to a generally similar process in which a suitably proportional quantity of a reducing gas such as water gas is added to the vaporized products undergoing treatment before entry into each catalyzer. An arrangement of app. is described in each of these pats.

Smokeless fuel. CHARLES É. BIRR. Fr. 651,181, Aug. 26, 1927. An agglomerated smokeless fuel contains, *e. g.*, coal dust 90, fuel oil 2, mazout 2, starchy matter 4, cellulose 2, CaCO<sub>3</sub> 1 and CaO 1%.

Carbonizing fuel. IMPERIAL CHEMICAL INDUSTRIES, LTD. Fr. 650,735, Mar. 10, 1928. Powd. fuel is preheated in an uncompressed state and on nearing the coking temp. is forced by pressure through a container where coking occurs. The coke takes the shape of the container which may contain a grid to divide up the coke into rods which are cut into blocks by a knife at the end of the container. Superheated steam may be passed in counterflow through the coke.

Apparatus for evolving and recovering volatiles from carbonaceous fuels and for agglomerating the solid residue. W. B. RULON. Brit. 299,611, Oct. 27, 1927. Structural features.

Hydrogenation. I. G. FARBERIND. A.-G. Fr. 650,975, Mar. 17, 1928. In the hydrogenation of coal, tars, etc., the oily constituents are removed from the residues by cautiously heating the residues, partly with the heat from the hydrogenation products. Steam may be introduced which allows working at a higher temp., and the residues are advanced by a screw. The final residues may be used for making active charcoal or as a powd. fuel.

Hydrogenation. I. G. FARBERIND. A.-G. Fr. 650,974, Mar. 17, 1928. In the hydrogenation of coal, mineral oils, etc., the substances entering and (or) leaving the reaction chamber form a heat envelope between the reaction chamber and the wall supporting the pressure.

Apparatus for destructive distillation or drying. KAROLINE DOBBELSTEIN NÉE BUSSMANN, ROLF DOBBELSTEIN, ALINITA DOBBELSTEIN, OTTO DOBBELSTEIN and IRMGARD DOBBELSTEIN. Ger. 475,048, Apr. 17, 1926. Addn. to 455,679. Improved

means are described for forcing the powd. initial material into the disk-like distn. or drying chambers forming a feature of the app. described in Ger. 455,679.

**Low-temperature destructive distillation apparatus.** KOHLENSCHIEDUNGS-GER. M. B. H. Ger. 475,283, Nov. 24, 1926. The app. is particularly designed for the distn. of lignite, and is of the kind comprising a shaft with adjustable partitions down which the lignite is moved.

**Distillation of coal.** COMPAGNIE DES MINES DE VICOIGNE, NOEUX ET DROCOURT. Fr. 651,445, Sep. 5, 1927. In low-temp. distn. of an agglomerated coal, the coal is heated slowly, *i. e.*, 2° per min. for poor coal,  $\frac{1}{10}^{\circ}$  for certain coking coals, during the phase where a change of phys. constitution is taking place. Thus, agglomerated coal contg. 8% tar made with a certain Pas-de-Calais gas coal is heated rapidly to 350°, then 0.2° per min. to 450°, and more quickly above, giving a good marketable product which shows no swelling.

**Distillation of coal.** LOW TEMPERATURE CARBONIZATION, LTD. Fr. 651,650, Mar. 23, 1928. A series of retorts are cast in one piece, and have a rectangular or oblong section, narrowing towards the top. Fr. 651,651 describes a distn. in 2 phases, water being caused to pass into the 2nd retort or into the discharge chamber into which the warm residue is discharged. Fr. 651,652 describes a 2-phase process in which gas is drawn off in the neighborhood of the junction between the upper and lower retort, and this gas is evacuated along with the gas formed and drawn off at the top of the upper retort.

**Distillation of coal or other solid carbonaceous materials.** HEINRICH KOPPERS. U. S. 1,712,082, May 7. Heat-storing bodies such as steel balls are heated separately from the material to be distd. and then brought into contact with the material to heat it and effect distn. of hydrocarbons. An arrangement of app. is described in which the heating bodies and material undergoing distn. may be agitated together in a rotating retort. U. S. 1,712,083 relates to app. for carrying out similar processes.

**Gasifying coal.** OTTO GROSS. Fr. 650,475, Mar. 6, 1928. See Brit. 289,080 (C. A. 23, 691).

**Agglomerating coal.** SOC. ANON. DES ENGRAIS ET NOIR ANIMAL. Fr. 651,462, Sep. 7, 1927. The paste obtained by the action of  $H_2SO_4$  on ligneous and cellulosic substances at a slightly raised temp. is used with or without the addn. of charcoal for agglomerating coal.

**Soluble products from coal.** I. G. FARBERIND. A.-G. Fr. 650,722, Mar. 10, 1928. The yield of products extd. from coal by solvents is increased by first heating the coal to 100–600° under pressures of 2–100 atm. Solvents such as  $C_6H_6$  or its derivs., hydrogenated  $C_{10}H_8$ , alcs., ketones, petroleum, mineral oils or tar oils may be used, and the products may be subjected to cracking or hydrogenation without sepn. from the solvent. Lignite contg. much water is excepted.

**Apparatus for drying and distilling lignite, peat, non-coking coal, etc.** HUBERT DEBAUCHE. U. S. 1,713,032, May 14. A vertical cylindrical retort chamber built from firebrick is surrounded by a heating chamber, and within the retort is positioned a concentric multi-conical ring device of different diams. such that an upper annular space of greater width is provided for drying the carbonaceous material and a lower annular space is provided for carbonizing the fuel. Various other structural details are described.

**Extraction of oils.** I. G. FARBERIND. A.-G. Fr. 651,150, Mar. 23, 1928. Oils of high b. p. are extd. from residues of mineral or tar oils or of the hydrogenation of coal, etc., by the introduction, at temps. above 300° and under reduced pressure, of gases or vapors which form liquids of low b. p. in the liquid state, preferably as a mist. Examples are given of the treatment of mineral oil and lignite hydrogenation residues with damp steam.

**Distillation of oils.** THE BARRETT CO. Fr. 651,127, Mar. 22, 1928. The gases from coke ovens or retorts are cooled and freed from tarry matter by spraying them with oils, which may be those obtained in the condensers of the carbonizing plant, or dirty oils which it is desired to distil and which are recovered by condensation. The process prevents hardening of pitch in the collector mains. Suitable app. is described.

**Distillation of crude benzene.** SOC. DES ÉTABLISSEMENTS BARBET. Fr. 650,138, Aug. 12, 1927. Crude benzene is sepd. into 4 fractions, benzene, toluene, xylene and solvent naphtha, the first 3 by continuous rectification under atm. pressure and the last by a discontinuous rectification under vacuum. An app. is described.

**Purifying gas.** H. KOPPERS A.-G. (to C. J. Hansen). Brit. 299,302, Oct. 22, 1927. Gas contg.  $NH_3$  and  $H_2S$  is scrubbed with a soln. contg. iron and oxy compds. of S and the liquor is regenerated by adding  $SO_2$  or a compd. such as  $NH_4HSO_4$ . The

gas may be further successively scrubbed with a bisulfite soln. and with a sulfite or thio-sulfate soln. and free  $\text{NH}_3$  may be added to the gas at the beginning of the operation if the gas is low in  $\text{NH}_3$ .

**Purifying gases.** THE GAS LIGHT & COKE CO. Fr. 651,605, Oct. 27, 1927. In treating gases contg. CO, such as coal gas, with adsorbent agents such as active charcoal for the removal of hydrocarbons, the adsorption is carried out in Cu-, or Zn-lined vessel to avoid the formation of Fe carbonyl which reduces the efficiency of the charcoal.

**Water gas.** CALEB DAVIES, JR. U. S. 1,712,983, May 14. The fuel bed of a water-gas generator is blasted with air supplied through a highly heated heat-transfer chamber, the blast gas is discharged to heat a second heat-transfer chamber and air is supplied for combustion; steam is then passed through the second heat-transfer chamber and to the fuel bed of the generator so that the ash of the latter is maintained at a temp. which will effect slagging; hot water gas is discharged from the generator through the first-mentioned heat-transfer chamber and the fuel bed is then blasted with air passed through the heat-transfer chamber and hot products are thence passed through fuel for the generator.

**Water gas.** H. NIELSEN and B. LAING. Brit. 299,485, May 28, 1927. Heat is first stored in a chamber contg. brickwork or the like and powdered carbonaceous material and steam are then passed through the chamber. Air may be admitted with the steam and CO present converted catalytically to  $\text{CO}_2$  in the presence of steam, the  $\text{CO}_2$  being then removed to obtain a mixt. of H and N suitable for  $\text{NH}_3$  synthesis.

**Carbureted water gas.** P. DVORKOVITZ. Brit. 299,482, April 27, 1927. See Can. 285,091 (C. A. 23, 960).

**Apparatus for generating water gas from powdered fuel.** J. PINTSCH A.-G. Brit. 299,421, Oct. 26, 1927. Hot water gas from the producer serves, in an assoc. drying and distg. app., to dry and distil the fuel while it is in circulation in the water gas, and steam generated while drying the fuel is used in the generator. Various structural details are described.

**Producing water gas and quenching coke.** J. PINTSCH A.-G. Brit. 299,315, Oct. 21, 1927. Coke is first subjected to a hot air blast and then passes downwardly (in an app. which is described) and is treated with quenching water which produces steam and the latter passes through the superposed body of coke and forms water gas. Cf. C. A. 23, 1741.

**Apparatus for the recovery of heat in water-gas plant.** FRANKFURTER GASGESELLSCHAFT and FRANZ REICHARD. Fr. 651,638, Mar. 19, 1928.

**Mixed coal gas and water gas.** FREDERICK D. MARSHALL. U. S. 1,713,189, May 14. Coal is fed under mech. pressure through a plurality of passages into a vertical carbonizing retort and is carbonized under mech. pressure to produce coal gas and coke. The coke is passed into a water-gas generator and blasted with air to produce blow gas and the latter is passed in heat-interchange with air; the blow gas and heated air are then mixed and are burned externally to heat the carbonizing retort. Alternately, steam is passed downwardly through the heated coke in the water-gas generator to form water gas; the water gas is cooled by heat exchange with water in a steam boiler and steam is thus generated for the water-gas production. The water gas and coal gas produced as described are mixed with each other. Various details of app. are described.

**Lighting gas.** DEMETRIO FUTACCHI. Fr. 650,961, Mar. 17, 1928. H for lighting gas is obtained by passing gases contg. CO and  $\text{H}_2$  such as industrial gas, and steam over Fe turnings or waste at a temp. of 650–750°, and eliminating  $\text{CO}_2$ . Gases obtained by cracking heavy oils may be added.

**Hydrocarbons and alcohol from natural gas.** HYLEMAN A. WEBSTER (one-half to Everet T. Schuler). U. S. 1,711,913, May 7. An app. is specified comprising 2 retorts, to one of which a portion of the gas is supplied while the other retort is heated by the other portion of the gas; connections are provided for supplying steam alternately to the retorts and for supplying air alternately with the steam supply, and a catalyzer chamber is connected to the retorts and supplied with gases from them.

**Gas producer.** FRIEDRICH A. G. D. VAN VLAARDINGER and JACOB VAN VLAARDINGER. Fr. 650,481, Mar. 6, 1928. A producer suitable for distg. inferior quality fuel, particularly waste wood, is described.

**Vertical gas-retort construction.** C. H. LANDER and J. F. SHAW. Brit. 299,201, Nov. 11, 1927. In a metal vertical retort for low-temp. carbonization of coal, the horizontal section has its opposite sides parallel and the retort is of such shape that the rate of increase of its cross-sectional depth (and if desired also its width) is greater toward the discharge end than near its upper end. Brit. 299,202 also relates to the construc-

tion of similar retorts, the lower end of the retort being connected with the duct leading to the coke extractor by a joint permitting relative motion between the retort and duct and the lower part of the retort being of such a cross-section that when expanded by heating it will not have a larger cross-section than that of the adjacent part of the discharge duct. Various other structural details are described.

**Exhaust motor gases.** DEUTSCHE GASGLÜHLICHT-AUßER-GESELLSCHAFT M. B. H. Fr. 650,786, Mar. 12, 1928. The exhaust gases from internal-combustion motors are passed over oxidation catalysts to convert them into  $\text{CO}_2$  and water.

**Distilling tar.** C. WESSERL. Brit. 299,290, July 24, 1928. The process for distg. tar and recovering naphthalene as described in Brit. 273,675 (C. A. 22, 2049) is modified by first heating the tar indirectly to  $180^\circ$  to drive off water and light oils, then discontinuing the original indirect heating while the naphthalene is distd. off with steam injected at a temp. of about  $215^\circ$ . The process may be carried out continuously by passing the tar from one vessel to another in which the 2 sep. stages of distn. are conducted.

**Dehydration and distillation of tar.** THE BARRETT CO. Fr. 650,770, Mar. 12, 1928. Tar is dehydrated by direct contact with the hot gases from coal-distn. retorts. The coal gases may be used at such a temp. that partial distn. of the tar takes place, the gases being passed through condensers to recover the vaporized oils which may be returned to the tar. Cf. C. A. 22, 4779.

**Apparatus for purifying tar used in gasometers.** KONRAD JAGSCHITZ and PAUL M. KUHN. Fr. 651,627, Mar. 9, 1928.

**Coke from lignite.** CHEMISCH-TECHNISCHE-GESELLSCHAFT M. B. H. Fr. 651,013, Mar. 28, 1927. Coke in pieces is obtained by drying lignite, mixing it intimately with emulsions of bituminous substances such as coal-tar pitch or asphalt, with or without sulfite cellulose pitch, placing the mixt. in thick layers and coking. The lignite treated with emulsions may be partly or wholly dried before coking.

**Horizontal coke ovens.** C. OTTO & CO. G. M. B. H. Fr. 651,644, Mar. 23, 1928

**Coke ovens and gas retorts.** ANTON WEINDEL. Fr. 651,114, Mar. 22, 1928  
Construction and arrangement of canals for the distn. products.

**Combined cooling and quenching apparatus for coke.** KOHLENSCHIEDUNGS-GEH. M. B. H. Ger. 475,282, Dec. 17, 1926.

## 22—PETROLEUM, LUBRICANTS, ASPHALT AND WOOD PRODUCTS

W. F. FARAGHER

**Lubricating oils.** J. TAUSS AND M. DREIFUSS. *Petroleum Z.* 24, 1383-1412 (1928).—The lubricating properties of various oils as shown by marginal angles of oils on metal surfaces, by the surface tension of oils and their temp. functions, and by viscosity measurements in small capillaries are studied. The detn. of marginal angles according to the method of Von Dallwitz has no significance in detg. the character of oil or the choice of the bearing metal. The surface-tension-temp. function of oils between  $20^\circ$  and  $100^\circ$  was detd. by the capillary method; in this temp. range it is almost linear. Mol. wt. of oils cannot be detd. from surface-tension measurements according to the equation of Eötvös-Ramsey-Shields but if the mol. wt. is known the value of  $K_s$  can be detd. and hence the crit. temp. and the b. p. of viscous oils. The ratio of surface tension to mol. wt. decreases with the dielec. const. of the oils. Viscosity detns. by means of capillary tubes were unsatisfactory because of friction in narrow capillaries and, therefore, the decrease in an oil layer subjected to a load between two highly polished metal surfaces of the same or different metals has been measured. Dielec. consts. of various oils are reported which, compared with the refractive index  $n_D$ , show that the value of a lubricating oil varies inversely with the value  $\sqrt{K} - n$  at the highest viscosity.

**Fundamental research program.** H. S. TAYLOR. *Oil & Gas J.* 27, No. 42, 120 (1929).—Review of the results so far obtained in the Am. Petroleum Inst. research projects.

**Midcontinent refining problems.** FRED PADGETT. Univ. Oklahoma. *Oil & Gas J.* 27, No. 42, 148, 248, 250(1929).—Some of the technical problems confronting the oil refiner are reviewed briefly.

**Developments in refining petroleum in 1928.** H. W. CAMP. *Refiner Natural Gasoline Mfr.* 8, No. 3, 66(1929); *Oil & Gas J.* 27, No. 40, 30, 106(1929).—Important developments during the year are the increased use of continuous-treating methods;

recovery of treating agents; better boiler-house practice; production of dry and superheated steam and feed-water treatment; installation of high-pressure boilers in connection with bleeder-type turbines which generate electricity at practically no added cost; use of water-cooled furnace walls; and the use of acid sludge as fuel. The general trend in liquid-phase cracking is toward larger units. The pipe still has been adapted to continuous vacuum distn. M. B. HART

Who laid the foundations of the petroleum industry in Poland? J. PFANHAUSER. *Przemysl Chem.* 13, 102-6(1929).—Rzaczynski in 1721 described the properties of petroleum from the foothills of the Carpathians. Other 18th-century references to petroleum in Poland are mentioned. Ignacy Lada Lukasiewicz constructed the first kerosene lamp in 1852 while engaged in his pioneer expts. on distg. petroleum. This date is a year before Silliman's similar independent expts. in the U. S. The paper is largely a bibliography of the work of Lukasiewicz, with portrait. A. C. ZACHLIN

Refining of petroleum distillates. A. E. DUNSTAN. Anglo-Persian Oil Co. *Oil & Gas J.* 27, No. 42, 169, 175(1929).—Soda washing eliminates  $H_2S$  from the oil but mercaptans are not removed completely. Distn. of the spent soda gives some of the mercaptans, but some are oxidized to disulfides by Na polysulfides. M. B. HART

High-pressure fractionation responsible for liquid petroleum gas. GEORGE REID. *Refiner Natural Gasoline Mfr.* 8, No. 2, 63-4(1929).—The Skelly Oil Co.'s high-pressure fractionation system is described briefly.  $C_4H_{10}$ -free gasoline, practically pure  $C_4H_{10}$ , and "Skelgas" (liquefied  $C_4H_{10}$ ) are produced. M. B. HART

Cracking light oils at low pressure. GUSTAV EGLOFF. *Oil & Gas J.* 27, No. 42, 151, 241(1929).—Light cracking stock of  $39.5^\circ$  A. P. I. and I. B. P.  $350^\circ$  F. from Pennsylvania crude oil when cracked at a pressure of 220 lbs./sq. in. produced over 65% of finished gasoline. Complete data on runs and products from a com. plant are given. M. B. HART

Washing heavy cracked naphthas with soap gives good color. D. F. GERSTENBERGER. *Natl. Petroleum News* 21, No. 8, 61, 64, 66(1929).—Pressure distillate is distd without steam to promote aging and to reduce the amt. of acid needed for treating. The treated distillate is rerun with fire and steam. The bad color of some heavy naphtha, caused mainly by the breaking down of certain S compds. during the final distn., can be improved by treating the distillate in the vapor phase with "Seafoam," a soap made by the Palmolive-Peet Co. It is claimed that the soap soln. remains flocculent in the gas oil; it is drained from the tank. M. B. HART

Survey of gravities of domestic crude oils. G. R. HOPKINS AND A. B. COONS. *Bur. of Mines, Circ.* 6114, 26 pp.(1929).—The av. gravity of the crude petroleum produced in the U. S. in 1927 was  $32.2^\circ$  A. P. I., sp. gr. 0.864, as compared with  $32.0^\circ$  A. P. I. for 1921. New Mexico crude oil had an av. gravity of  $48.5^\circ$ . The Casmalia field, Santa Barbara County, Calif., produced an oil of 6.8 gravity or 1.023 sp. gr. The straight-run gasoline in 1927 formed 24% of the total crude run. The weighted av. S content for 78 samples of crude oil analyzed was 1.16% as compared with 1.90% for West Texas. A Cat Canyon crude oil, Santa Barbara Co., Calif., contained 4.13% of S; an oil from Greybull field, Big Horn Co., Wyo., showed only 0.08%. Tables of data for crude oils by fields are given, which include gravities, yields, posted prices, and gasoline and S content. E. E. CRANDAL

Special processing of coking crude oils. G. W. CUPP, JR. *Refiner Natural Gasoline Mfr.* 8, No. 2, 59-63(1929).—General procedure in running crude oil to coke is described. M. B. HART

Comparison of Midcontinent crude oils. SIDNEY BORN. *Transcontinental Oil Co. Oil & Gas J.* 27, No. 44, 34, 139(1929).—A comparison of the cost of producing and refining crude oil from Pecos County, Texas and a typical 30-gravity Midcontinent crude oil indicates that the Texas field has an advantage because of its closeness to Gulf ports. The points of greatest difference in the crude oils are a larger kerosene yield, and a high content of lubricants of low cold test in the Texas crude oil. The gasoline from it has also a higher content of aromatic and naphthene compds. M. B. HART

Distillation of Crane County crude oil. J. W. NEWTON AND W. W. LEACH. *Magnolia Petroleum Co. Oil & Gas J.* 27, No. 42, 100(1929).—During the distn. of a regular charge of the crude (960 bbls.) contg. about 3 tons of S, approx.  $1/2$  comes off as  $H_2S$ . The S content of the heavy ends of the gasoline is high. The S contents of various cuts of gas and oil are tabulated. M. B. HART

Refining value of Hendricks crude oil. C. K. FRANCIS. *Oil & Gas J.* 27, No. 42, 147, 245-6(1929).—A complete workup of Hendricks crude oil with various methods of treatment and analysis of the products. The general properties of the oil are: gravity

30.4° A. P. I.; color, brownish green; odor,  $H_2S$ ; S, 1.518%; sediment, trace; pour, below 0° F.;  $H_2O$ , none. Products obtained on distn. with steam were: 25% of gasoline of 54.8° A. P. I., I. B. P. 116° F., and E. P. 436° F.; 5% of kerosene of 39.0° A. P. I., flash 156° F., fire 176° F., 15% of gas oil, 31.9° A. P. I., flash 120° F., fire 225° F.; 27% of lubricating oil distillate of 26.4° A. P. I., flash 100° F., fire 190° F.; 27% of fuel oil of 12.6° A. P. I., flash 410° F., fire 545° F. Treatment and analysis of products, including cracked gasoline and blended fuels, are given. M. B. HART

**Oil-field emulsions.** I. LESTER C. UREN. Univ. Calif. *Natl. Petroleum News* 21, No. 13, 51-2, 54, 56-7(1929).—The fundamental phys. and chem. nature of oil-water emulsions is discussed. Analyses of typical California oil-field emulsions are given showing gravity, emulsion, free and total water content. M. B. HART

**Treating emulsions without cost.** R. VAN A. MILLS. *Oil & Gas J.* 27, No. 49, 45, 150(1929).—Cut oil in the Tonkawa field is treated with the brine from the well at its natural temp. of about 90° F. The oil enters at the top of a sepg. tank into a flume made from gasoline drums welded together after removing the heads and rises from the bottom of the flume through the warm brine. Clean oil overflows from the tank. Excess brine is removed through a gooseneck overflow. M. B. HART

**Aromatizing shale oils by cracking.** N. WEIDERPASS. *Sitzb. Naturforsch. Ges. Univ. Tartu* 34, 143-53(1927).—An Estonian shale-oil distillate b. 200-300° was cracked in a tinned-iron tube at 600°, 700° and 750°. The cracked oils were fractionated. A pressure of 18 mm. was used for temps. above 150°. The benzene, toluene and xylene fractions were sepd. by distg. through a Hempel column contg. Pt-wire gauze. Benzene was detd. by nitrating the benzene fraction after treating with  $H_2SO_4$  (d. 1.84). The percentage of benzene was also calcd. from the gravities of benzene, the benzene fraction, and the nonaromatics present, by assuming the last to be 0.720. PhOH was detd. by heating the fraction b. 175-185° with  $BzCl$  under a reflux condenser. Naphthalene was sepd. from the 185-220° fraction by freezing; the percentage of anthracene in the 310-360° fraction was obtained in the same way. EMMA F. CRANDAL

**Measurement of the interfacial tension between mineral oils and aqueous solutions—influence of temperature and  $p_H$ .** H. WEISS AND E. VELLINGER. *Compt. rend.* 188, 901-3(1929). H. R. MOORE

**Measurement of the interfacial tension between mineral oils and aqueous solutions—influence of the degree of refining and degree of alterations of the oils.** H. WEISS AND E. VELLINGER. *Compt. rend.* 188, 1099-1101(1929).—Cf. preceding abstr. H. R. MOORE

**Distillation apparatus in use in natural gasoline manufacture.** J. E. KOBERNICK. *Oil & Gas J.* 27, No. 41, 132, 146(1929).—The history of the development of app. for distg. fat absorption oil is reviewed. M. B. HART

**Control in continuous distillation.** C. E. MASON. Foxboro Co. *Oil & Gas J.* 27, No. 42, 153, 154, 157(1929).—Flow controllers and liquid-level controllers are considered to be necessary to ensure uniform quality of vapor from towers. M. B. HART

**Treating pressure distillate.** W. R. HOUNSELL. *Oil & Gas J.* 27, No. 43, 31, 147-8(1929).—Pressure distillate after treatment with 7 lbs. of  $H_2SO_4$  per bbl. and removal of the acid sludge is treated with ammoniacal  $Cu(OH)_2$  soln., settled, and the sludge withdrawn. Gasoline produced by this method is claimed to be of uniform quality. M. B. HART

**Establish specifications for special grades of motor fuel.** C. E. KERN. *Oil & Gas J.* 27, No. 44, 34(1929).—Proposed specifications for U. S. Government motor gasoline and "Motor Fuel V" are given. M. B. HART

**N. Y. state specifications for gasoline.** ANON. *Oil & Gas J.* 27, No. 47, 148(1929).—Specifications effective June 1, 1929 are given. M. B. HART

**Summary analysis of gasoline.** A. MENUCCI. *Bole. informaciones Petroliferas (Buenos Aires)* 6, No. 53, 7-10, 12-14, 16-18, 20-22 and 23-6(1929).—A discussion of the Chavanne and Simon method as adopted by the war ministry of France for examn. of automotive fuels, and of the Egloff and Morrell method, rejected as unsuitable for aviation gasoline. A new analytical method is described. E. I. S.

**Rectification of gasoline fractions.** H. D. WILDE, BRIAN MEAD AND S. P. COLEMAN. *Oil & Gas J.* 27, No. 42, 102, 172(1929).—The air-equil. method of detg. vapor pressure is described and its application in refinery operations discussed. M. B. HART

**Treating gasoline at Columbian plant located at Lefors.** G. G. QUINN. Columbian Gasoline Corp. *Oil & Gas J.* 27, No. 44, 132, 139(1929).—The hypochlorite treating plant operated by the Columbian Gasoline Corp. at Lefors, Texas, is described. M. B. HART

**Continuous treating system.** G. REID. *Refiner Natural Gasoline Mfr.* 8, No. 3,

102(1929).—In the Cushing Refg. & Gasoline Co. plant gasoline and kerosene are sweetened by pumping a mixt. of the oil and a soln. of Ca hypochlorite through a pipe coil which discharges into settling tanks. The treating agent may be recirculated until it becomes spent.

M. B. HART

**Oxidation of paraffin hydrocarbons.** G. EGLOFF AND R. F. SCHAAD. *Oil & Gas J.* 27, No. 43, 156, 173-4(1929).—From the amts. of the various paraffin hydrocarbons in com. fuel gases, it is calcd. that  $2 \times 10^{13}$  cu. ft. of  $\text{CH}_4$ ,  $\text{C}_2\text{H}_6$ ,  $\text{C}_3\text{H}_8$  and  $\text{C}_4\text{H}_{10}$  are available for conversion into oxidation products such as alcs. It is estd. that 21 billion gallons of  $\text{CH}_3\text{OH}$ , 5 billion gallons of  $\text{C}_2\text{H}_5\text{OH}$ , 2.5 billion gallons of  $\text{C}_3\text{H}_7\text{OH}$  and 1.7 billion gallons of  $\text{C}_4\text{H}_9\text{OH}$  could be made from these gases. Research problems in this field are listed.

M. B. HART

**Mixture ratio in rating motor fuels.** JOHN M. CAMPBELL, WHEELER G. LOVELL AND T. A. BOYD. General Motors Corp. *Oil & Gas J.* 27, No. 42, 111, 161(1929); cf. *C. A.* 22, 4782.—In rating fuels as to knocking tendency it is important that the mixt. ratio be controlled as accurately as possible. The carburetor should be adjusted for each fuel to give the mixt. ratio that causes the max. degree of knocking. M. B. H.

**Knock ratings of pure hydrocarbons.** A. W. NASH AND DONALD A. HOWES. Univ. of Birmingham. *Nature* 123, 526-7(1929); cf. *C. A.* 23, 2561. Polemical with Birch and Stansfield (*C. A.* 23, 2813). N. and H. point out that their anti-knock values for trimethylethylene and for diamylene are based on volume percentages whereas B. and S. express theirs as weight percentages. Errors in measurement of anti-knock values arise from lack of attention to air-fuel ratios. Pentene-2 and trimethylethylene resemble cyclohexene in forming peroxides on exposure to air and light.

ARTHUR FLEISCHER

**Many advantages in centrifuge method of making bright stock.** J. T. YOST. *Oil & Gas J.* 27, No. 40, 156, 160, 162(1929).—At the Pure Oil Co. the Sharples process is used for the dewaxing of cylinder stock. A close-cut naphtha having an end-point of 380-400° F. is the diluent used. Advantages of this method over cold settling are a saving of naphtha and increased yield of bright stock of improved quality.

M. B. HART

**Liquid sulfur dioxide in refining.** ROBERT L. BRANDT. *Oil & Gas J.* 27, No. 42, 119, 167, 268, 270(1929).—The Edeleanu process as applied to lubricating oils, kerosene and engine distillate is described. Costs are given.

M. B. HART

**Test decolorizing value of clays.** C. F. BARB. Colorado School of Mines. *Oil & Gas J.* 27, No. 42, 116, 161, 163(1929).—The results of phys. and chem. tests on 21 samples of clays selected from a variety of sources are presented. The chief difference in the compn. of filtering and nonfiltering clays seems to be in the percentage of  $\text{Al}_2\text{O}_3$ , 15% being the max. compatible with efficient filtering. The efficiency for animal fats seems to depend on the CaO content. Acid-treated clays, however, appear to improve with decrease in alk. salts; hence a definite statement cannot be made. High kaolin content indicates a low decolorizing efficiency. Acid treatment may change a clay worthless as mined into a good decolorizer.

M. B. HART

**Determination of detonation ratings.** G. G. BROWN. Univ. of Mich. *Oil & Gas J.* 27, No. 41, 156, 158, 160, 162(1929).—The value of a motor fuel depends on its knock rating and volatility. The former can be detd. satisfactorily only in some kind of engine test, which should be checked by actual road tests. The methods used in testing fuels at the automotive lab. of the Univ. are described and results obtained with various fuels are shown in the form of graphs.

M. B. HART

**Single-flash units reduce costs and increase yields.** FOSTER WHEELER CORP. ENGINEERING DEPARTMENT. *Oil & Gas J.* 27, No. 42, 116, 164, 167(1929).—Typical installations are described briefly. The flexibility of the stills is shown by data from several methods of distg. a crude oil.

M. B. HART

**New inhibitor discovered for protective pipe coatings.** H. K. IHRIG. *Oil & Gas J.* 27, No. 42, 266(1929).—"Inhiburine," a new inhibitive primer recently acquired by Hill, Hubbell & Co., contains an inhibitor which is sol. in bitumens and in the solvent of the bituminous primer but insol. in  $\text{H}_2\text{O}$ . The inhibitor is a stable coal-tar product, basic in reaction.

M. B. HART

**Manufacture of lubricating greases by pressure method.** E. N. KLEMGARD. *Refiner Natural Gasoline Mfr.* 8, No. 3, 68(1929).—There are at least 4 grease plants in the U. S. now using the pressure method in preference to the open-kettle method. One of these plants has made approx. 30,000,000 lbs. of cup grease in the last 5 years by this method with entirely satisfactory results. The advantages of the process are (1) uniform batches; (2) loss of batch practically eliminated; (3) the process may be standardized readily so as to be handled by inexperienced operators; (4) cooking re-

quires at least 2 hrs. less time and there is no guesswork as to when sapon. is complete; and (5) one 5- or 6-bbl. soap kettle can produce sufficient base for 20 or 30 open-type grease mixers. A formula for making medium cup grease is given. M. B. HART

Progress in grease manufacture. RALPH R. MATTHEWS. *Battenfield Grease & Oil Co. Oil & Gas J.* 27, No. 42, 148, 246(1929).—Scientific lubrication calls for compounded greases prepd. for special uses. A new type of pressure-gun grease made from naphthenic acids and Al stearate is recommended. M. B. HART

The lubrication of air compressors. H. M. DAVID. *Mech. World* 85, 324-5 (1929). E. I. S.

Transformer insulating oils. W. E. WARNER. *Power House* 23, No. 5, 35(1929).—Causes and removal of asphaltic sludge are discussed. E. I. S.

Selecting transformer oil. H. HEYDEN. *Elektrizitätswirtschaft* 28, 14-9(1929). E. I. S.

The testing of transformer oils. K. TYPKE. *Elektrotech. u. Maschinenbau* 47, 357-62(1929). C. G. F.

Inspection and testing of transformer oil. O. S. HOCKADAY AND D. B. McDONALD. *Gen. Elec. Rev.* 32, 243-6(1929).—A detailed description of the methods of sampling and testing. Samples of oil in transformers of smaller size than 300 kva. are tested twice yearly; oil in larger transformers is tested quarterly. The oil-testing set is illustrated. W. H. BOYNTON

Reclaiming gasoline-engine oils. CHARLES VAN BRUNT. *Gen. Elec. Rev.* 32, 266-7(1929).—A machine has been marketed which uses concd. silicate of soda and a strong blast of air for evapg. the diluent from the running oil that flows in a thin film over corrugated electrically heated plates. The silicate corrects the acidity and removes all solid matter and other deleterious products of oxidation, forming a dense and heavy sludge, that settles rapidly and completely from the oil into a body of water. The water flows constantly, flushing the sludge, which is oil-free, into the drain. These arrangements make possible an automatic, continuous process. Many oils require an addn. reagent to promote the peculiar effect. Outstanding features of the machine, which is illustrated, are its automatic action and the negligible labor charge. W. H. B.

Fluidity and other properties of aviation engine oils. E. R. LEDEKER AND F. R. STALEY. *Texas Pacific Coal and Oil Co. J. Soc. Automotive Eng.* 24, 149-54(1929).—A general discussion of the fluidity or consistency of aviation-engine oils below their A. S. T. M. pour points and the significance of dewaxing paraffin-bearing oils. Small quantities of wax in lubricating oil change the pour test, the effect becoming more pronounced at low temps. A wax reduction of 0.20%, which changes the pour point by 2° F., lowers the temp. at which the oil changes from a plastic liquid to a plastic solid from +10 to -10° F. Comparative fluidities of various kinds of aero oils and corresponding oils from Coastal, California, Pennsylvania and Ranger crude oils are given. M. B. HART

What the oil man should know about airplane oils. C. M. LARSIN. *Petroleum Age* 23, No. 3, 26-7, 50(1929).—Tests conducted with various airplane lubricating oils indicate that fluidity has no definite relationship to viscosity times pour test. Furol viscosity and Greiner charts fail to indicate what an oil will do in actual service. M. B. HART

Standard engine for fuel tests. SUBCOMMITTEE ON DETONATION OF THE S.A.E. *J. Soc. Automotive Eng.* 24, 212-3(1929).—Exptl. knock-testing engine and regulations for testing are given as developed by the committee. M. B. HART

Cutting and quenching oils. C. H. HUDSON. *Mech. World* 85, 249-51; *J. Junior Inst. Eng.* 39, 215-23(1929).—A general article. E. J. C.

Comparative merits of oil and pulverized coal. EDWIN COLE. *Petroleum Times* 21, 235-6(1929).—A comparison of oil and pulverized coal for marine use shows that oil furnishes more B. t. u.'s per lb. than coal, gives higher boiler efficiencies, requires a smaller boiler-room staff, is fueled more readily, frees more storage space, and has been shown to be reliable. Although pulverized coal may supplant hand-fired coal in cargo steamers, it is not likely that it will replace oil in warships and fast liners. M. B. HART

Methods in refining roofing asphalts. W. W. PETERS. *Beacon Oil Co. Oil & Gas J.* 27, No. 42, 113, 163(1929).—Specifications of typical asphalts and general refining methods are given. M. B. HART

Pseudocumene derivatives from pyroligneous acid. BROR HOLMBERG. *Tek. Högskolan, Stockholm. Svensk Kem. Tid.* 40, 304-15(1928).—On redistg. the liquors from a local (Perstorp) pine-spruce charcoal plant, a cryst. mass formed in the condensers when the MeOH content had decreased 70%. The material was isolated by steam

distn. Colorless prisms, m.  $69^{\circ}$ , were obtained, which proved to be 5-pseudocumylacetone, a new chem. compd. Strong reduction changed this substance to  $\text{MeCH}_2\text{CH}_2\text{C}_6\text{H}_5\text{Me}$ , b.  $-226^{\circ}$ ,  $d_4^{20} = 0.887$ ,  $n_D^{20} = 1.5095$ ; mild reduction gave the corresponding secondary alc., m.  $74^{\circ}$ , as was checked by the Ph urethan, m.  $-115.5^{\circ}$ . A soln. of 5-pseudocumylacetone in glacial AcOH was added in small portions to a soln. of  $\text{Br}_2$  in AcOH cooled by ice water. A large excess of the  $\text{Br}$  soln. was added and the whole evapd. The substance formed was  $\text{MeCOCBr}_2\text{C}_6\text{H}_5\text{Br}_2\text{Me}$ . This  $\text{Br}$  deriv. was recrystd. from warm alc., giving needles almost as fine as hair, m.  $-116^{\circ}$ . Some durylic acid was also formed by oxidation with  $\text{Br}$  in  $\text{NaOH}$  soln. Treatment with alkali in alc. yielded unidentified resins. Grignard reagent gave  $\text{Me}_3\text{COHCH}_2\text{C}_6\text{H}_5\text{Me}$ , m.  $-45^{\circ}$ . This product was checked by synthesis. The yellowish oil from which the Perstorp crystals had been removed was dissolved in 0.5 N  $\text{NaOH}$  and then satd. with  $\text{CO}_2$ . Crystals, m.  $-95^{\circ}$ , which proved to be 6-pseudocumenol, not heretofore identified in wood distillates, were obtained.

A. R. ROSE

The formation and source of acetic acid and other volatile organic components of pyroligneous liquor. C. PADOVANI AND F. B. BURRAI. *Ann. chim. applicata* 19, 22(1929).—After reviewing previous work on the subject, the authors show that digesting wood pulp with weak alkalies gives a yield of AcOH (4–5%) almost equal to that obtained by pyrogenetic decompn. After this max. yield is obtained, no more is obtained except by the action under pressure of very strong alkali; the addnl. yield is obtained, evidently, by action on the cellulose of the plant. The AcOH is, therefore, present originally as a decomposable ester.

A. W. CONTIERI

The recovery of alkali extracts resulting from the industrial delignification of Tripoli woods. C. PADOVANI AND E. SALMOIRAGHI. *Ann. chim. applicata* 19, 23–45 (1928).—The exts. from the lixiviation with  $\text{Cl}_2$  of Tripoli wood when heated in an autoclave at temps. up to  $350^{\circ}$  at pressures above 200 atm. undergo a kind of "cracking," most of the org. matter charring. On decanting, clarified exts. are obtained that contain AcOH. From 100 parts of wood, the yields are:

	(from leaving plants)	coniferous	straw (i. e., bamboo, etc.)
AcOH	5.7	8.11	7
MeOH	1.8–2.4	1.6–2	1.4
$(\text{CH}_3)_2\text{O}$	0.3	0.3	—

A large variety of trees native to Tripoli were examd.

A. W. CONTIERI

The variation of viscosity with temperature. II. C. WALTHER. *Chem. Lab. f. Handel u. Ind.*, Berlin W 35. *Erdöl u. Teer* 4, 526–8(1928).—The formula proposed in Part I (C. A. 23, 316) was applied to several typical Russian and American oils. With the latter, the temp. factor ( $M$ ) was found to be the same (0.58) in every case but one. With the Russian oils, it was found to decrease (from 0.588 to 0.516) with increasing viscosity or sp. gr. Conclusions are drawn with reference to the valuation of the oil and the detn. of its source.

F. S. GRANGER

Fractional distillation analyses (PODBIELNIAK) 1. Skin lesions among tar workers (Wood) 21. Drying or destructive distillation apparatus (Ger. pat. 466,925) 1. Petroleum spirit. WM. M. KNOWLING (Michael Kostevitch, inventor). Fr. 651,641, Mar. 23, 1928. Petroleum spirit is purified by passing it through glaucol in the cold, the spirit may also be passed through active charcoal and active  $\text{SiO}_2$  gel. All these may be metallized with Cu, Ni, Pt, etc., in a finely divided state. Cf. C. A. 23, 1259.

Refining crude petroleum oils. ARTHUR LACHMAN (to Richfield Oil Co. of Calif.). U. S. 1,712,960, May 14. The oil is treated with  $\text{H}_2\text{SO}_4$  at a temp. slightly above atm. temp. and decanted from the resulting acid sludge, and is then subjected to a treatment at a higher temp. (suitably about  $170^{\circ}$ ) with  $\text{H}_3\text{PO}_4$  and again decanted from acid sludge formed; and the remaining acid in the oil is then neutralized (suitably with  $\text{NaOH}$ ) and the neutralizing agent is removed by washing with water.

**Cracking hydrocarbon oils.** JOSEPH F. DONNELLY. U. S. 1,712,789, May 14. A mass of relatively heavy oil is heated to a cracking temp. under sufficient pressure to prevent vaporization (suitably in a pipe coil) and the heated oil is discharged, before the cracking reaction reaches the condition where free C would be formed, into a zone of lower pressure and the cracking reaction is checked in the lower pressure zone, before it reaches the stage of free C formation, by introduction of cooler hydrocarbon oil. An arrangement of app. is described.

**Cracking hydrocarbon oils.** ROBERT E. WILSON (to Standard Oil Co. of Ind.). U. S. 1,712,187, May 7. Heavy oil such as a heavy distillate oil is subjected to distn. under 4-6 atm. pressure and at a conversion temp. and the distn. is continued until substantial conversion of the oil is effected and the unvaporized oil reaches an asphaltene content not exceeding 0.4%; unvaporized oil is removed while at conversion temp. and forced through a heated confined passage in which it is heated to 425° or higher and is discharged into a conversion chamber in which no substantial reduction in temp. of the oil is permitted; vapors and unvaporized oil are separately withdrawn from the conversion chamber. An app. is described.

**Cracking hydrocarbon oils.** HERMANN WOLF (to Carburul A.-G.). U. S. 1,711,869, May 7. Oil such as a "middle oil" is forced through a tortuous path, *e. g.*, a pipe coil, under pressure, in heat-interchange relation with a body of washing oil and thence through a further tortuous path in which it is heated to a cracking temp.; the pressure on the cracked product is then reduced and its velocity of flow thus accelerated and the expanded and rapidly flowing material is introduced into the body of washing oil, heating the latter and cooling the cracked products below the temp. at which after-reactions would take place; fresh washing oil is aspirated into the body of washing oil by the action of the flow of cracked products; vapors are dephlegmated and recovered, and products of higher b. p. are returned to the process. An app. is described.

**Use of a hypochlorite in cracking hydrocarbon oils.** HENRY BLUMENBERG, JR. U. S. 1,713,252, May 14. A metal hypochlorite such as Al, Zn, Na, K, Mg, Fe or Cu in dry form is added to a mineral oil such as crude or topped oils or distillates and the material is then heated to a cracking temp. to obtain products of lower b. p.

**Refining hydrocarbon oils.** HARRY K. IHRIG (to Associated Oil Co.). U. S. 1,712,619, May 14. Vapors of hydrocarbon material such as a Calif. oil distillate are brought into intimate contact with a heated mixt. of hydrated lime 1 and crude Fe oxide 3 parts, in order to remove corrosive impurities.

**Refining hydrocarbon oils.** JENÖ TAUSS. Ger. 475,277, Dec. 1, 1923. The hot oil or oil vapor is treated with very small amts. of O in order to accelerate the polymerization of the resin-forming constituents, the polymerization products being then removed. Other means of accelerating the polymerization may be additionally applied, *e. g.*, a glow discharge, irradiation or addn. of small amts. of acids or alkalies.

**Apparatus for distilling hydrocarbon oils.** ALFRED SCHWARZ. U. S. 1,713,149, May 14. U-shaped imperforated tubes extend from the top downwardly into a still and are provided with connections for supply of hot gases for heating the body of oil under distn. Various structural features are described.

**Distilling hydrocarbon oils.** DAVID G. BRANDT (to Heat Treating Co.). U. S. 1,713,254, May 14. Oil such as crude petroleum is passed upwardly through a series of zones of increasing temp. (in an app. which is described) and inert gas is passed upwardly through the oil; the oil and gas passing from the uppermost of these zones are further heated and unvaporized liquid from this latter heating stage is passed downwardly through the first-mentioned heating zones, while gas and vapors from such heating stage are passed upwardly through the heating zones; a portion of the vapors is condensed in each of the heating zones and the condensates are separately passed down through the cooler zones. U. S. 1,713,255 and U. S. 1,713,256 relate to similar processes and app. for use in carrying out the process.

**Retort for destructive distillation.** OTTO HELLMANN. Ger. 470,490, May 1, 1927. Addn. to 467,845 (C. A. 23, 1249). Structural improvements are described in destructive distn. retorts of the kind comprising an enclosed annular moving platform which carries the material to be distd.

**Cracking and hydrogenating oils.** PETROLEUM PROCESS CO. Brit. 209,347, June 13, 1927. Oils are passed, after heating, in counter current to a flow of heated gas such as steam, the mixed gases are reheated in a sep. chamber and finally passed upward through a stream of crude oil. Various details of app. and procedure are described.

**Cracking mineral oils.** WILLIAM G. LEAMON. Fr. 651,015, Mar. 19, 1928. Vapors from mineral oils are heated to a temp. somewhat above that desired for cracking, but

travelling at such a speed that little cracking takes place, and are led into a chamber contg. contact substances such as amorphous and colloidal forms of  $\text{SiO}_2$ , pumice stone, etc., in which cracking takes place at a temp. not above  $600^\circ$ . The vapors are freed from undesirable high b. p. constituents before being heated. An app. is described.

**Distillation of mineral oils.** THE PURE OIL CO. Fr. 650,343, Feb. 1, 1928. Oils are drawn through a heated tubular distn. vessel and the vacuum at the point of outlet extends toward the entry, at least to the point where "cracking" would take place under ordinary pressure.

**Separating water and solids from oil.** JOHN C. DEACON (to Standard Oil Co. of Calif.). U. S. 1,713,117, May 14. Oil contaminated with water and solids is continuously discharged upwardly through a body of water on the surface of which a scum is formed so that the oil passes through the scum and into a zone above it. Solids are added to the scum by the contaminated oil under treatment and other solids absorb water and settle to the bottom of the body of water from the scum; water is withdrawn from beneath the scum as it accumulates, and the oil which has filtered upwardly through the scum is continuously withdrawn. An app. is described.

**Filter for lubricating oil of internal-combustion engines.** R. P. F. LIDDELL (to Motor Improvements, Inc.). Brit. 299,434, Oct. 26, 1927. Structural features.

**Hydrogenating carbonaceous material.** MAX HOFSSÄSS. U. S. 1,711,499, May 7. Carbonaceous material such as Mexican crude oil, coal tar or oil sand is heated under pressure with H in the presence of hydride of anthracene and its homologs to a temp. (suitably about  $500^\circ$ ) at which the H in the hydride becomes unstable, in order to produce light liquid motor fuels.

**Separating oils from solid substances.** I. G. FARBENIND. A.-G. Fr. 650,573, Mar. 8, 1928. Oils, particularly those obtained as residues of "cracking" or hydrogenating operations, are sepd. from solid substances contained in them by mixing them, preferably with heat, with a liquid in which the oil is not sol. and the surface tension of which is such that the adhesion between the oils and the solids is decreased, after which the sepn. can be effected in any way. Water, to which wetting or emulsifying agents, such as sulfonic acids or Turkey red oil, and salts such as  $\text{CaCl}_2$  are added, may be used.

**Mineral wax.** A. RIEBECK'SCHE MONTANWERKE A.-G. Fr. 650,421, Mar. 5, 1928. Wax is deresinified and then extd. in the presence of decolorizing powder. Solvents used are mono- and poly-hydric alcs., e. g.,  $\text{AcOEt}$  or glycol monomethyl ether or ketones, e. g., butanone. Examples are given.

**Purifying paraffin.** WERSCHEN-WEISSENFELSER BRAUNKOHLEN-A.G. Ger. 475,313, Aug. 28, 1926. Paraffin is purified and its fastness to light is improved by treating it with decolorizing agents and radiations of short wave length together or in turn. O may be supplied during the irradiation.

**Rectifying and refining benzine.** GALICYJSKIE TOWARZYSTWO NAFTOWE "GALICJA" Sp. Akc. and HUGO BURSTIN. Ger. 475,227, Apr. 3, 1924. The benzine is vaporized and the vapor is led through a series of adsorbers contg., e. g., active charcoal and maintained at successively decreasing temps. Different fractions are adsorbed in the different adsorbers and are recovered therefrom in known manner.

**Chlorinating benzine.** INTERNATIONAL FIREPROOF PRODUCTS CORP. Fr. 650,738, Mar. 10, 1928. Benzine is chlorinated by 1st treating it to remove heavy oils and then bringing it into contact with Cl in the presence of a catalyst such as  $\text{AlCl}_3$  or  $\text{FeCl}_3$ .  $\text{C}_6\text{H}_5\text{Cl}$  is given as representing the gasoline and  $\text{C}_6\text{H}_5\text{Cl}_2$  the chlorinated compd.

**Viscous oils.** I. G. FARBENIND. A.-G. Fr. 650,799, Mar. 13, 1928. Viscous oils suitable as lubricants are obtained by acting on tars or mineral oils or their fractions b. beyond  $150^\circ$  with lower olefins such as  $\text{C}_2\text{H}_4$ ,  $\text{C}_3\text{H}_6$  and  $\text{C}_4\text{H}_8$  with heat and in the presence of condensing agents such as  $\text{AlCl}_3$ ,  $\text{ZnCl}_2$  and  $\text{Fe}_2\text{Cl}_6$ . The action of the condensing agents is increased by the addn. of salts such as a chloride of Hg or U.

**Treatment of bituminous sands.** KARL A. CLARK (to The Governors of the University of Alberta). Can. 289,058, Apr. 23, 1929. A process of sepg. bitumen from sand, silt or clay consists in mixing the compd. with a reagent (as soaps, silicate of soda, alkali and alk. salts), introducing the mixt. to a large body of hot water in small amts at a time with agitation from below the surface of the water, thereby sepg. the bitumen, adding an electrolyte to the wash to prevent coalescence of the sepd. bitumen with the sand, silt or clay and effecting flocculation of the reagent with the sand, silt or clay and recovering the bitumen from the surface of the wash water.

**Separating hydrocarbon polymers from crude alcohol mixtures.** SYLVAN R. MERLEY (to Doherty Research Co.). U. S. 1,713,346, May 14. In order to sep. hydrocarbon polymers from alc.-acid mixts. and alkyl sulfate mixts. such as may be produced from cracked petroleum products, the mixt. is dild. with water and the polymers are

absorbed from the dil. mixt. by a purified water-insol. straight-chain hydrocarbon material and the latter and assoc. polymer are removed before the mixt. is distd.

**Apparatus for recovery of gasoline from natural gas or similar mixtures.** HAROLD B. BERNARD (to Sinclair Oil and Gas Co.). U. S. 1,713,323, May 14. Various structural details of an absorption, distn. and dephlegmation system are described.

## 23—CELLULOSE AND PAPER

CARLETON E. CURRAN

**Future possibilities in the utilization of cellulose.** CHARLES H. HERTY. *J. Chem. Education* 6, 829-45(1929). E. H.

**Lignin and cellulose.** IX. Cellulose. KARL FREUDENBERG. Univ. Heidelberg *Ber.* 62B, 383-6(1929); cf. *C. A.* 23, 276.—Hess, after abandoning the view that cellulose is made up of monoglucosan units held together by forces which cannot be described according to the rules of the old doctrine of valence, now holds to a cellobiosan unit, his strongest argument being that cautious acetolysis of cellulose gives nearly quantitatively a hexaacetylbian. \*F. has repeated his expts. with K. Friedrich and found that the prepn. pptd. with MeOH has a varying Ac content (generally corresponding to that of a hexaacetylbian, to be sure). When, in order to remove the org. solvent, the prepn. is pptd. from Me<sub>2</sub>CO with much H<sub>2</sub>O and carefully dried, it regularly contains about 1% more (45.8%) Ac than the calcd. value for an acetylbian. The substance is therefore not a biosan but a polysaccharide with an av. chain length of 10-16 members. H. has already acknowledged that his "biosan" reduces Fehling soln to about the same extent as 1/8 its wt. of glucose, a fact confirmed by F. and F.; and since cellobiose has, as might be expected, not only 1/2 but more than 2/3 the reducing power of glucose, a polysaccharide of 10-16 glucoses might well have 1/8 the reducing power of glucose. After the glucosan, the biosan too must therefore be abandoned as the unit of cellulose. Lignin, like cellulose, is built up of primary valence chains

C. A. R.

**Hydrophilic properties of cellulose fibers after strengthening.** L. MEUNIER AND R. GUYOT. *Compt. rend.* 188, 506-8(1929).—The optimum conditions for viscose strengthening are 12 hour soaking in an aq. HCHO soln. (concn. greater than 5%), with a  $p_H$  between 1.6 and 1.2, preferably obtained from H<sub>3</sub>PO<sub>4</sub>. By an increasing degree of strengthening, the % swelling in pure H<sub>2</sub>O, the elongation at the rupture point, the absorption of substantive dyes or tannins, and the hydrometric water decrease, while the resistance toward alkalies and the tensile strength increase. The mechanism of strengthening is regarded as follows: (1) The influence of acids causes a partial transformation of cellulose into hydrocellulose, whereby the number of OH groups is increased (2) Evaporation concentrates the acid to a point where it becomes an active catalyst for the formation of methylenic derivs. (3) Two OH groups belonging to different chains react with HCHO. (4) The action of HCHO does not remain confined to the surface but penetrates deeply.

ALBERT L. HENNE

**Changes in nitrocellulose when exposed to light.** V. COFMAN AND H. B. DEVORE. *Nature* 123, 87(1929).—The observation by Rayleigh (*C. A.* 23, 3081) that celluloid contg. malachite green (I) becomes red when exposed to sunlight is explained by the fact that N oxides liberated from the nitrocellulose (II) convert I to a red coloring material. The wave length most effective (per quantum absorbed) in causing acid decompn. of II is about  $\lambda = 3100$  A. U., which does not correspond to the greatest absorption power of II.

FREDERICK C. HAIN

**New English patents relative to the viscose artificial silk industry.** WILHELM A. DYES. *Kunststoffe* 19, 30-4(1929).—A detailed résumé of the English patents issued in 1925 and 1926 which deal with the viscose artificial silk industry. In each instance the no. of the patent with a summary thereof is given.

B. HAMILTON

**The difficulty of mass production of homogeneous hydroacetylcellulose of better viscosity for acetate silk.** WILHELM A. DYES. *Kunststoffe* 18, 272-4(1928).—A résumé of the history of the manuf. and properties of cellite, and an exposition of the economic situation, with especial reference to the competition and the financial results thereof among the various firms engaged in acetate silk manuf.

B. HAMILTON

**Development tendencies in the acetate silk industry.** RICHARD FLINT. *Kunststoffe* 18, 275-9(1928).—An exposition of the economic phases of the acetate silk industry, with the inclusion of the interrelations existing among the firms engaged in the manuf. of acetate silk.

B. HAMILTON

**Carbohydrate changes in the course of sulfite cellulose cooking.** ERIK HÄGG-LUND and TORSTEN JOHNSON. Wood-chem. Inst., Abo. *Svensk Kem. Tid.* 41, 55-9 (1929); cf. *C. A.* 23, 2569.—In German. In a wood digestion run giving a cellulose yield of 49.7% the glucose equiv. of the liquors by direct reduction was 12% of the wood dry wt., which increased 3% by acid hydrolysis. This liquor was treated successively with  $\alpha$ -naphthylamine, norite and charcoal, then digested with chalk, again clarified, concd. and pptd. with alc., giving Ca salts at 8.3 g. per 100 g. wood. The Ca salts repptd. contained 9.6% Ca, 9.3% calcd. for  $\text{Ca}(\text{C}_6\text{H}_{11}\text{O}_7)_2$ . The presence of some pentose is assumed as the cause of the high Ca percentage. The Ca was quantitatively removed as oxalate and the filtrate clarified and concd., set aside 6 weeks for mannonic acid lactone to crystallize. No crystals formed. Phenylhydrazide crystallizes; m. 215°,  $(\alpha)_D^{20} = -10^\circ$ , N 9.52%. Brucine salt, m. 204°,  $(\alpha)_D^{20}$  27.4°. The Bertrand xylonic acid reaction gave characteristic  $\text{CdO}_2\text{R}\cdot\text{CdBr}_2$  crystals. Mannonic and xylonic acids have been identified in sulfite cellulose liquors. A. R. ROSE

**Generation of steam and power in sulfite cellulose factories.** L. MALM. *Ing. Vetenskaps Akad.* (Stockholm), No. 91, 57 pp. (1928). E. I. S.

**Problems of the forest products investigation.** H. WISLICENUS. *Z. angew. Chem.* 41, 1312-6 and 1345-51 (1928).—An address dealing with reforestation and wood-treatment technic. ALBERT L. HENNE

**Coöperation of the university with industry with special reference to pulp and paper.** H. K. BENSON. *J. Chem. Education* 6, 846-51 (1929). E. H.

**Bergmann turbines for paper and pulp industry.** H. FIELITZ. *Bergmann Mitteilungen* 7, No. 1, 10-4 (1929). E. I. S.

**Causes and prevention of deterioration in book materials.** ROBT. P. WALTON. *Bull. New York Public Library* 1929, 39 pp.—A compilation of abstracts. E. J. C.

Cellulose structure and direct dyeing (MEYER) 25.

GREIFFENHAGEN, ERICH: **Kunstseide. Vom Rohstoff bis zum Fertigfabrikat.** Berlin: L. Schottlaender & Co. 115 pp. Linen, M. 4.

HÖSSLE, FRIEDRICH VON, KORN, MOSEL, FRIEDRICH, OFFERMANN, E. and WALTER, LUDWIG, E.: **Technik und Praxis der Papierfabrikation. Band I. Roh-, Halb- u. Ganzstoffe d. Papierfabrikation. Tl. 1. Die Geschichte des Papiers, die Roh- und Halbstoffe der Papierfabrikation mit Ausnahme des Holzzellstoffes.** Berlin: O. Elsner 276 pp. M. 26.

PFÄU, JOHANNES: **Musterbuch der deutschen Papier-Erzeugung, 1928.** Biberach Riss: Güntter-Staib. 536 pp. Linen, M. 18.50.

**Alkali cellulose.** JEAN LAMASSIAUDE. Fr. 643,902, April 15, 1927. The ripening chamber is composed of a series of parallel isothermal tunnels the dimensions of which are reduced to that necessary to allow the wagons contg. the material to pass. Fr. 643,903 describes an app. for making alkali cellulose in which wood pulp in rolls is passed through the necessary baths, the soda being circulated inversely.

**Cellulose.** ERNEST C. H. VALET. Fr. 650,194, Feb. 29, 1928. Cellulose is sepd. from sugar-cane bagasse by treating the bagasse under pressure with a soln. of quick lime, running off the soln. and treating with NaOH soln. contg. KOH and finally adding  $\text{Na}_2\text{SO}_3$ . A final treatment with a weak soap soln. may be given. Cf. *C. A.* 23, 512.

**Preparing cellulose for acetylation.** I. G. FARBERIND. A.-G. Brit. 299,512, July 28, 1927. Cellulose in the form of paper sheets is preliminarily treated with glacial HOAc and may then be rolled up and fed continuously into an acetylating bath.

**Cellulose esters of organic acids.** HARRY LEB. GRAY (to Eastman Kodak Co.). U. S. 1,711,940, May 7. In processes such as that of treating cellulosic material with an acetylating liquid, the mixed materials are subjected to a vacuum to remove entrapped air preliminary to the esterifying reaction. U. S. 1,711,941 specifies a process in which cellulosic material to be esterified is mixed *in vacuo* with an inert volatile org. liquid vehicle such as  $\text{CHCl}_3$  or ether having dissolved in it the acylating agent, e. g.,  $\text{Ac}_2\text{O}$ , for the reaction and also carrying a catalyst such as  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{PO}_4$ , evapg. the volatile vehicle *in vacuo* and then breaking the vacuum and effecting esterification.

**Stabilizing cellulose acetates, etc.** I. G. FARBERIND. A.-G. Brit. 299,326, Oct. 22, 1927. Unstable cellulose acetates and other acylcelluloses are rendered stable by treatment with a hydrolytically acting agent such as dil. aq. or alc.  $\text{H}_2\text{SO}_4$  at atm. pressure and at a temp. not exceeding 100°.

**Flexible sheets of cellulose acetate composition.** RUDOLF ROLAND (to Roland Fire-

proof Celluloid Corp). U. S. 1,713,482, May 14. Sheets or films suitable for automobile curtain windows are formed of a compn. comprising acetyl cellulose 25, alc. 25, PhCl 10,  $C_2H_5Cl$  10, benzyl benzoate 10, triacetine 10 and dichlorohydrin 10 parts.

**Cellulose xanthogenate.** I. G. FARBENIND. A.-G. Fr. 651,060, Mar. 20, 1928. Impurities are eliminated from cellulose xanthogenate by  $CH_3OH$  to which water is added in such an amt. that the solvent power for the impurities is increased and swelling of the xanthogenate is avoided. The purification is carried out as rapidly as possible at a low temp., and the solvent is eliminated by pressing, all other drying being avoided.

**Threads, films, filaments, etc., from cellulose derivatives.** ALFRED LANDUCCI (to Du Pont-Pathe Film Mfg. Corp.). U. S. 1,713,289, May 14. A cellulose deriv such as nitrocellulose or cellulose acetate is dissolved in a suitable org. solvent and formed into the desired shape; coagulation is effected in an aq. bath to obtain a more or less opaque product, which is then rendered transparent by a hot air drying. Cf. C. A. 22, 1237.

**Desulfurization of viscose products.** I. G. FARBENIND. A.-G. Fr. 650,882, Mar. 15, 1928. The residual solns. coming from the purification of cellulose xanthogenate are used as solvent for the S pptd. on viscose articles. The solns. may be concd or dried and then taken up with solvents. The solns. may be used with other known desulfurizing agents. Cf. C. A. 23, 1750.

**Artificial silk.** I. G. FARBENIND. A.-G. Fr. 650,513, Mar. 6, 1928. The total output of a spinning machine spinning fine threads is maintained by providing at each spinning point 2 nozzles separately supplied with soln. The bundles of threads are kept sep., being led over double thread guides and wound on sep. spools.

**Artificial silk.** I. G. FARBENIND. A.-G. Fr. 650,862, Mar. 14, 1928. A silk of small total titer (*e. g.* 120 deniers and below) is obtained in "pot" spinning by choosing the diameter of the centrifuge so that the centrifugal force is sufficiently great to use spinning pots of diameter greater than the usual 160 mm., the speed of rotation being appropriate to the desired twisting.

**Artificial silk.** I. G. FARBENIND. A.-G. Fr. 651,006, Mar. 19, 1928. Threads, ribbons, etc., of viscose silk having a finely notched surface, are obtained by adding traces (not more than 0.1%) of a Zn salt, preferably  $ZnSO_4$ , to the pptg. bath.

**Artificial silk.** ERNEST C. H. VALET and OTTO FUNK. Fr. 651,491, Mar. 19, 1928. Cellulose produced from sugar-cane bagasse is used as starting material for the solns. for making artificial silk. The cellulose may be obtained as described in Fr 620,897.

**Apparatus for spinning artificial silk.** THOMAS W. HOLT. Fr. 650,595, Mar. 8, 1928. Construction and mounting of the spinning box or "pot" are described.

**Valve construction for nozzles for spinning artificial silk filaments from solutions.** BRITISH CELANESE, LTD., and J. BOWER. Brit. 299,405, July 26, 1927.

**Adhesive for fabrics, fibers, paper, etc.** ANNELESE RASCH, JOHANNES RASCH and IRENE RASCH. Ger. 475,038, July 25, 1920. Sulfite cellulose lye with its initial content of bases or after addn. of bases is evapd. to a sirup of sp. gr. 1.30-1.35.

**Chemical wood pulp.** DONALD B. BRADNER (to Champion Coated Paper Co) U. S. 1,711,584, May 7. Raw cellulosic material such as wood is digested in a cooking liquor contg.  $Na_2SO_3$ , forming sulfite pulp and waste sulfite liquor; the sulfite pulp is digested in an alk. cooking liquor contg. Na sulfide to form a pulp with a high content of  $\alpha$ -cellulose and waste alk. liquor; raw cellulosic material is digested with the waste alk. liquor to form a sulfate pulp and waste sulfate liquor.

**Wood pulp.** HOWARD F. WEISS (to Bauer Bros. Co.). U. S. 1,711,706, May 7. After satn. with water, the satd. material, in the presence of water, is subjected to the rolling and crushing action of 2 oppositely and concentrically revolving disks under pressure to sep. the fibers.

**Apparatus for pulping and beating paper stock.** WALTER WERNER (to Noble & Wood Machine Co.). U. S. 1,712,598-9, May 14. Structural features.

**Apparatus for making paper.** ROBERT E. ARGY. U. S. 1,712,374-5, May 7.

**Paper-making apparatus.** B. A. MALKIN. Brit. 299,236, Jan. 16, 1928. Structural features.

**Paper-making apparatus.** WILLIAM E. SHEEHAN. U. S. 1,712,587, May 14. A web carrier is used in the form of an endless belt of non-woven pounded felt such as may be produced by fulling an endless belt of carded wool.

**Paper for stencil sheets.** S. HORII. Brit. 299,520, July 29, 1927. Japanese stencil paper is made by subjecting the bast tissue to the wet beating process until the degree of wetness reaches 40 to 60 beating units by the Schoper-Riegler beating

tester. The paper may be coated with a compn. comprising waxes, gelatin or cellulose esters together with tempering agents. Cf. C. A. 23, 1229.

**Pattern effects on waxed paper.** ELSMORE D. LAKE. U. S. 1,711,953, May 7. A paper sheet is treated with a hot wax which normally renders the sheet transparent; certain areas of the sheet are cooled and other areas are subjected to pressure at the moment of cooling. An arrangement of app. is described.

**Glassine paper.** CHARLES E. SWETT (to U. S. Envelope Co.). U. S. 1,712,178, May 7. One surface of glassine paper is treated to reduce glare (suitably by aq.  $\text{CaCl}_2$  soln.) and the other surface is treated to increase transparency, e. g., by use of tannic acid and terpin hydrate.

**Glossing paper.** SIEBENHIRTNER CHEM. INDUSTRIE-WERK G. M. B. H. Fr. 651,273, Mar. 23, 1928. A glossy or satin surface is obtained on paper by adding saponified stearin and salts of heavy metals to the crude paper pulp. In an example, stearin saponifd. with  $\text{NaOH}$  or  $\text{KOH}$ , and  $\text{ZnSO}_4$  with sufficient  $\text{K}_2\text{SiO}_3$  or  $\text{Na}_2\text{SiO}_3$  to give the necessary consistency are used.

## 24—EXPLOSIVES AND EXPLOSIONS

CHARLES E. MUNROE

**Thermodynamic consideration of explosive reactions.** ALBERT SCHMIDT. Z. ges. Schiess- u. Sprengstoffw. 24, 41-6, 90-3(1929).—Methods are given for calcg. for a given explosive its heat of explosion, compn. and vol. of gases of explosion at that temp., and the explosion pressure, when the heat of formation and stoichiometric compn. of the explosive are known. The methods described are particularly applicable to explosives having a deficiency of O. The calcd. heat of explosion is somewhat lower than that detd. in the calorimetric bomb. Nitroglycerin, nitrocellulose and TNT are taken as examples for calcn.

C. G. STORM

**Experiments with explosive gas mixtures.** PAUL H. PRAUSNITZ. Oesterr. Chem.-Ztg 32, 63-4(1929).—Glass filters were used as a means of preventing the propagation of explosions in gaseous mixts. Wire gauze is liable to burn through and permit explosions whereas glass filters are not subject to this hazard. Filters with pore diam. about 0.1 mm. were safe with coal gas-air mixts., less efficient with H-air mixts., and not at all effective with H-O mixt. Tubes and filters of quartz were somewhat better than those of glass, and are recommended for use in expts. upon the combustion of gaseous mixts., as valves to prevent the spread of the burning gases.

W. C. E.

**Typical accident hazards caused by inflammable gas mixtures.** C. C. CUSTER. Nat. Engr. 33, No. 1, (pp.) 13-6(1929).

E. I. S.

**Explosibility of atmospheres behind stoppings.** H. F. COWARD. Colliery Guardian 138, 1139-42(1929).—A stopping is a wall built across old workings in a mine to improve the airway or confine gas which is being evolved. The results of analyses of stopping atms. are given and a table has been prepd. giving the relative explosibility of all mixts. of  $\text{CH}_4$  with O and N. By analysis the components of the stopping atms. may be detected and detd. If  $\text{CH}_4$  is the only inflammable component the menace from the stopping mixt. alone, or in admixt. with air, may be read off from the table. If other inflammable components are present the relative explosibility may be found from calcns. as shown in the article.

CHARLES E. MUNROE

**The mechanism of the stabilization of powders containing nitroglycerin by means of diethyldiphenylurea.** H. LÉCORCHÉ AND P. L. JOVINET. Compt. rend. 187, 1147-8 (1928).—The mechanism of the stabilization is based upon the fact that any nitrous acid present is absorbed by diethyldiphenylurea to form ethylphenylnitrosamine. Presence of the latter compd. may be detected by testing with  $\alpha$ -naphthylamine-HCl.

L. B. MILLER

**Flame speeds and their calculation.** W. PAYMAN AND R. V. WHEELER. Fuel in Science and Practice 8, 4-9, 91-8, 104-14, 153-62, 204-19(1929).—P. and W. have deduced the "law of flame speeds" by which, with fair accuracy, the speed of flame in mixts. of air with several flammable gases may be calcd., provided that the speed of flame, under the same conditions, in mixts. of air with each gas singly is known. The observations upon which this law is based are summarized and existing data concerning the speed of flame are analyzed to show the extent to which the law is obeyed. Thirty-four figures and 50 tables are included.

D. A. REYNOLDS

**The normal flame speed of nitrogen-rich gases (producer gases, blast-furnace gas).** H. PASSAUG. Tech. Hochschule, Wien. Feuerungstech. 17, 7-8, 15-21,

28-31(1929).—In most cases, the speed was detd. by passing air and the gas, at accurately known rates, into a burner of known diam., and noting the area of the inner cone of the Bunsen flame (not sepd. from the outer). Where no stable flame could be formed in this way, it was formed in a vertical glass tube, the upward velocity of the gas-air mixt. being known, and the downward velocity of the flame being noted. The 2 methods agreed well. Explosive limits for upward and downward propagation were detd. in a vertical tube with spark in the middle. The *viscosity* of the mixts. was detd. in a Schilling sp. gr. app., the orifice being replaced by a capillary. Seventeen mixts. contg. 36-71%  $N_2$  were studied throughout the explosive range. Some were made in a small producer, some by mixing the pure gases. The max. speed observed was 91 cm./sec. for a mixt. of 41.0% CO, 20.4%  $H_2$  and 38.6%  $N_2$ . Speeds as low as 5 cm./sec were observed. The effect of the various constituents was not different from that noted with richer gases.

ERNEST W. THIELE

**Flame speed of hydrogen sulfide.** D. S. CHAMBERLIN AND D. R. CLARKE. *Lehigh Univ. Pub.* 3, No. 3, 5pp.(1929).—App. and method for detg. flame speed of  $H_2S$  in air by horizontal flame propagation are described. Flame records were made by a photographic method, gas being inflamed in 2.5-cm. glass tube, open at one end and 1 m. long. Max. flame speed was found to be 49.5 cm. per sec. on burning 10.8%  $H_2S$ .

E. I. S.

**The development of the match industry.** KARL DOPF. *Z. ges. Schiess- u. Sprengstoffw.* 24, 23-4(1929).—Historical and statistical.

C. G. STORM

RAABYE, C. Artilleri I. Sprængstoffer. Til Brug ved Undervisningen Specialklassens vaabentechniske Kursus og Arterillerikursus. Copenhagen: Haerens Officersskole 188 pp.

RYBA, GUSTAV: Handbuch des Grubenrettungswesens. Band I. Brände und Grubenexplosionen. Die Ursachen, d. Verhüttg. sowie d. Bekämpfung. dieser Ereignisse und ihrer Folgen. 302 pp. M. 20; Linen, M. 24.

SOHLMAN, RAGNAR AND SCHUCK, HENRIK: Nobel. Dynamite and Peace. Translated by Brian and Beatrix Lunn. New York: Cosmopolitan Book Corp. 353 pp \$5. Reviewed in *Ind. Eng. Chem.* 21, 611(1929).

Explosions of lacquer drying ovens (ANON.) 26. Ignition of combustible gas with 3-part spark (TERADA, *et al*) 21. The optical chronograph [for measuring velocity of detonation of explosions] (RUMPF) 1.

**Explosive.** J. THIECKE and H. HERZOG (to Minimax A.-G. and Deutsche Pyrotechnische Fabriken A.-G.). Brit. 299,396, Oct. 25, 1927.  $NH_4NO_3$  and blood charcoal (preferably in the proportions of 85 and 15, resp.) are mixed in a state of fine division to produce a self-combustible compn. suitable for the generation of heat, N gas or compressed gases for various purposes. Wood charcoal may be added.

**Explosives.** A. SEGAY. Brit. 299,462, Oct. 27, 1927. In forming explosives contg.  $NH_4NO_3$ , NaCl or KCl and trinitronaphthalene, a large proportion in trinitronaphthalene is used corresponding to the quantity of O in the mixt. and nitroglycerin or  $KClO_4$ , or both, also may be added; the nitroglycerin may be gelatinized or an absorbent such as sawdust may be added. Trinitrotoluene may be used instead of a portion of the trinitronaphthalene; *e. g.*, an explosive may be prepd. from  $NH_4NO_3$  59, NaCl 18, trinitronaphthalene 8, trinitrotoluene 5 and  $KClO_4$  10%. Cf. *C. A.* 23, 2036.

**Explosives.** EDMUND VON HERZ. Ger. 474,173, Oct. 6, 1927. The trinitrate of methyltrimethylolmethane,  $CH_3C(CH_2OH)_3$ , is used as an explosive or propellant. It is prepd. by condensing  $CH_2O$  with  $EtCHO$  in the presence of  $Ca(OH)_2$  and treating the product with  $HNO_3$  or nitrating acid. It is a viscous oil which remains liquid at  $-15^\circ$ , is more stable than nitroglycerin, and can be worked up into powd. or gelatinous products in the same way as nitroglycerin.

**Nitrocellulose smokeless powder.** ALAN S. HAWKESWORTH. U. S. 1,713,505, May 14. Mononitrotoluene is used for simultaneously drying, dissolving and stabilizing the nitrocellulose.

**Nitroglycerin nitroglycol, etc.** DYNAMIT-A. G. VORM. A. NOBEL & Co. (to A. Schmid and J. Meissner). Brit. 299,384, Oct. 25, 1927. A modification of the procedure for sepg. explosives of this character from residual acids resulting from their manuf. is described, generally similar to the process specified in Brit. 284,701 (*C. A.* 22, 4821).

**Detonating firework composition.** WILLIAM F. GEHRIG (to Essex Specialty Co.). U. S. 1,712,555, May 14. A non-hygroscopic compn. which gives successive detonations when ignited comprises a S-P compd. such as P sesquisulfide together with an oxidizing agent such as  $\text{KClO}_3$  and  $\text{MnO}_2$  and an inorg. binder formed of  $\text{MgO}$  and an alum, e. g., Cr K alum.

## 25—DYES AND TEXTILE CHEMISTRY

L. A. OLNEY

**Advances in the realm of colors.** Z. PULAWSKI. Warsaw Polytech. *Przemysl Chem.* 13, 27–30, 149–53(1929).—Principally statistics on vat dyes, indigo and anthraquinone.

**Interesting sources of natural dyestuffs.** C. D. MELL. *Textile Colorist* 51, 329–32(1929); cf. C. A. 23, 2828.—A possible substitute for brazilwood is the tang tree from Borneo, known botanically as *Koompassia excelsa*. It is a very large tree of the bean family (Leguminosae) and therefore related also the logwood and certain other dye-yielding trees. Elderberry bushes as a source of dyes are discussed. Birch trees are valued more or less highly in many parts of the world as a source of tannin and dye.

**Testing dyestuffs for fastness.** NOEL D. WHITE. *Cotton* 93, 572–7(1929); cf. C. A. 23, 2574.—The testing of hosiery dyestuffs for fastness to crocking, milling and cross-dyeing are discussed from a practical standpoint.

**Testing, mixing and applying dyestuffs.** NOEL D. WHITE. *Cotton* 93, 203–5, 220(1928).—The first of a second series of practical articles on hosiery dyeing. Cf. C. A. 23, 709.

**Para red and its application.** J. STEPHEN HEUTHWAITE. *Textile Colorist* 51, 300–4(1929).—Paranitraniline red is a satisfactory substitute for Turkey red. It is fast to washing with soap and soda in hot water, perspiration and mineral acids, chemicking for bleaching purposes, and light and atm. influence. It is adversely affected by long boiling in alk. dye, boiling with dil. soln. of  $\text{H}_2\text{SO}_4$  or  $\text{NaHSO}_4$ , steaming under pressure, and solns. of Cu salts. Its application is described.

**2,4-Diaminodiphenylamine as an ursol dye.** P. P. KARPUGHIN. *Ukrainskii Khim Zhur.* 3, Tech. pt., 229–31(1928).—K. recommends 2,4-diaminodiphenylamine (I) for dyeing fur and leather. It is prepd. from 2,4-dinitrodiphenylamine (II) obtained by heating at  $75^\circ$  and stirring 1 mol. of  $\text{C}_6\text{H}_3\text{Cl}(\text{NO}_2)_2$  with 2 mols. of  $\text{PhNH}_2$  in presence of  $\text{H}_2\text{O}$ , expelling the excess of  $\text{PhNH}_2$  and filtering off the crystals of II, yield 100%. II is reduced to I with Fe and HCl, neutralized with  $\text{Na}_2\text{CO}_3$ , and after all Fe is settled, I is extd. with boiling  $\text{H}_2\text{O}$ , light brown needles. Russian muskrat skin, most difficult to dye, was degreased, then treated for 90 mins. at  $35^\circ$  with 200 cc. of liquor contg. 0.3 g. of I, 0.3 g. of AcOH and 10 cc. of 2.5% soln. of  $\text{H}_2\text{O}_2$ , for black dyeing. More dil. solus. with less  $\text{H}_2\text{O}_2$  give original yellowish brown dyeings (imitation of monkey fur). The skins mordanted with Cr salts give a black color with brown shading; Cu mordant gives deep black shades. I can also be used with a brush or a spray requiring several applications of treble strength. Chrome leather and unmordanted leather are colored in similar shades.  $\text{NaClO}_3$  can be used instead of perhydrol in equiv. amts. with addn. of traces of  $\text{VCl}_3$ . The skins dyed black without a mordant show a fastness to light of 2, dyed black with Cr mordant, 4; black with Cu mordant, 4.5; brown with Cr mordant, 2.

**The Donnan membrane equilibrium.** ALBERT P. SACHS. *Textile Colorist* 51, 225–9, 304–7(1929).—Such an equil. is shown to underlie the dyeing process.

**Cellulose structure and direct dyeing.** KURT H. MEYER. *The Melliand* 1, 76–9(1929); *Melliand Textilber.* 9, 573–5(1928).—Differences in affinity of the various com. cellulose fibers toward direct dyestuffs are explainable by x-ray data on the internal structure of the fibers, and shape and dimensions of the dye mol.

**The preparation, bleaching and dyeing of jute.** FRED. GROVE-PALMER. *Textile Colorist* 51, 322–6(1929).—General. Methods are described.

**Dyeing celanese drapery cloths with SRA colors.** R. G. DORT. *The Melliand* 1, 102–3(1929).—Dyeing recipes are given. The effects are quite fast.

**Obtaining good results in the one-bath process of hosiery dyeing.** L. J. MCGINTY. Wiscasset Mills, Albemarle, N. C. *Textile World* 75, 3307–9(1929).—Practical.

RUBY K. WORNER

**Salvaging hats by redyeing them.** GEORGE RICH. *Textile Colorist* 51, 307-(1929).—Methods are described. RUBY K. WORNER

**Thickeners for (textile) printing.** R. HALLER. *The Melliand* 1, 80-1(1929).—See C. A. 23, 2038. E. R. CLARK

**Printing with basic colors with emetic in one dye.** WACLAW KACZKOWSKI AND A. SMONBERG. Warsaw Polytech. *Przemysl Chem.* 13, 89-92(1929).—After proper purification glycerotannate gives with emetic a light yellow ppt., which can be dried at room temp., and produces correct colors. Addn. of a small quantity of oxidizing agent, and the use of various wetting agents, improve the brightness of the prints. Their fastness is normal, except that in laundering some are slightly weaker, and in tests on ironing somewhat better. A glycerol ester of antimonous acid, clear sirup of pale cream color,  $b_{30}$  180° was prepd. by treating 0.05 mol.  $Sb_2O_3$  with 0.2 mol. glycerol redistd. at low pressure, and heating the mixt. up to 210° for 2 hrs. A turbulent reaction with evolution of water vapor takes place at 200-5°. The ester is decompd. by water at room temp. with evolution of antimonous acid. A. C. ZACHLIN

**Coloring small glass beads and Christmas tree ornaments with aniline dyes.** WILHELM HANNICH. *Chem.-Ztg.* 53, 265-6(1929).— $H_2O$ -sol. aniline dyes are treated with  $H_2O$  and a colloid, such as gum arabic, gum tragacanth, albumin, gelatin, etc., placed in rotating drums, and thus deposited upon the glass objects to be colored. Freedom from Ca is a necessary condition to success in operating with many dyes. W. C. EBAUGH

**Use of direct illumination in microscopic examination of textiles.** ALOIS HERZOG. *The Melliand* 1, 2-7(1929); *Melliand Textilber.* 9, 832-5(1928); cf. C. A. 22, 4825 — The examn. of textiles by transmitted light is unnatural and wherever possible illumination from above should be preferred. Several low-power microscopes are available which are vastly superior to pick glasses for casual work. A no. of illuminating devices afford means for examg. textiles conveniently up to 150x. The uses of Lieberkuhn's mirror, the vertical illuminator and the Busch condenser are described and the effects obtained are illustrated. The German article contains some practical information about the *microscopy of paper*. The subject is extended by E. WYCHGRAM, *Melliand Textilber.* 10, 197-9(1929). E. R. CLARK

**The fiber plants of the Belgian Congo.** J. H. H. ROSS. *Faserforschung* 7, 180-94 (1929).—Cotton production is increasing and the quality is satisfactory. Kapok occurs natively. The flax produced is of inferior quality. *Raphia* is successfully cultivated. There is considerable local utilization of the fibers of *Boehmeria*; *Urena lobata*, *Triumfetta cordifolia*, *Cephalonema polyandrum*, *Sida rhombifolia* (Queensland hemp, denji fiber), *Hibiscus cannabinus* (African jute), konge-konge fiber, etc. Sisal production is being specially encouraged. E. R. CLARK

**Posidonia fiber.** A. HERZOG. *Faserforschung* 7, 199-201(1929).—*Posidonia* fiber is naturally retted from the sea-plant, *Posidonia australis*, found in the waters off southern Australia. The fiber is rather more lignified than jute and is not suited to fine enough division to make other than quite coarse yarns. The tensile strength is low. E. R. CLARK

**Cultivation of jute.** FR. BONSACK. *Faserforschung* 7, 133-76(1929).—The successful cultivation of jute demands an av. temp. above 24° for a period of 5 months, with av. monthly rainfalls increasing from 2 cm. to 75-100 cm. during the growing season. In north-eastern India, the desired climate is found together with low labor and transport costs, and it is quite unlikely that a profitable jute cultivation industry can be established elsewhere. E. R. CLARK

**Disease-resistant La Plata flax.** ALBERT BOERGER. *Faserforschung* 7, 177-89 (1929).—Increasing restrictions on the possibility of migration of flax culture in the Argentine, and efforts at the development of industries using flax straw, have made the study of wilt-resistant strains attractive. Several such have been developed commercially. E. R. CLARK

**Stains on piece goods.** L. L. LLOYD. *Wool Record* 35, 873-5(1929).—A lecture. The cause and removal of various stains occurring during the mfg. process are discussed. RUBY K. WORNER

**pH Control in the silk industry.** CHAS. E. MULLIN. *The Melliand* 1, 70-5(1929).—Control of pH is useful in almost all wet treatments of silk. E. R. CLARK

**Artificial silk soaking liquids.** S. R. TROTMAN. *Dyer, Calico Printer* 61, 48-9, 80(1929).—The use of "artificial silk soaking liquid" solves most of the difficulties of selecting a lubricant for rayon prior to knitting. Since these liquids contain no  $H_2O$ , there is no reduction of the tensile strength of the fiber. If properly prepd., no difficulties should arise in scouring or dyeing. The liquids consist of an acid soap dissolved

in a suitable org. solvent. The soap may be derived from an ordinary or a sulfonated oil; the solvent is generally a petroleum fraction, b. between 160° and 250°. Methods are described for detg. the nature and approx. compn. of these liquids, the flash point and the wetting power.

RUBY K. WORNER

**A qualitative test for degraded artificial silk.** O. S. RHODES. *J. Textile Inst.* 20, T55-6(1929).—A modification of Nessler's soln. for testing for oxycellulose is prepd. by dissolving 100 g. HgI<sub>2</sub> and 80 g. KI in 500 cc. H<sub>2</sub>O and adding 5 l. of 3 N NaOH soln. The mixt. is filtered through glass wool after standing overnight. Test samples are boiled (after removal of starch and other foreign matter) for 1 min. in the soln., rinsed with warm 1% KI soln., and finally washed with cold H<sub>2</sub>O. The presence of oxycellulose is indicated by a dark stain on a white background. With this treatment cuprammonium silk is not stained; viscose silk becomes light gray; undesulfurized viscose silk turns orange, then orange brown.

J. E. SNYDER

**Wool washing.** H. W. FAWCETT. *Wool Record* 35, 661-3, 667, 733-5, 739, 807 11, 881-3(1929).—Lecture and discussion. The Duhamel system of wool scouring by means of suint is described in detail. Its advantages over the usual soap scouring methods are pointed out.

RUBY K. WORNER

**Extraneous objects in cotton goods.** C. MARTINI. *The Melliand* 1, 40-6(1929).—See *C. A.* 23, 1274.

E. R. CLARK

**Control, computation, faults and tests in warp mercerizing.** JOHN H. SKINKLE. Lowell Textile Inst. *Textile World* 75, 3313, 3339(1929).—Common mercerization faults are too little luster, uneven dyeing, tender yarn, and harshness. Causes and remedies are suggested. Tests are described for detecting mercerization, detg. the strength of the caustic used, testing for oxycellulose or hydrocellulose, and testing for unneutralized acid in the yarn.

RUBY K. WORNER

**Soaps, solvents and detergents.** VERNON D. FREEDLAND. *Wool Record* 35, 1017-9, 1027(1929).—The selection of scouring reagents is discussed for raw wool and for wool yarn and piece goods.

RUBY K. WORNER

**Dyes.** BRITISH DYESTUFFS CORP., LTD. Fr. 648,158, Feb. 3, 1928. The vat dyestuffs prepd. according to Brit. 29,352 (1910) by treating dibenzoyl-4,4' (or 4,5')-diamino-1,1'-dianthrimides with H<sub>2</sub>SO<sub>4</sub> are treated with oxidizing agents, such as NaOCl and Na perborate, or Na persulfate. The agents may be added to the reaction mixt. or to the isolated dye.

**Dyes.** I. G. FARBERNIND. A.-G. Brit. 299,511, July 28, 1927. Sulfuretted dyes dyeing cotton orange and yellow shades in a Na sulfide bath are made by heating benzidine and S with 2- or 3-nitro- or amino-4-acetylitoluidine.

**Azo dyes.** J. R. GRIGY, A.-G. Ger. 473,526, Aug. 7, 1927. Strongly basic azo dyes are prepd. from mono- or poly-azo dyes contg. one or more primary or secondary amino groups, by treating them successively with chloroacetyl chloride and tertiary or secondary aromatic bases or di- or tri-alkylamines of the aliphatic series. Thus, a diazo soln. of  $\alpha$ -naphthylamine is neutralized with AcONa and added to a soln. of *N*-pyridylacetyl-2,7-aminonaphthol in water, and crystd. AcONa. The dye produced colors cotton a fast blue-red. Other examples are given. A table of dyes prepd. in this way, and their colors in various dye baths, are given. Cf. C. A. 23, 2833.

**Azo dyes.** BRITISH DYE STUFFS CORP., LTD. Fr. 651,585, Mar. 23, 1928. See Brit. 294,284, C. A. 23, 2041.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 650,312, Mar. 2, 1928. Azo dyes which are insol. in water are obtained by coupling a 2,3-hydroxynaphthoarylamine with a 4-aminodiphenylamine substituted in one or both rings by one or more alkyl or alkoxy or both groups, or by a halogen combined with one or more alkyl or alkoxy groups. A list of components and the colors obtained is given.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 650,688, Mar. 9, 1928. Azo dyes are prepd. by coupling 4,4'-diaminodiphenyl-3,3'-dicarboxylic acid (I) or its derivs. in any order with an aryl-naphthylaminesulfonic acid or one of its derivs., and with an azo component which contains sulfonic, carboxylic or other groups which increase the soly in water, such as hydroxyl, amino or ketomethylene. In an example (I) is diazotized and coupled with 8-hydroxy-1-phenylaminonaphthalene-4-sulfonic acid in alk. medium in the presence of pyridine. The mixt. is heated to about 40°, salted out and dried, giving a black powder which dyes cotton blue; this becomes faster and more green by a final treatment with Cu salts. The dye derived from (I), 5-hydroxy-2-phenyl-naphthylamine-7-sulfonic acid and 1-hydroxynaphthalene-5-sulfonic acid dyes cotton reddish violet, and the dye from (I), 8-hydroxy-1-phenylaminonaphthalene-4-sulfonic acid and sulfoacetacet-*o*-anilide dyes cotton grayish blue.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 650,778, Mar. 12, 1928. Diazo compds are coupled with components which have fatty acid radicals contg. arylhydroxy groups attached to the N atoms, or such radicals are introduced into the formed dyes. In examples, PhNH<sub>2</sub> is diazotized and coupled with Na 1-phenoxyacetyl-amino-8-hydroxynaphthalene-3,6-disulfonate in alk. medium. The product dyes wool in fast rose shades. PhNH<sub>2</sub> may be replaced by 2-aminobenzoic acid, 2-acetyl-amino-5-aminoanisole, 1-aminoacetanilide or *p*-xylidine, or these may be coupled with the 2(or 4)-chlorophenoxyacetyl, 2(or 4)-nitrophenoxyacetyl, 2-chloro-4-methylphenoxy- $\beta$ -propionyl or 1-(or 2)-naphthoxyacetyl derivs. of 1-amino-8-hydroxynaphthalene-3,6-disulfonic acid, or of the 1-ethylamino acid. The Na salt of the dye prepd. by coupling in acid medium 1 mol. of 4-nitro-1-aminobenzene-2-sulfonic acid with 1 mol. of 2-( $\omega$ -aminoethyl-amino)naphthalene-7-sulfonic acid is dissolved in water, Na<sub>2</sub>CO<sub>3</sub> is added and 2-chlorophenoxyacetic acid is added drop by drop with stirring and finally heating to 50°. The same dye which gives violet shades on wool may be obtained by prep. 2-[ $\omega$ -(2'-chlorophenoxyacetyl-amino)ethylamino]naphthalene-7-sulfonic acid and coupling it with diazotized 4-nitro-1-aminobenzene-2-sulfonic acid. 1-Aminobenzene-2,5-disulfo-*azo-p*-xylidine is diazotized and coupled with di-Na 1-(4'-chlorophenoxyacetyl-amino)-8-hydroxynaphthalene-4,6-disulfonate.

**Azo dyes.** I. G. FARBENIND. A.-G. Fr. 651,018, Mar. 19, 1928. Azo dyes are prepd. by coupling a diazo compd. of a dihalo-3-amino-1-toluene with a compd. capable of coupling and of dyeing vegetable fiber, *e. g.*, an arylamide of 2,3-hydroxynaphthoic acid. In an example, cotton is boiled in a liquid obtained by dissolving the 4-chloro-2-anilide of 2,3-hydroxynaphthoic acid in hot water with Turkey red oil and NaOH, cooling to about 50° and adding a little CH<sub>3</sub>O. The cotton is centrifuged and dipped for a min. in a soln. of diazotized 1-amino-2,4-dichloro-3-methylbenzene whereby a bright scarlet color is obtained. Several other examples are given.

**Azo dyes.** I. G. FARBENIND. A.-G. (Richard Stüsser, inventor). Ger. 475,341, Mar. 1, 1927. Azo dyes giving fast yellow shades on cotton and viscose silk are prepd. (a) by coupling sulfonic acids of 4,4'-diaminodiphenylurea or its derivs. with sulfonic acids of acetoacetic arylides, or (b) by converting *p*-aminosulfophenylazoacetoacetic arylidesulfonic acids into the corresponding urea, or (c) by coupling 4,4'-diaminodiphenylurea or its derivs. with unsulfonated acetoacetic arylides and sulfonating the product. In the examples, (1) 4,4'-diaminodiphenylurea-3,3'-disulfonic acid is tetrazotized and coupled with acetoacet-*o*-anilidesulfonic acid; (2) the monoazo dye from 4-nitroaniline-2-sulfonic acid and acetoacet-*o*-chloroanilide is sulfonated, reduced and the aminoazo compd. converted to the urea; (3) 5-nitro-2-anilidine-4-sulfonic acid is diazotized and coupled with acetoacet-*o*-anilidesulfonic acid; the product is reduced

with  $\text{Na}_2\text{S}$  and the aminoazo dye so obtained is treated with  $\text{COCl}_2$  to produce the urea. Cf. C. A. 23, 2041.

**Mono azo dyes.** WALTER DUISBERG, WINFRID HENTRICH and LUDWIG ZEH (to Grasselli Dyestuff Corp.). U. S. 1,711,930, May 7. Diazotized 2,4-dinitroaniline-6-sulfonic acid or other diazotized acid substituted dinitroaniline is combined with an acid substituted aromatic amine such as 2-amino-8-naphthol-6-sulfonic acid. Dyes thus formed are, in the form of their alkali metal salts, sol. in water and dye wool in an acid bath violet to blue shades fast to light and fulling.

**Dis- and poly-azo dyes.** I. G. FARBENIND. A.-G. Fr. 650,171, Feb. 28, 1928. Dis- and poly-azo dyes are prepd. by diazotizing or tetrazotizing amino- or diaminoazo dyes derived from arylenediaminecarboxylic acids, and coupling with any azo components, if necessary, in the presence of tertiary bases. The dyes may be diazotized again, either in substance or on the fiber and coupled with azo components, and the dyes obtained may be treated in substance or on the fiber with metal salts. Thus 5-nitro-2-aminobenzoic acid is diazotized and coupled in alk. medium with 2-amino-8-hydroxynaphthalene-6-sulfonic acid. The product is tetrazotized and coupled with *m*-phenylenediamine in alk. soln. The trisazo dye obtained dyes cotton green, and its fastness is increased by treatment with Cu salts.

**Blue tetrakisazo dyes for cotton.** HENRY JORDAN (to E. I. duPont de Nemours & Co.). U. S. 1,712,732, May 14. Blue tetrakisazo dyes for cotton are obtained by forming an intermediate by coupling a diazo compd. of a monoacyl-1,4-arylenediamine with an arylamine not contg. a free hydroxy group, diazotizing the intermediate, coupling the diazotized intermediate with 2-dinaphthylamine-5,5'-dihydroxy-7,7'-disulfonic acid and saponifying the product of the last-named coupling. The first components used in the process are the monoacyl-1,4-arylenediamines and their sulfonic acids. Among the suitable compds. which may be used are, *e. g.*, monoformyl-, monoacetyl- or monooxalyl-1,4-phenylenediamine, 2-acetyl-amino-5-aminoanisole, 2-oxalylamino-4-chloro-5-aminoanisole, 2-oxalylamino-4-methyl-5-aminoanisole and their sulfonic acids, monoacetyl-1,4-naphthalenediamine and its 6- or 7-sulfonic acid. As second components, comprising the amino compds. not contg. a free hydroxy group, there may be used, *e. g.*, *m*-toluidine, *p*-xylydine, cresidine, monoacetyl-*m*-toluylenediamine, 4-acetyl-amino-2-aminoanisole, other amino compounds of the benzene series suitable for another diazotization after having been coupled,  $\alpha$ -naphthylamine,  $\alpha$ -naphthylamine-6- or 7-sulfonic acid and  $\alpha$ -naphthylamine-2-methoxy-6-sulfonic acid. The dyes obtained by this process are, in their dry form, dark powders, dissolving in water with a reddish to greenish blue coloration, dyeing cotton from reddish to greenish blue shades, which on diazotizing and developing on the fiber with  $\beta$ -naphthol change only very little in color, but are remarkably increased in their fastness to washing. Those dyes having naphthalene derivs. as second components are superior, in their fastness to light, to the dyes having benzene derivs. as second components. The dyes are also characterized by their exceptional brightness. Several examples are given with details of procedure for making the dyes.

**Monoazo dyes of the pyrazolone series.** LEON W. GELLER (to National Aniline & Chemical Co.). U. S. 1,711,639, May 7. Dyes, giving orange-yellow to brown shades on wool in an acid bath changed to yellow-red to blue-red tints by after-chroming, and which are suitable also for making lakes or pigments, are formed by coupling diazo compds. of an *o*-aminonaphtholsulfonic acid, *e. g.*, 1,2-aminonaphthol-4-sulfonic acid or a similar compd. (which may contain a nitro group substituted in the naphthalene nucleus) with 1-aryl-5-pyrazolones of the benzene series which contain a sulfo group (and may also contain halogen as a substituent in the aryl nucleus), *e. g.*, 1-(4'-sulphophenyl)-3-methyl-5-pyrazolone (or 3-carboxylic acid). Cf. C. A. 23, 286.

**Vat dyes.** COMPAGNIE NATIONALE DE MATIÈRES COLORANTES ET MANUFACTURES DE PRODUITS CHIMIQUES DU NORD, RÉUNIES ÉTABLISSEMENTS KUHLMANN. Ger. 475,298, June 24, 1926. See Brit. 267,121 (C. A. 22, 1242).

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 651,152, Mar. 23, 1928. Vat dyes are obtained by condensing N-contg. dibenzanthrones, which have at least one active H atom attached to the N, with aromatic compds. contg. neg. substituents, preferably in the presence of high-b. p. solvents or diluents, and with or without catalysts and acid-binding agents. In examples, aminodibenzanthrone (from the  $\text{NO}_2$  compd. obtained by nitration of dibenzanthrone) is boiled with stirring for 15 hrs. in  $\text{PhNO}_2$  with  $\alpha$ -chloroanthraquinone,  $\text{NaOAc}$  and  $\text{CuCO}_3$ . The dye obtained is dissolved in  $\text{H}_2\text{SO}_4$  and pptd. with water. It dyes cotton in very fast shades from gray to black. Similar dyes are prepd. by condensing aminodibenzanthrone with  $\beta$ -chloroanthraquinone, dibromoanthanthrone (by brominating anthanthrone in the presence of halogen

carriers), trichloroanthraquinone-acridone, dibromoisodibenzanthrone, dichloro-*allo-ms*-naphthodianthrone (by chlorinating *allo-ms*-naphthodianthrone which is prepd. by alk. condensation of 2,2'-dimethyl-*ms*-benzodianthrone), tribromopyranthrone, nitrodibenzanthrone, nitronaphthalene, nitrobenzene and tetrabromopyranthrone. Nitrodibenzanthrone may be used along with reducing agents instead of the  $\text{NH}_3$  compd. A dye is also prepd. by condensing with tribromopyranthrone the compd. obtained by the action of  $\text{NH}_4\text{OH}$  on dibenzanthrone (see Ger 393,268).

**Vat dyes.** I. G. FARBENIND. A.-G. Fr. 651,679, Dec. 15, 1927. Valuable new vat dyes of the pyranthrone series are prepd. by treating with oxidizing or condensing agents the *Bz*, *Bz'*-diarylpyranthrone prepd. according to Ger. 278,424 by treating 1,1'-dianthraquinonyl-2'-bisarylketones or their derivs. with condensing agents having a reducing action. If oxidizing agents, *e. g.*,  $\text{MnO}_2$ , are used, the reaction in the simplest case probably takes place according to the following:

If non-oxidizing agents are used, *e. g.*,  $\text{AlCl}_3$ , the reduction compd. is obtained which is easily transformed to the dye itself. In examples, (1) *Bz*, *Bz'*-diphenylpyranthrone is dissolved in conc.  $\text{H}_2\text{SO}_4$  and a suspension of  $\text{MnO}_2$  in  $\text{H}_2\text{SO}_4$  is added with cooling and stirring. The dye is pptd. on pouring into water, it gives fast orange shades from the vat. (2) *Bz*, *Bz'*-diphenylpyranthrone is added to  $\text{AlCl}_3$  melted with  $\text{NaCl}$  at  $140^\circ$ , on bubbling air through the mixt. the same dye as in (1) is obtained.

**Vat dye.** I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 468,988, Jan. 15, 1927. A halogenated vat dye, prepd. by introducing halogen, with or without the aid of a catalyst, into *ms*-anthradianthrone (as obtained in Ger. 457,494), is suspended in 200 parts trichlorobenzene. I (0.5 parts) is added and  $\text{Cl}$  led in at  $150^\circ$  until the color of the reaction product is orange. The orange ppt., chloro-*ms*-anthradianthrone, is filtered off after cooling. Other examples are given. Cf. C. A. 23, 3106.

**Vat dyes.** I. G. FARBENIND. A.-G. (Max A. Kunz and Karl Köberle, inventors). Ger. 475,139, Jan. 25, 1927. Halo-*allo-ms*-naphthodianthrone or their derivs. are treated with aminoanthraquinones or their derivs. or with other compds. contg. a N atom to which at least 1 reactive H atom is attached. Solvents, diluents, catalysts and (or) acid-binding substances may be present. The products dye cotton in dark shades, and may or may not contain halogen, this depending on the selection of the initial materials. Examples are given describing the manuf. of dyes from (1) dibromo-*allo-ms*-naphthodianthrone and  $\alpha$ -aminoanthraquinone (dark marine blue shades); (2) dichloro-*allo-ms*-naphthodianthrone and 1-amino-4-methoxyanthraquinone (black shades); (3) dichloro-*allo-ms*-naphthodianthrone and  $\beta$ -aminoanthraquinone (copper-red shades); (4) dichloro-*allo-ms*-naphthodianthrone and *p*-toluenesulfonamide (violet shades); (5) tetrabromo-*allo-ms*-naphthodianthrone and 1-amino-2-methylanthraquinone (dark blue shades); (6) dichloro-*allo-ms*-naphthodianthrone and 1,5-diaminoanthraquinone (violet-black shades). The manuf. of the initial halo-*allo-ms*-naphthodianthrone is described in Ger. 457,493.

**Vat dyes.** KARL THIES, CARL J. MÜLLER, KARL SCHIRMACHER and KARL ZAHN (to Grasselli Dyestuff Corp.). U. S. 1,712,721, May 14. Dyes corresponding to the general formula:

wherein the benzene and naphthalene nuclei may be substituted are obtainable by condensing a 2,3-naphthoxythiophene compd. with an isatin compd. advantageously in the presence of an org. diluent and at elevated temp. and the process can be accelerated by the addn. of a small quantity of a mineral acid. In order to obtain dyes of the above given general formula which contain halogen as substituents, one may start with components contg. halogen or may introduce the halogen afterward into the condensation product. The dyes obtainable according to this invention dye wool and cotton fast red or bluish red shades. Examples are given of the use together of 2,3-naphthoxythiophene and 5,7-dibromoisatin, further bromination of the product of these two components, 2,3-naphthoxythiophene with isatin and subsequent bromination, 2,3-naphthoxythiophene with 5-bromo-7-methylisatin and Br, 2,3-naphthoxythiophene and 5,7-dichloroisatin with  $\text{SO}_2\text{Cl}_2$  and 2,3-naphthoxythiophene with 6-chloro-7-methylisatin and Br.

**Vat dyes formed by acid condensation of 2-benzanthronyl-1-aminoanthraquinones.** HUGO WOLFF (to Grasselli Dyestuff Corp.). U. S. 1,711,710, May 7. Vat dyes dyeing cotton orange-red to brown shades are obtained by heating, with acid condensing agents such as  $\text{H}_2\text{SO}_4$  and  $\text{H}_3\text{BO}_3$  or  $\text{AlCl}_3$  and  $\text{NaCl}$ , compds. such as 2-benzanthronyl-1-aminoanthraquinone, the condensation product formed from 2,6-dichlorobenzanthrone (1 mol.) and 1-aminoanthraquinone (2 mol.), 2-benzanthronyl-1-amino-6-chloroanthraquinone, the condensation product produced from equimol. proportions of 2-chlorobenzanthrone and 1,6-diaminoanthraquinone or the condensation product formed from equimol. proportions of 2,6-dichlorobenzanthrone and 1-amino-4-methoxyanthraquinone. Various examples and details are given.

**Vat dyes.** I. G. FARBENIND. A.-G. (Paul Nawiasky and Julius Müller, inventors). Ger. 475,342, Sept. 23, 1926. The aminobenzanthrone obtained by reducing the nitrobenzanthrone is heated with caustic alkali. The products give green or grey shades on cotton according to the conditions of manuf. Cf. Brit. 289,980 (C. A. 23, 989).

**Dyes derived from diphthalimidoanthraquinones.** ERNEST G. BECKETT and JOHN THOMAS (to Scottish Dyes, Ltd.). U. S. 1,711,873, May 7. Dyes are formed by nitrating a diphthalimidoanthraquinone such as 1,5-diphthalimidoanthraquinone and then treating the product with an alk. sulfide and a hydrolyzing agent such as  $\text{H}_2\text{SO}_4$ . The dyes thus obtained are suitable for producing blue shades on cellulose acetate, wool or other materials.

**Anthanthrone dyes.** I. G. FARBENIND. A.-G. Fr. 650,501, Mar. 6, 1928. Vat dyes of the anthanthrone series are prepd. by condensing halogen anthanthrones with aminoanthraquinones or their derivs. or substitution products in the presence of acid absorbing agents and substances having a catalytic action such as Cu or its compds. In an example, 2,7-dibromoanthanthrone is heated to boiling with  $\text{C}_{10}\text{H}_8$  and  $\alpha$ -aminoanthraquinone in the presence of  $\text{NaOAc}$  and  $\text{Cu}(\text{OAc})_2$  for 4–5 hrs. The reaction mass is extd. with solid naphtha and the residue boiled with dil.  $\text{HCl}$  and dried. The product dyes cotton from the vat in fast greyish blue shades. The dibromoanthanthrone, obtained by brominating anthanthrone in oleum, and  $\beta$ -aminoanthraquinone may also be used. 2,7-Dibromoanthanthrone may be condensed with 1-benzoylamino-4-aminoanthraquinone or the tri- or tetrabromoanthanthrone may be condensed with 3 or 4 mols. of benzoyl-1,5-diaminoanthraquinone.

**Triarylmethane dyes.** I. G. FARBENIND. A.-G. Brit. 299,473, Oct. 28, 1927. Leuco compds. (e. g., the leuco compd. from *v-m*-xylidine and benzaldehyde-2,4-disulfonic acid, the leuco acid from *o*-toluidine or *p*-xylidine and benzaldehyde-2,4-disulfonic acid, *p*-leucaniline or the leuco acid from *o*-cresotinic acid and benzaldehyde-*o*-sulfonic acid) are dissolved in pyridine, quinoline or like compds. or their mixts. and oxidized with mol. O in the presence of a Cu salt such as  $\text{CuCl}_2$ . Glycerol may partly replace the pyridine, etc., and alc. or water may be used as a diluent. Cf. C. A. 23, 716.

Brown dyes suitable for use on wool and leather. ROBERT SCHMIDLIN (to Grasselli

Dyestuff Corp.). U. S. 1,711,860, May 7. Quinone derivs. of  $\text{CO.CX:CR.CO.CX':CR'}$ , wherein R and R' represent radicals of the products obtained by the condensation of chloronitroaryl sulfonic and carboxylic acids with one amino group of an aromatic diamine which may be substituted, and X and X' represent H or a univalent substituent, constitute dyes which dye wool and leather (chrome leather) varied shades of good fastness. The condensation of benzoquinones with the said compds. may occur within wide limits as regards temp. and concn. Several examples are given and among the starting materials which may be used are: 4-nitro-4'-aminodiphenylamine-2-sulfonic acid and chloranil, Na aminonitrodiphenylaminesulfonate and chloranil, 5-methyl-4-amino-4'-nitrodiphenylamine-2'-sulfonic acid and toluquinone, Na (5-

amino-1-naphthyl)-4,6-dinitroaniline-2-sulfonate and toluquinone and Na 4-amino-5-methyl-4'-dinitrodiphenylamine-2'-carboxylate and toluquinone.

**Benzanthrone derivatives.** I. G. FARBENIND. A.-G. (Arthur Lüttringhaus, Hugo Wolff, and Heinrich Neresheimer, inventors). Ger. 475,476, June 16, 1925. Addn to 407,838. 2,2'-Dibenzanthronyl and its derivs. are prepd. by the alk. condensation under mild conditions of a 2-halobenzanthrone with benzanthrone or a deriv. not substituted in the 2-position. Asymmetrically substituted 2,2'-dibenzanthronyls useful as *dye intermediates* can be so prepd. The examples describe the prepn. of 2,2'-dibenzanthronyl, 6-methyl-2,2'-dibenzanthronyl, 6-chloro-2,2'-dibenzanthronyl, m. 312-314°, 7-chloro-2,2'-dibenzanthronyl, m. 305°, 6,6'-dichloro-2,2'-dibenzanthronyl, m. above 370° and 7,7'-dichloro-2,2'-dibenzanthronyl, m. above 370°.

**Cyanoarylthioglycolic acids.** I. G. FARBENIND. A.-G. Fr. 650,955, Mar. 16, 1928. *o*-Cyanoarylthioglycolic acids of the formula I are prepd. from *o*-aminoarylthiocyano compds. of the formula II: (I) (4)YAr[CN(1)][SCH<sub>2</sub>CO<sub>2</sub>H(2)], (II) (4)YAr[CN(1)][SCN(2)] in which Y signifies that the position *p*- to the NH<sub>2</sub> or CN group is substituted or blocked. The NH<sub>2</sub> group is replaced by CN by Sandmeyer's reaction, the SCN group is sapond. to a SH group and treated with monochloroacetic acid, the order of the first 2 steps being immaterial. The products are *intermediates for thioindigo dyes*. In examples, 1-methyl-2-cyano-5-chlorobenzene-3-thioglycolic acid (identical with the compd. mentioned in Fr. 478,107), 1-cyano-4-ethoxybenzene-2-thioglycolic acid, 2-cyanonaphthalene-1-thioglycolic acid and 1-methyl-2-amino-5-chlorobenzene-3-thioglycolic acid, m. 186°, are prepd.

**Dyes and intermediates.** SCOTTISH DYES, LTD. Fr. 650,976, Mar. 17, 1928. 3,3'-Dichloroanthraquinonehydrazine, which dyes cotton a bright reddish blue shade from the vat, is obtained by brominating 2-amino-3-chloroanthraquinone obtained by the process of Brit. 264,916. It may also be obtained by partially dechlorinating tri- and tetrachloroanthraquinonehydrazine (by direct chlorination of anthraquinonehydrazine). 3,3'-Dichloroindanthrone is prepd. by treating 1-bromo-2-amino-3-chloroanthraquinone (by brominating 2-amino-3-chloroanthraquinone) with a Cu salt in the presence of an acid absorbing agent in a solvent at the b. p.

**Dyes and intermediates.** I. G. FARBENIND. A.-G. Fr. 650,439, Mar. 5, 1928. Condensation products of the pyrenequinone series are obtained by treating 2-arylbenzanthrone with a condensing agent in the presence or not of O or air; the reaction taking place as follows:

The 2-arylbenzanthrone used are obtained by transforming 2-benzanthronecarboxylic acid, m. 307°, into its chloride and condensing with a hydrocarbon by the Friedel-Crafts reaction. Thus, when 2-benzoylbenzanthrone is condensed with AlCl<sub>3</sub>, 4,5,8,9-dibenzopyrene-3,10-quinone is obtained which dyes cotton from the vat in deep yellowish red shades. The products may be halogenated to give new dyes. *p*-Bromobenzoyl-2-benzanthrone is condensed with the double chloride of Al and Na, giving monobromo-4,5,8,9-dibenzopyrene-3,10-quinone which dyes cotton orange-red from the vat. 2-Toluybenzanthrone and  $\alpha$ -naphthoyl-2-benzanthrone are condensed in the same way. The chlorination and bromination of 4,5,8,9-dibenzopyrene-3,10-quinone, giving different vat dyes, are also exemplified.

**Dye intermediates.** I. G. FARBENIND. A.-G. Brit. 299,327, Oct. 22, 1927. Halogen arylthioglycolic acids are formed from primary aromatic amines having a free *p*-position, by introducing a CNS group into this position by treating with an inorg. sulfocyanate and a halogen (suitably Br and NaCNS in MeOH) to form a mercapto group, converting the latter by condensation with chloroacetic acid into a thioglycolic acid group and then replacing the NH<sub>2</sub> group by halogen by Sandmeyer's reaction.

**Dyes and lakes.** I. G. FARBENIND. A.-G. Brit. 299,332. Azo dyes are formed in substance, on the fiber or on a substratum by coupling a diazotized 2,3-aminonaphthoic ester or a substitution product with a naphthol or with an arylide of 2,3-hydroxynaphthoic acid or a substitution product. Several examples are given of dyes which in general give bluish red colors. Products may be formed suitable for dyeing fabrics, coloring wall papers or for use in paints. Cf. C. A. 22, 2065.

**Oxidation in dyeing.** EUGÈNE SCHUELLER. Fr. 650,755, Mar. 12, 1928. In dyeing textiles, skins, hair, etc., the treatment by oxidation, by the aid of peroxides, with or without catalysts of the nature of peroxydases, is combined with a treatment by agents to bring about rapid pptn. of the oxidation products, *e. g.*, alkali or alk. earth chlorides which have a phys. action, or metallic salts which combine with the oxidation products.

**Dyeing artificial silk.** WINFRID HENTRICH, RUDOLF KNOCH and MAX HARDT-MANN (to Grasselli Dyestuff Corp.). U. S. 1,711,890, May 7. Org. cellulose esters or ethers are treated with azo dyes obtainable from aromatic diazo compds. contg. an acid group such as diazotized aniline-4-sulfonic acid and  $\alpha,\gamma$ -diketohydrindene or a deriv. Yellow to orange dyeings are obtained. Cf. C. A. 23, 527.

**Dyeing artificial silk.** BRITISH DYESTUFFS CORP., LTD., JAMES BADDILEY, PERCY CHORLEY and CARLTON BUTLER. Ger. 475,125, Mar. 8, 1927. Addn. to 474,430 (C. A. 23, 3110). See Brit. 276,757 (C. A. 22, 2471).

**Dyeing cellulose esters and ethers.** BRITISH CELANESE, LTD., G. H. ELLIS, H. C. OLPIN and E. W. KIRK. Brit. 299,343, July 19, 1927. Dyeing, printing or stenciling is effected with dyes obtained from naphthylenediamines or their nuclear substitution products. Various examples of monoazo and disazo dyes formed from components of the benzene and naphthalene series are given and specific dyes giving red shades are described.

**Dyeing cellulose esters and ethers.** BRITISH CELANESE, LTD., G. H. ELLIS and H. C. OLPIN. Brit. 299,349, July 20, 1927. Dyeing, printing or stenciling is effected with compds. obtainable by introducing at least one  $\beta$ -ketoacyl group into dyes contg. amino groups, which may be of the azo, nitrodiarylamine, nitrodiaryl, nitrodiaryl-methane or anthraquinone series and are usually unsulfonated. Numerous examples are given. When the dyes contain diazotizable amino groups, the dyeings may be diazotized and developed on the fiber.

**Cross-dyeing cellulosic fabrics.** JOHN C. WATSON (to B. B. & R. Knight Corp.). U. S. reissue 17,295, May 14. See original pat. No. 1,629,769 (C. A. 21, 2388).

**Dyeing vegetable fibers.** I. G. FARBENIND. A.-G. (Arthur Zitscher, inventor). Ger. 475,553, May 29, 1925. Addn. to 467,545. The method of Ger. 467,545 (C. A. 23, 993) is modified by using diazo compds. derived from amines substituted in the positions described therein but contg. instead of or in addn. to Cl, a group  $-\text{SO}_2\text{R}$  or  $-\text{COR}$ , where R is an alkyl, aryl or aralkyl residue which may be a simple residue or an amine or amide residue or, if aryl, may be a residue from a ketone, a sulfone or a thio- or carboxy-arylide, and may in any case be further substituted. The use of certain derivs. of *m*-aminobenzoic acid is excluded. The use of the diazo compds. from 2-aminotolyl-4-phenylsulfone and 4-chloro-3-aminobenzanilide is described by way of example, blue and yellow shades, resp., being obtained. A list is given of the shades obtained with a no. of other diazo or tetrazo compds. derived from amines of the kind specified. Cf. C. A. 23, 1759.

**Dyeing or sizing yarns.** ADOLF H. JUNKERS. Ger. 475,118, June 15, 1924. In dyeing or sizing yarns by the method in which the yarn is wound on hollow perforated tubes into which the liquid is forced, the tubes have a comparatively large internal diameter, and the outer surface of the yarn is pressed mechanically or by hand during the treatment.

**Transforming dyed colors.** AUSTRALINE COLOR TRANSFORMERS PROPRIETARY, Ltd. Australia 11,587, Feb. 6, 1928. Dyed colors in fabrics are made lighter by subjecting the material to the action of a mixt. contg. an agent to break down the fixing substance of the dye and substances to bleach the dye slowly. *E. g.*,  $\text{NaOAc}$  1.5 oz., Na thiosulfate 0.5 oz.,  $\text{H}_2\text{O}_2$  0.5 pint, water 1 gallon.

**Dyeing apparatus.** LÉON L. MERCIER and PIERRE J. MERCIER. Fr. 651,408, Mar. 15, 1928. The dyeing vats are made of glass, several of which are mounted over a common liquid-collecting closed channel or box.

**Apparatus for dyeing hanks with vat dyes.** JOAQUIN TARRAGÓ BESCÓS. Ger. 475,281, Mar. 31, 1926.

**Apparatus for dyeing elastic textiles.** WILLY HALSTENBACH. Fr. 651,655, Mar. 23, 1928.

**Machine for dyeing cloth.** ÉTABLISSEMENTS BENNINGER S. A. Fr. 650,173, Feb. 28, 1928. Means for reversing the direction of travel of the cloth through the dye bath are described.

**Treating freshly dyed materials with illuminating gas.** JOHN MACADAM (to Joseph Bancroft & Sons Co.). U. S. 1,712,044, May 7. Freshly dyed materials are passed through an atm. of illuminating gas or other inert or non-oxidizing gas immediately after subjection to a reducing agent and before treatment with an oxidizing agent such as a dichromate or peroxide soln. in order to control the treatments. An app. is described.

**Use of iron carbonyl in printing textile materials.** I. G. FARBENIND. A.-G. Brit. 299,210, Nov. 25, 1927. Iron carbonyl is used in either printing pastes or discharges, examples of which are given. After steaming, the goods may be treated with oxalic acid to remove the iron oxide.

**Sulfurized products.** SOC. ANON. POUR L'IND. CHIM. À SAINT-DENIS. Fr. 650,614, Mar. 9, 1928. A sulfurized product useful for *fixing basic dyes* is obtained by heating together a cresol and a phenol (PhOH, naphthol, resorcinol) in alc. soln. in the presence of S, HF and a catalyst (salt of Al, Sb, or I) and passing a current of air and HCl through the mixt. during the reaction. Excess alc. is afterwards removed, and the residue is heated for several hrs. in an alk. carbonate soln. In an example the starting mixt. contains PhOH 10, cresylic acid 2, MeOH 40, NaS 5, S 2, SbO 0.2, HF 0.1 kg. Fr. 650,615 describes a sulfurized product which may be used as a *wetting or mercerizing agent* obtained by mixing a phenol, cresol, naphthol or resorcinol in alc. soln. with an aldehyde, heating for several hrs. in the presence of a catalyst, making alk., eliminating the alc. and heating the residue for several hrs. with a mixt. of ordinary H<sub>2</sub>SO<sub>4</sub> and oleum. The product is washed with salt water and neutralized. In an example the following are used: MeOH 40, trioxymethylene 15, naphthol 5, AlCl<sub>3</sub> 0.5, phenol 10, H<sub>2</sub>SO<sub>4</sub> (66° Bé) 3, oleum 1 kg.

**Apparatus for lenosating vegetable fibers.** CHARLES LIÉNARD-FIEVET. Fr. 651,630, Mar. 12, 1928.

**Fiber and yarn from flax straw.** M. WADDELL and H. C. WATSON. Brit. 299,519, July 29, 1927. Flax stalks are dried to harden their gummy constituents and render the woody stalks and seed balls dry and brittle, divided into pieces convenient for handling, broken or crushed, scutched, hackled and carded. Fibers thus prepd. are formed into a rope or rove, wound on a reel and retted by bacteria or chemicals and subjected to washing and other desired treatments.

**Apparatus for coating textile threads with powdered metal or solid coloring matter in suspension in liquids.** W. RÖSSING. Brit. 299,219, Dec. 9, 1927. Structural features.

**Coating fabrics with rubber, etc.** A. N. PARRETT (to Imperial Chemical Industries, Ltd.). Brit. 299,321, Oct. 22, 1927. Rubberized fabrics (which may also be varnished) are further coated with a pyroxylin compn. which adheres well to the rubber surface and is sufficiently distensible and pliable to avoid cracking or peeling. Numerous details, formulas and examples of suitable compns. are given.

**Apparatus for conditioning yarn by treatment with steam.** FRANK L. FURBUSH (to C. G. Sargent's Sons Corp.). U. S. 1,713,429, May 14.

**Silk.** I. G. FARBENIND. A.-G. Fr. 650,253, Mar. 1, 1928. Natural and artificial silk are mixed in the desired proportions, carded together and submitted to the usual textile operations.

**Artificial silk.** BENNO BORZYKOWSKI. Fr. 650,747, Mar. 12, 1928. See Brit. 287,073 (C. A. 23, 513).

**Weighting artificial silk.** RENÉ CLAVEL. Ger. 471,370, Nov. 2, 1927. Addn. to 468,018 (C. A. 23, 2306). The acids or acid salts employed in raising the acid concn. of the metal-salt bath for weighting artificial silk according to the method of the prior patent, is incorporated, by impregnation or coating, with the silk. Thus a mixt. of acetate and viscose silk is steeped in a soln. contg. 20 cc. basic H<sub>3</sub>PO<sub>4</sub> and 10 g. EtOH per liter, and squeezed out, before immersion in the weighting bath of ZnCl<sub>2</sub> soln.

**Washing artificial silk.** HERMINGHAUS & Co. G. M. B. H. Ger. 475,035, Feb. 15, 1925. Relates to the washing of artificial silk spun on perforated holders. The holders are stood vertically and closed at the lower ends, and a predetd. amt. of washing liquid is fed to the interior of each holder from a vessel placed above the holders, the liquid passing through the silk merely under the slight pressure due to the head of liquid. The holders are inverted at a suitable stage of the process. Cf. C. A. 23, 3111.

**Apparatus for the treatment of cops of artificial silk fibers.** WULF SCHULZ. Ger. 469,845, Apr. 14, 1926. The cops are mounted on spindles under tubes for acidify-

ing, drying, bleaching, or washing them, according to the nature of the substances introduced into the tubes.

**Apparatus for re-winding artificial silk.** I. G. FARBENIND. A.-G. Brit. 299,399, (Oct. 25, 1927. An app. is described suitable for use in the process described in Brit. 297,744 (C. A. 23, 2823).

**Spinning artificial textile filaments to resemble natural fibers.** W. SEVER and J. B. SPEAKMAN. Brit. 299,291, April 3, 1928. Artificial filaments having a curl or wave similar to natural fibers are formed by extrusion of a suitable spinning soln. into a coagulating medium while causing pulsations of flow of either the coagulating medium or of the soln. being spun. An app. is described.

**Washing artificial threads.** THE NUERA ART-SILK CO. Ger. 475,247, Nov. 16, 1927. The threads leaving the pptg. bath are wound on a bobbin, which rotates alternately within and above a washing bath, the arrangement being such that the pptg. liquid carried on the threads is dild. in the washing bath and the dild. liquid thrown off when the bobbin rotates above the bath.

**Buckram.** SAMUEL HARARY. U. S. 1,712,991, May 14. In prepg. a pattern material for embroidery purposes, the fabric is sized with an acid resist such as starch and then satd. with dil. HCl and dried.

**Bleaching cloth.** ETIENNE ACZEL. Fr. 651,640, Mar. 23, 1928. Fibrous material is bleached by passing it between or around the electrodes of an ozonizer. Suitable forms of app. are described.

**Bleaching cotton.** HERAEUS-VACUUMSCHMELZE A.-G. and WILHELM ROHN. Ger. 475,123, May 26, 1927. In bleaching cotton, particularly with hypochlorites, the cotton is wound on externally enameled bobbins or tubes made of Cr-Ni alloy, if desired, with addns. of Fe, Mo, W or Co, or made of Ni, German silver or Monel metal.

**Heater for bleaching, etc., lyes.** ERNST WERNER. Ger. 475,121, May 2, 1926. Addn. to 457,679. The lyes ascend an annular space in which a heating worm is closely fitted. One or both of the walls of the space are heated by steam jackets.

**Centrifugal separator suitable for treating wool washing water.** AKTIEBOLAGET SEPARATOR. Brit. 299,422, Oct. 26, 1927. Structural features.

**Purifying liquids used for "dry cleaning."** GUTHRIE B. BOON (to R. R. Stolley, (Inc.)). U. S. 1,711,829, May 7. Solvent liquids such as gasoline are treated with a caustic soln. and most of this caustic is then sepd. by passing the solvent through a body of water. Remaining traces of caustic are removed by use of  $\text{CaCl}_2$ . An app. is described.

**Cleaning soiled "dry cleaning" liquids, etc.** EUSTACE A. ALLIOTT, CHESHAM BORS and ARTHUR E. HATFIELD. U. S. 1,713,317, May 14. Soiled liquid from washing app. such as that used for "dry cleaning," laundry washing, wool scouring, etc., is mixed with a "filter aid," and the quantity of the latter mixed with the liquid, during part of the cleaning operation at least, is diminished as the mixt. passes to a filter. An app. is described.

## 26—PAINTS, VARNISHES AND RESINS

A. H. SABIN

**Paint technology.** LOUIS A. JORDAN. *J. Soc. Chem. Ind.* 48, 13-21T(1929).—J. briefly reviews some of the recent developments and theories of paint technology. X-ray examn. of pigments indicates the importance of the presence of small amounts of impurities. Determination of particle size of pigments is fundamental in connection with the proper use of pigments. Recent work suggests that fine grinding of pigments may be overdone. Surface activity and adsorption are important in relation to the wetting of pigment by oil and to stability of the dispersed pigment. Producing the proper adsorption film on pigment particles before suspending in oil may alter the entire character of the resulting paint. Recent work on the drying of oil and the proper use of oil driers is discussed. The maturing of varnishes, effect of ultra-violet light on oils, and the cause of "bloom" on varnish films also are considered. L. B. MILLER

**Testing of paint films.** E. RITTER. *Korrosion u. Metallschutz* 5, 64-7(1929).— $\text{Ag}_2\text{CrO}_4$  in gelatin was used to coat one side of a glass plate and then the paint to be tested was put on the gelatin. A waterproof covering was put around the edges of the plate and the whole immersed in chloride solns. at const. temp. At the points penetrated by  $\text{Cl}^-$  ions spots of  $\text{AgCl}$  formed, indicating the extent of penetration of the paint film. The gelatin film was unaffected by light. The effect of the gelatin upon the paint was not detd. With variations in temp. some of the films which showed no spots at

const. temp. were attacked. An app. is described in which the plates could be exposed to varying temps., humidity and ultra-violet light. B. E. ROETHELI

**Comparative analyses of water paints and paint emulsions.** FRIEDRICH WAGNER. *Farbe u. Lack* 1929, 187-8, 204-5. Tables are given showing the percentage compn. of various com. water paints and emulsion paints with special reference to the proportions of water, oil, adhesive and pigment. G. G. SWARD

**Aluminum pigments as heat-resisting paints.** OTTO MERZ. *Arch. Wärmewirt.* 10, 156-7(1929).—Two tables are given showing the wearing qualities of Al and Al bronze pigments in various vehicles at various temps. up to 500°. E. W. T.

**Yellow pigments for facades.** ANON. *Farbe u. Lack* 1929, 167.—The main requirements are stability toward light and lime. The first requirement excludes all coal-tar colors while the second excludes most of the artificial mineral colors, such as chrome yellows, yellow ultramarine, etc. The others are the only reliable pigments for this purpose. G. G. SWARD

**Lead soaps.** MANFRED RAGG. *Farben-Ztg.* 34, 1605-9, 1661-4(1929).—All basic Pb pigments react with fatty acids to form true soaps of pronounced anisotropic character showing spherulites and needles in polarized light. The soaps are slightly sol. in cold oils and org. solvents. At moderate heat PbO is sol. in linseed oil, forming complex compds. contg. glycerol which differ from true Pb soaps in their compn. and morphological properties. When red lead is dissolved in hot linseed oil, the intermediate formation of PbO<sub>2</sub> can be shown. The PbO<sub>2</sub> is reduced to PbO. In aged paint films contg. red lead, white lead and "Tego," the presence of mixts. of true Pb soaps and complex glycerides can be proven analytically and microscopically. The bulk of the org. Pb compds. in paint films consists of an amorphous isotropic sol. The supposition that these Pb compds. have a strengthening effect on the film is therefore erroneous. G. G. SWARD

**Determination of oil requirement of pigments.** C. P. VAN HOEK. *Farben-Ztg.* 34, 1784-5(1929).—The lab. method of adding the oil to the pigment is the reverse of the general factory practice of adding the pigment to the oil. The former method yields high results. By the Gardner-Coleman method as modified by Fasig and by Wolff (mortar and pestle), 100 g. ZnO formed a paste with 18.6 g. linseed oil when the pigment was added to the oil. When, however, the oil was added to the pigment, 26 g. oil was required. To the latter paste, however, 30 g. of pigment could be added without its losing the properties of a paste, thus restoring the ratio, pigment : oil = 100 : 18.6. The paste thus formed was "shorter" than the one prepd. by adding pigment to oil. Similarly, putty prepd. by adding oil to chalk is always shorter and stickier and more difficult to work than putty prepd. by adding chalk to the oil. G. G. SWARD

**The iodine number of fatty drying oils.** VON REIBNITZ. *Farben-Ztg.* 34, 1782-4(1929).—The Hanus, Hübl-Waller and Wijs iodine numbers of raw and bodied linseed and tung oils were found to increase with increase of temp. and length of the reaction period. The Wijs method is recommended for speed, reliability and reproducibility. G. G. SWARD

**Wood oil and wood oil substitute.** JOHANNES SCHEIBER. *Farbe u. Lack* 1929, 153-4.—The instability of pure wood oil films is due to the eleostearic acid and its triply conjugated bonds, which imparts pronounced polymerization characteristics. These polymerization characteristics eventually lead to the destruction of the film. If the elements of water be removed from ricinoleic acid by appropriate means an acid with doubly conjugated bonds results. This acid may be readily esterified with glycerol to form a drying oil with many of the desirable and with but few of the undesirable properties of wood oil. G. G. SWARD

**Australian standard specification for China wood oil.** ANON. *Australian Commonwealth Eng. Standards Assoc.* (Sydney) No. K-11, 18 pp.(1929).—Specifications cover color, sp. gr.,  $n$ , I value, sapon. value, acid value and standard methods of sampling and testing. E. I. S.

**Tung oil. III.** D. HOLDE, W. BLEYBERG AND M. A. AZIZ. *Farben-Ztg.* 34, 1725-6(1929); cf. C. A. 23, 1761, 2049.—To ascertain if the hydroaromatic derivs. were present, as previously suggested, the dehalogenated products were oxidized with KMnO<sub>4</sub> or chromic acid and tested for the presence of phthalic acid. The resorcinol-H<sub>2</sub>SO<sub>4</sub> fluorescence test was modified by heating the sample with addn. of H<sub>2</sub>SO<sub>4</sub> to 205-10°. No evidence of phthalic acid was found. G. G. SWARD

**The use of mineral oils in "running" copals.** B. SCHNEFEL. *Farben-Ztg.* 34, 1786(1929).—Pyhäliä (cf. C. A. 23, 3113) is adversely criticized on the grounds that complete "running" of the copal and complete removal of the mineral oil were not shown. G. G. SWARD

**Determination of viscosity of oils and varnishes by the air-bubble method.** RUCHTI. *Farben-Ztg.* 34, 1899-1901(1929).—R. describes a frame for holding the viscometer tubes vertical. A comparison is given of Engler degrees and the bubble values for tubes 0.80 cm. internal diam. G. G. SWARD

**Australian standard specifications for varnishes.** *Australian Commonwealth Eng. Standards Assoc.* (Sydney) Nos. K-14 to 16, 25 pp.(1929).—Specifications cover classification, color, rates of drying, viscosity, volatile matter, etc., for interior oil varnish, exterior oil varnish and flattening or rubbing varnish. Standard methods of sampling and testing are included. **Genuine red lead, dry.** *Ibid* No. K-19, 16 pp.(1929).—Specifications cover compn., color, org. coloring matter, coarse particles, volatile matter and standard methods for sampling and testing. **Lithopone.** *Ibid* No. K-20, 16 pp.(1929).—Specifications cover compn., coarse particles, color, reducing power, volatile matter and standard method of sampling and testing. **Linseed oil putty.** *Ibid* No. K-27, 15 pp.(1929).—Specifications cover compn., condition, and standard methods of sampling and testing. E. I. S.

**Thickening of varnish paints.** HANS WOLFF AND R. SINGER. *Farben-Ztg.* 34, 1840-1(1929).—The addn. of fatty acids or their metallic soaps and other org. acids inhibits or reduces the thickening of lacquers contg. red lead (ordinary or dispersed) or clay, but had no effect on those containing ZnO. Alcs. and ketones sometimes produced a like effect which may have been due to the presence of acids. The phenomenon is probably phys. and may be due to an absorption of the reagent by the pigment or to a change in the charge on the pigment or liquid. The behavior of oil systems should be analogous to that of lacquers. G. G. SWARD

**Explosions of lacquer drying ovens.** ANON. *Feuerungstech.* 17, 21-2(1929).—Expts. on a small-scale oven showed that even at 180-190°, which is far below the ignition temp. of the vapors, spontaneous ignition may occur if drops of solvent are allowed to evaporate from an iron surface. With Al no ignition occurred at 300°. E. W. T.

**Baking of japans and shivel finishes on phonograph parts.** I. STANLEY WISHOSKI. *Fuels and Furnaces* 6, 1695-1704(1928). L. B. MILLER

**Acid values of resins.** ERICH STOCK. *Farben-Ztg.* 34, 1727(1929).—The acid values of 19 different resins, both synthetic and natural, were detd. in alc.-benzene and according to the "Albert indirect method." The agreement was good. G. G. S.

**Oilcloth and its manufacture.** P. MARTELL. *Kunststoffe* 19, 28-30(1929).—The history of oilcloth and its manuf. are described. B. HAMILTON

**Pyroabietic acids from French rosin (FONROBERT, GRETH) 10.** Abrasion apparatus for determining the wearing qualities of linoleum (U. S. pat. 1,711,866) 1.

**BITMEAD, RICHARD: French Polishing and Enameling.** 9th ed. London: Crosby Lockwood. 120 pp. 2s. 6d. net.

**JAEGER, PAUL: Das Problem der Leinöltechnik und seine natürliche Lösung.** Feuerbach-Württ: Forschungs- u. Lehrinstitut für Anstreichtechnik. 53 pp.

**MARGIVAL, FRANCOIS: Encres nouvelles.** Preparation des encres noires et de couleurs. Encres fixes et à copier. Traçage. Effaçage. Revivification des traits pâles. Paris: Desforges, Girardot et Cie. 178 pp.

**SCOTT, WINFIELD G.: Formulas and Processes for Manufacturing Paints, Oils and Varnishes; A Laboratory Manual.** Chicago: Trade Review Co. 223 pp. \$4.50.

**WOLFF, HANS, SCHLICK, W. AND WAGNER, HANS: Taschenbuch für die Farben- und Lackindustrie sowie für den einschlägigen Handel.** Revised and enlarged ed. Stuttgart. Wissenschaftliche Verlag. m. b. H. 382 pp. Linen, M. 11.

**Linseed oil varnishes.** I. G. FARBENIND. A.-G. Brit. 299,361, Oct. 24, 1927. Deposition of driers in linseed oil varnishes is prevented by converting the free fatty acid in the oil into salts such as those of Ca, Mg, Zn or Cd.

**Lacquer.** INTERNATIONAL FIREPROOF PRODUCTS CORP. Fr. 650,736, Mar. 10, 1928. See Brit. 286,724 (C. A. 23, 532).

**Lacquers.** I. G. FARBENIND. A.-G. Fr. 650,814, Mar. 13, 1928. Lacquers are prepd by mixing solns. of oxygen with solns. of nitrocellulose with or without softening agents, resins or the like. Thus, a soln. of celluloid wool in AcOAm or AcOBu is mixed with an alc. soln. of linoxyn. Tricresyl phosphate may be added, and if too thick the lacquer may be thinned with alc., AcOAm, acetone, etc.

**Nitrocellulose lacquer as a sealing for dry cell batteries.** PAUL A. MARSAL (to National Carbon Co.). U. S. 1,711,739, May 7. See Can. 282,684 (C. A. 22, 4070).

**Printing ink.** JACQUES G. AULAGNE and JULES J. SOUCHON. Fr. 651,217, Dec 30, 1927. A printing ink consists of a metallic powder such as Au, Ag or bronze in a colorless varnish.

**Dammar resins.** LOUIS BLUMER. Fr. 651,631, Mar. 13, 1928. Dammar resins are improved for use in the manuf. of varnishes having a basis of cellulose esters by elimination of the  $\beta$ -dammar resin. The resins are treated with solvents such as alcs., ethers, acetone,  $C_6H_6$  and mixts. of  $C_6H_6$  or toluene and EtOH, which dissolve the dammaric acid and the  $\alpha$ -resin, but not the  $\beta$ -resin.

**Colophony.** LOUIS G. L. DÉSALBRES. Fr. 651,648, Mar. 23, 1928. Black rosin tars are distd. in vacuum for the production of colophony; 0.2–0.3% of hydroquinone may be added to the tar.

**Resin solutions.** SOC. D'EXPLOITATION DE BREVETS ET PROCÉDÉS P. N. Brit. 299,293, Oct. 22, 1927. The process of forming aq. resin-bearing fluids described in Brit. 263,393 (C. A. 22, 165) by treating resin, without heating, with caustic alkali soln. is modified by replacing the cold solns. of caustic alkali by cold solns. of other sol. mineral or org. bases or their salts of less concn. than that which would cause pptn or salting-out of the resinate of the base and using only such salts as are formed from acids with a weaker disson. constant than that of the resin acids present.

**Synthetic resins.** I. G. FARBERIND. A.-G. (Gerhard Balle and Karl Daimler, inventors). Ger. 475,478, Feb. 2, 1922. Resinous compns. which can be hardened by heat are prepd. by mixing the resinous or pitchy condensation products from  $SOCl_2$  and tar oils, tars, pitches and like aromatic hydrocarbons with reactive resins of the  $PhOH \cdot CH_2O$  type. Cf. C. A. 23, 3115.

**Synthetic resins.** R. H. KIENLE (to British Thomson-Houston Co., Ltd.). Brit. 299,424, Oct. 26, 1927. A "polybasic" acid such as phthalic acid is condensed with a monohydric and a polyhydric alc. such as glycerol and amyl, butyl, allyl or diacetone alc. or phenol or borneol; the polybasic acid may in part be replaced by a monobasic acid such as oleic acid. The use of succinic, maleic, fumaric, citric, sebacic, tartaric and oxalic acids and of glycol and EtOH is also suitable. Fusible and sol. products are first obtained by heating in stages at  $160^\circ$  and  $200\text{--}20^\circ$  and these products may be rendered infusible and insol. by further heating for several hrs. at  $150\text{--}200^\circ$ . Cf. C. A. 22, 4844.

## 27—FATS, FATTY OILS, WAXES AND SOAPS

E. SCHERUBEL

**Pachira aquatica Aubl.** J. PIERAERTS. *Mat. grasses* 20, 8279–80, 8335–7(1928); cf. C. A. 22, 4000.—The characteristics of the oil obtained from this plant are practically identical with those of palm oil. The economical value is stressed and its cultivation advocated in Africa. In the last article its properties and characteristics are compared with those of oils of various origins.

**Animal and vegetable fats and oils.** U. S. Census Bur. 1928, 18 pp.—Production, consumption, imports, exports and stocks are given by quarters for 1926 and 1927.

E. J. C.

**Systematic classification of fats. II. Proposed classification of vegetable fats according to scientific and practical viewpoints.** W. HALDEN. *Graz. Med. Chem. Inst. Chem. Umschau Fette, Oele, Wachse u. Harze* 36, 109–15(1929); cf. C. A. 22, 2072.—A new classification is proposed for vegetable fats and oils, based on the botanical grouping by Engler and Gilg ("Syllabus der Pflanzenfamilien"). There are 37 botanical families, the members producing mainly drying oils; 64 families producing non-drying oils and fats; 14 families with members among both, the drying and non-drying oils, and 1 family (castor plant) which necessitated a 3rd division. The botanical character of the plants takes preference over the chem. properties of their oils. Members of one family produce mostly one type of oil and certain relationships exist between the oils of adjacent groups.

P. ESCHER

**The field of fats. XIII. Partial halogen addition to multiply unsaturated fatty acids.**  $\beta$ -Eleostearic acid glyceride and wood oil. H. P. KAUFMANN WITH CH. LUTENBERG. *Univ. Jena. Ber.* 62B, 392–401(1929). Eleostearic acid (I) and its glyceride, (II), which are readily available and can be prepd. in pure form, afforded welcome exptl. material in K.'s search for a method of partial halogen addn., which could be detd. quantitatively by titration. It had already been shown that in the action of Br in MeOH (satd. with NaBr) on II there is a distinct halt in the addn., corresponding to the consumption of 2 mols. Br; on continuing the action for several days, 1 nos. approaching

that corresponding to 3 double bonds are obtained; the latter is reached quickly with Br in  $\text{CCl}_4$  in the light of a uvial lamp. Hitherto, however, it had not been possible to obtain titrimetrically with halogen a definite halting point corresponding to 1 double bond, such as can be secured with  $(\text{SCN})_2$ . The object of the present work was to obtain a sharper endpoint in the addn. of Br to 2 double bonds and to establish, if possible, the conditions for adding halogen, in a titrimetrically controllable manner, to 1 double bond. By using Br in  $\text{CCl}_4$  in the dark on pure II and Chinese wood oils, the values obtained for 2 double bonds are so const., as compared with the results of other methods hitherto known, that the process is recommended for the detn. of the I no. of the wood oils. Addn. of  $\text{KIO}_3$ , at the end of the detn., and titration of the I liberated by the acid present, shows that only a very slight amount of acid is formed in the process and that therefore no appreciable substitution has occurred. If, however, the I no. detn. is made with Br in MeOH satd. with NaBr instead of in  $\text{CCl}_4$ , and  $\text{KIO}_3$  is added at the end of the expt., almost all of the halogen is recovered. Substitution of alc. NaI for the aq. KI had no detectable influence on the results. To effect with halogens what had already been accomplished with  $(\text{SCN})_2$ , i. e., addn. to only 1 double bond, it was necessary to diminish greatly the reactivity of the halogen. Numerous attempts were made to secure this result by using substances holding Br in loose combination, such as org. perbromides (azobenzene perbromide), but none of these solns. fulfilled the condition of titrimetric constancy. The desired object was finally attained by combining the Br in MeOH not only with NaBr but also with I; numerous trials showed that the best results were obtained by using equiv. amounts of Br and I in NaBr-MeOH and by dissolving the fat in equal vols. of  $\text{CHCl}_3$  and  $\text{CCl}_4$ . C. A. R.

**Distinguishing between expressed and extracted cacao butter.** AUFRECHT. *Chem.-Ztg.* 53, 318(1929).—Dissolve 2 g. cacao butter in 5 cc.  $\text{CHCl}_3$  in a test tube. Mix the clear soln. with 5 cc. HCl (d. 1.192). A light green color in the lower layer, followed by a dark green in 1 min. indicates extd. cacao butter. By adding 2 drops of  $\text{HNO}_3$  (d. 1.42), and heating to  $50^\circ$  a reddish brown color is produced in 2 mins. Ext'd. residues give a brownish yellow color, which in 5 mins. changes to a brown-violet. Expressed cacao butter remains unchanged when treated as above. E. SCHERUBEL

**Formation of toxic gases in the manufacture of washing compounds containing trichloroethylene.** WELWART. *Seifensieder-Ztg.* 56, 26(1929).—Toxic gases were formed when a fresh lot of  $\text{C}_2\text{HCl}_3$  washing compd. was made by charging the kettle with the required amt. of solid KOH, which on coming into contact with a few l. of liquor left in the kettle from the last operation formed a concd. hot KOH soln. This decomposed the  $\text{C}_2\text{HCl}_3$  into formate, CO,  $\text{C}_2\text{H}_4$  and traces of dichloroacetylene, which latter caused spontaneous ignition of the mass after a sufficient amt. had accumulated.

P. ESCHER

**The "Wecker" method.** C. H. KRUTGEN. Marburg. *Seifensieder-Ztg.* 56, 145 6(1929).—An answer to "Kronos" (C. A. 23, 2587).—The "Wecker" method has been slowly developed through many years and factory results are now cited for both the fatty acid distn. and the removal of free fatty acids from oils. In the latter case the removal is carried down to  $1\frac{1}{2}\%$  free fatty acids, and the remaining  $1\frac{1}{2}\%$  removed by NaOH, thus utilizing the bleaching effect of NaOH and producing a min. amt. of foots.

P. ESCHER

**Heat consumption in the fatty acid industry.** K. E. SKÄRBLOM. *Arch. Wärme-wirt.* 10, 174-6(1929); cf. C. A. 23, 3116.—The results of a steam survey of a fatty acid plant using the Twitchell process and concg. glycerol are given. The latent heats, in cal./g., calcd. from the vapor pressure curves of others, are: for stearic acid, 166.3-0.38%, for palmitic acid, 152.8-0.35%; for oleic acid, 150.9-0.31%. ERNEST W. THIELE

**Bromine derivatives of linolenic acid.** WASABURO KIMURA. Kyoto Inst. for Chem. Res. *Chem. Umschau Fette, Oele, Wachse u. Harze.* 36, 125-8(1929).—The bromides were prepd. by adding an excess of Br to free linolenic acid at low temp., 145 g. bromides having been obtained from 300 g. On recrystn. from  $\text{C}_6\text{H}_6$  a white powder of tallowy feel resulted, m.  $183^\circ$ , neutralization no. 67.33, Br. 63.73%. The free linolenic acid being liberated from the hexabromostearic acid by means of Zn dust and MeOH plus HCl and the acid rebrominated with the calcd. amt. of Br yielded a cryst. hexabromostearic acid; an oily hexabromide resulted. No tetrabromide was observed, so that the presence of  $\beta$ -linolenic acid, which does not absorb Br quantitatively, could not be confirmed. When the bromination and debromination of the hexabromide were repeated, the yield of solid hexabromostearic acid as well as the Br content of the oily bromide and its I no. gradually diminished while the mol. wt. increased. These changes are evidently due to some oxidation of the linolenic acid and partly to polymerization. P. ESCHER

**Determination of iodine numbers. II. Action of iodine chloride solutions on the fatty acids with conjugated double bonds.** E. TH. GELBER AND J. BÖESEKEN. *Rec. trav. chim.* 48, 377-85(1929).—When Wijs' soln. is allowed to act upon linoleic acid dissolved in  $\text{CCl}_4$ , a low I no. is obtained unless a large excess of reagent is used (about 400% of the theoretical quantity) and about 48 hrs. allowed for the reaction to take place. By dissolving linoleic acid in  $\text{AcOH}$ , by adding Wijs' soln. and pipetting off portions at different intervals, it was found that the reaction takes place in 2 stages; the first stage takes place instantaneously and gives an I no. of about 91, corresponding to the effect of 1 double bond; the second stage corresponds to the action of I on the second double bond and takes place so slowly that low results are obtained if the analysis is conducted normally. The explanation seems to be that linoleic acid in contact with  $\text{ICl}$  takes up more Cl than I so that there is to a certain extent an accumulation of I in the reagent. In the case of eleostearic acid the formula proposed by Böesecken and Ravenswaay would call for an I no. of 270 whereas previous detns. have given 180; but in the light of the above facts, it is now possible to get as high a value as 272, so that the opinion is confirmed that eleostearic acid is a linoleic acid. Two double bonds react quickly but the third reacts very slowly with I. Apparently the first reaction with  $\text{ICl}$  results in the formation of a tetrachloride, which then very slowly adds on an additional mol. of  $\text{ICl}$ . W. T. H.

**Hardening oxidized oils.** W. NORMANN. *Chem. Umschau Fette, Oele, Wachse u. Harze* 36, 81-2(1929).—In technical hardening the OH group of castor oil is little or not at all attacked while its double C bond is fully satd., the hydroxyl no. usually dropping from 148 to 130-135. There are few or no OH groups in oxyns, the product of oxidized oils, but they react in part with  $\text{Ac}_2\text{O}$ . But the oxyns of fish oils are partly attacked in hardening with Ni at 180-190° before the double C bonds are satd.; higher temps. than 190° greatly influence the reaction and may explain the results of Wassiljero, who used high temps. and obtained different results. P. ESCHER

**Report of joint committee with A. S. T. M. on cold test of fatty oils.** R. R. MATTHEWS, et al. *J. Am. Leather Chem. Assoc.* 24, 242-4(1929). Pour point was detd on 2 samples of neatsfoot oil by the A. S. T. M. method (D97-28), employing (1) intervals of 5° F., as prescribed in the method, and (2) intervals of 2° F. between tests. By the latter procedure, the mean results for pour point found for the 2 oils were 2.2° F. and 0.9° F. lower than by the former, but the av. deviation of different analysts from the mean was no smaller when the test was made at smaller temp. intervals. For a low-test oil, the av. deviation from the mean was 2.1° F. and for a high-test oil, 1.6° F. Conclusion: The 2° F. interval in making the pour test has no particular advantage. H. B. M.

**Report of Smalley Foundation Committee. Coöperative meal samples for the season 1928-1929.** H. C. MOORE. *Oil & Fat Ind.* 6, No. 5, 24-7(1929).—Five tables are given showing the results of coöperative analytical work of the Smalley Foundation for oil and  $\text{NH}_3$ . E. SCHERUBEL

**Australian standard specifications for perilla oil and soy-bean oil.** *Australian Commonwealth Eng. Assoc.* (Sydney), Nos. K-12 and 13, 16 pp.(1929).—Standard methods of sampling and testing are included. E. I. S.

**Constituents of the soy bean with special reference to its oil sediment.** E. HOLTZ. *Seifensieder-Ztg.* 56, 103-4, 112-3, 121-2, 130-2, 140-1(1929).—An av. of 4 analyses of soy beans showed:  $\text{H}_2\text{O}$  13.88, fat 17.85, protein 37.87, crude fiber 6.30, ash 4.26, N-free ext. 1.30 and lecithin, 18.54; the last was calcd. from the percent of P, giving lecithin a mean mol. wt. of 800. The bean after the extn. of oil contains: protein 44.99, lecithin 18.00, oil 1.00,  $\text{H}_2\text{O}$  11.96, crude fiber 7.76, ash 6.62 and N-free ext. 9.65. After the extd. oil has been freed from its solvent, it deposits a sediment of phosphatides contg.  $\text{H}_2\text{O}$  20.20, free fatty acids 5.78, lecithin 48.67, dirt 4.07, unsapon. 1.08, protein 0.69 and neutral oil (difference) 17.51. From this sediment a fairly pure lecithin was prepd. by dissolving 100 g. in ether and pptg. with acetone; 45 g. of a light yellow, rapidly darkening, crumbly substance was obtained, which had all the properties of Merck's pure lecithin except that it flocculated in hot alc. and liberated some  $\text{H}_2\text{S}$ , while Merck's product was perfectly sol. P 3.89, N 1.22 and S 0.54% were found by analysis as against the calcd. 3.94, 1.75 and 0.0 for lecithin. Coagulation of the phosphatides by the elec. current failed, but addn. of electrolytes was successful, especially with  $\text{MgCl}_2$  and  $\text{MgSO}_4$  in 20-30% soln. Upon addn. of 0.5% of the soln. at 60° with intensive stirring, the phosphatides sepd. clean after 24-48 hrs. settling; the sediment showed 24.80-30%  $\text{H}_2\text{O}$ , 3.84-5.80 free acid, 0.98-1.99 unsapon., 43.64-53.48 phosphatides, 9.86-15.40 neutral oil and 3.00-6.22% dirt. To remove the Mg salts, the phosphatides were taken up in benzene, but the removal of the solvent caused the lecithin

to decomp. at 80°; it was necessary to add 25% oil during this distn. to protect the lecithin. The sepn. of the phosphatides from the oil by heat resembles the coagulation of albumin, a transformation of a colloidal soln. into a suspension. The solvent can be removed by adding some 40% coconut oil and distg. in a CO<sub>2</sub> atm. without decomp. the phosphatides. When the oil is extd. from the bean by benzene, phytosterol is also extd. and accumulates in the soap stock up to 2–3%. It may be sepd. by treating the soap stock with acid, neutralizing the sepd. acids, extg. the resulting soap with benzene, evapg. the solvent, and crystg. residual phytosterol from alc. P. ESCHER

**Domestic soy-bean oil.** OTTO EISENSCHIML. *Oil & Fat Ind.* 6, No. 4, 15–20 (1929).—This is a survey of the history and prospects of development of soy-bean oil in the U. S. E. SCHERUBEL

**American safflower-seed oil.** GEORGE S. JAMIESON AND SAMUEL I. GERTLER. *Oil & Fat Ind.* 6, No. 4, 11–3 (1929).—The consts. of a sample of hot-pressed oil from seed grown in Montana were  $d_{25}^{20}$  0.9243,  $n_{25}^{20}$  1.4744, I no. 149.3, sapon. no. 190.5, acetyl no. 12.5, R. M. no. 0.2, Polenske no. 0.1, % hexabromide 0.4, unsapon. 0.59%, satd. acids 5.93, unsatd. acids 87.72%, I no. of unsatd. acids 156. The compn. of the oil in % of acids was: oleic 25.7, linolic 65.8, linolenic 0.15, myristic 0.04, palmitic 4.1, stearic 1.6, arachidic 0.4, lignoceric 0.06. E. SCHERUBEL

**Official cottonseed analysis.** LEHMAN JOHNSON. *Oil & Fat Ind.* 6, No. 4, 35–6 (1929).—Crack the seed, without grinding or sepg., in a mortar. Weigh out 10 g. and dry 4 hrs. at 102–3° for detn. of H<sub>2</sub>O. Immediately grind in an iron mortar after adding 2.5 g. of ground glass. Place the whole in filter papers, using a Butt tube and a 50-cc. extn. flask having a file mark on the neck showing 60 cc. when filled to this mark. Add 30 cc. of standard petroleum ether and ext. 4 hrs. without regrinding. Without evapg. the ether, fill with more ether and mix thoroughly. Remove and set aside 30 cc. for the free fatty acid test. Evap. the ether from the half portion and weigh for oil. Remove the entire residue from the filter into an 800-cc. Kjeldahl flask marked on the neck to show when filled to 900 cc. Add 1 g. HgO, 15 g. K<sub>2</sub>SO<sub>4</sub> and 50 cc. H<sub>2</sub>SO<sub>4</sub> and digest in the usual way. Fill with H<sub>2</sub>O to the 900-cc. mark and pour off 600 cc. for duplicate detns. Add the usual reagents and distill the NH<sub>3</sub>. To the 30 cc. petroleum-ether soln. of oil add 15 cc. neutral alc. and 0.5 cc. 1% phenolphthalein soln.; titrate with 0.1 N alkali. The wt. of the oil is known from the other half evapg. off for oil. Calc. the free fatty acid. E. SCHERUBEL

**Thiocyanate value of parsley-seed oil.** A. STEGER AND J. VAN LOON. Tech. Hochschule, Delft. *Z. Untersuch. Lebensm.* 56, 365–7 (1928).—Kaufmann's method (C. A. 20, 2256) is used for detg. the thiocyanate value of linolic and satd. acids in parsley-seed oil. The compn. is unsapond. matter 30, total fatty acid 65.2 (consisting of satd. acid 3.0, petroselinic acid 45, 9,10-oleic acid 8.0, linolic acid 9.1), glycerol residue 2.8, volatile matter 2.0%. Twitchell's (C. A. 15, 3617) Pb salt and alc. method cannot be used for sepg. the fatty acids of this oil, because the Pb salt of petroselinic acid is fairly fusol in EtOH. Bertram's oxidation method proved inapplicable. F. P. G.

**The composition of rape oil of German origin.** K. TAUFEL AND C. L. BAUSCHINGER. Deut. Forschungsanstalt Lebensmittelchemie Munich. *Z. Untersuch. Lebensm.* 56, 253–64 (1928); cf. C. A. 23, 294. Rapeseed extd. under pressure yielded 21% oil. This was filtered at 40° and refined by treatment with H<sub>2</sub>SO<sub>4</sub>. Two years storage did not alter the properties of the oil. A table of properties is given. The satd. fatty acids were pptd. from the oil by addn. of excess Pb(OAc)<sub>2</sub> soln. according to the method of Twitchell (C. A. 15, 3617) and the ppt. was filtered off after 12 hrs. at 15°, washed with EtOH and recrystd. from Et<sub>2</sub>O. The fatty acids obtained were dissolved in EtOH and fractionally pptd. 6 times with 1% LiOAc in 95% EtOH. The pptd. contained 18.85% satd. fatty acid and 81.15% erucic acid. The filtrate from the Twitchell sepn. was treated with EtOH soln. of Mg(OAc)<sub>2</sub> and erucic acid liberated from the Mg salt and recrystd. from EtOH. The mother liquor was brominated at –14° for 3 hrs. and the bromide filtered off, washed with Et<sub>2</sub>O and weighed. The  $\alpha$ -hexabromostearic acid (m. 179°) obtained corresponded to 2.45% linolenic acid. The residue left by evapg. the brominated mother liquor was warmed at 35° with petroleum ether for 20 mins. and  $\alpha$ -tetrabromostearic acid (m. 114°) equal to 5.42%  $\alpha$ -linolic acid was obtained. The oleic acid was detd. by pptg. an EtOH soln. of the fatty acids with Zn(OAc)<sub>2</sub>. The % compn. of the oil was: erucic acid 43.5, oleic acid 37.8, linolic acid 10.6, linolenic acid 3.5, glycerol residue (C<sub>3</sub>H<sub>5</sub>) 3.8, unsaponifiable matter 1.0% and satd. fatty acid 0.8%. FRANCIS P. GRIFFITHS

**Glycerides of rape oil.** K. TAUFEL AND C. L. BAUSCHINGER. *Z. Untersuch. Lebensm.* 56, 265–72 (1928).—The presence of oleo-linolenic-erucin, oleo-dierucin, and trierucin in rape oil has been established (C. A. 15, 606). The amts. of oleo-dierucin and tri-

erucin are uncertain and cannot be detd. from the erucic acid content, on account of the presence of other mixed glycerides contg. this acid. Mol. wt. and Br. detn. on products resulting from fractional crystn. of brominated glycerides indicated 1.7% of oleolinoleno-erucin, corresponding with 0.5% linolenic acid. The remainder is combined in a different form. Fractional crystn. from a mixt. of rape oil and  $\text{CH}_3\text{COCH}_3$  at 20° and 0° by the method of Tomow, *viz.*, the action of  $\text{N}_2\text{O}$  on the mixt., gave *elaidodibrassinidin*  $[\text{C}_{21}\text{H}_{41}(\text{C}_{22}\text{H}_{43}\text{O}_2)_2 (\text{C}_{19}\text{H}_{39}\text{O}_2)]$  and *tribrassinidin*  $\text{C}_{21}\text{H}_{41}(\text{C}_{22}\text{H}_{43}\text{O}_2)_3$ . F. P. G.

Oil of *Cydonia vulgaris*. E. BUREŠ AND J. ŠÁTEK. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 187-8(1928).—The oil extd. with ether from the ground seeds of *Cydonia vulgaris* in 20.50% yield had constants as follows: d. 0.919, acid no. 7.82, sapon. no. 186.0, I no. 107.60, Reichert-Meissl no. 2.046, Polenske no. 0.467, Ac no. 23.58. WILLIAM J. HUSA

Oil of *Nigella sativa*. E. BUREŠ AND H. MLÁDKOVÁ. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 186-7(1928).—The oil extd. with ether from the seeds of *Nigella sativa* in 30% yield had consts. as follows: d. 0.8930, acid no. 14.68, sapon no. 210.60, I no. 110.9, Reichert-Meissl no. 3.378, Polenske no. 0.532, Hehner no. 89.22, Ac no. 23.92. WILLIAM J. HUSA

Oil of peony. E. BUREŠ AND B. ŠUSTEROVÁ. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 185-6(1928).—The oil extd. with  $\text{CCl}_4$  from the ground seeds of the peony (*Paeonia peregrina*) in 22.15% yield had consts. as follows: d. 0.9600, acid no. 14.01, sapon. no. 211.26, I no. 187.10, Reichert-Meissl no. 1.537, Polenske no. 0.5568, Hehner no. 91.87, Ac no. 12.96. WILLIAM J. HUSA

Oil of *Hyoscyamus niger*. E. BUREŠ AND A. KRACÍK. Charles' Univ., Prague. *Časopis Českoslov. Lékárnictva* 8, 183-5(1928).—The oil extd. with petr. ether from the ground seeds of *Hyoscyamus niger* in 30.25% yield had consts. as follows: d. 0.921, acid no. 23.60, sapon. no. 187.70, I no. 135.70, Reichert-Meissl no. 1.055, Polenske no. 0.452, Hehner no. 93.34, Ac no. (Normann) 21-21.6, Ac no. (Lewkowsitch) 20.54. W. J. H

Chemical study of the liver oil of a young male basking-shark, *Cetorhinus maximus* Günner. Biological relations between cholesterol and squalene. ÉMILE ANDRÉ AND HENRI CANAL. Hospice de la Salpêtrière, Paris. *Ann. combustibles liquides* 3, 833-50 (1928); cf. C. A. 21, 1891.—A study which compares the liver oil of a young shark with that of the adult animal shows that the transformations: fatty acid→cholesterol→squalene take place during the growth of the animal. The liver oil of the young shark contains 58.5% by wt. of fatty acids (of the approx. compn. by wt.: myristic,  $\text{C}_{14}\text{H}_{28}\text{O}_2$ , 20%; therapeutic,  $\text{C}_{18}\text{H}_{36}\text{O}_2$ , 10%; arachidonic,  $\text{C}_{20}\text{H}_{40}\text{O}_2$ , 15%; and cetoleic,  $\text{C}_{22}\text{H}_{42}\text{O}_2$ , 55%), 32% of which was in the form of glycerides and the remainder as esters of cholesterol. The unsapond. material consisted of squalene,  $\text{C}_{30}\text{H}_{50}$  (mixed with small quantities of pristane,  $\text{C}_{19}\text{H}_{38}$ ); and cholesterol,  $\text{C}_{27}\text{H}_{46}\text{O}$ , in amts. representing, resp., 18 and 22.5% by wt. of the original liver oil. R. E. SCHAAD

Calibration of sixty-five 35-yellow Lovibond glasses. I. G. PRIEST, D. B. JUDD, K. S. GIBSON AND G. K. WALKER. *Bur. Standards J. Research* 2, 793-819 (1929); cf. C. A. 22, 4265.—Sixty-five 35-yellow Lovibond glasses were calibrated and considered fit to be regarded as equiv. to standard 35-yellow under the present customary conditions of grading oils. The discrepancies of color grading cannot be charged to lack of uniformity among the 35-yellow glasses. The sources of these troubles are: (a) unstandardized, non-uniform and insensitive methods of comparing the oil samples with the glasses, (b) grading of oil by observers having abnormal color sense or low power of hue discrimination, (c) errors in the red glasses. E. SCHOTTE

Report of soap section committee. Progress achieved in formulation of standards for acids used in glycerol analysis. A. K. CHURCH. *Oil & Fat Ind.* 6, No. 5, 28-33 (1929).—The report of 11 lbs. is given on the precise method of standardizing the acid used. The use of one indicator does not give the same results as the use of another indicator. Six labs. use  $\text{Na}_2\text{CO}_3$ , 4 use  $\text{AgCl}$ , and 1 uses benzoic acid. E. SCHERUBEL

Common antiseptics used in soaps. PAUL I. SMITH. *Am. Perfumer* 24, No. 2, Soap Ind. Sec., 147-8(1929).—The antiseptics which find favor for use in soap are coal tar, phenolic and cresolic preps., mercuric chloride and iodide, essential oils such as resins, terpine, almond oil and thymol. Before a chemical can affect a micro-organism it must first penetrate the lipid covering and the thickness of this varies with different organisms, and therefore the rate of absorption of the antiseptic is in simple ratio to this factor. The remedial value of phenolic soaps is questionable, but the Hg soaps are very useful in skin diseases. Hg salts have no injurious effects on the soap. Many of the heavy metallic salts are of doubtful value in soaps because of this pptg. action on proteins. Essential oils possess antiseptic properties and highly scented

soaps are of greater value than the pungent medicinal soaps so widely advertised.

**The metal soap content of fats and the examination of metallic soaps.** H. DUBOVITZ. *Chem. Umschau Fette, Oele, Wachse u. Harze* 36, 160-2(1929).—A description of the methods used in detg. Ca soaps in bone grease and the detn. of free fatty acids in Zn oleate. P. ESCHER

**Check on the salt-rubin method.** J. HERRTES. *Z. phys. chem. Seifenforsch.* 2, 22 5(1929); cf. Zakarias, *C. A.* 23, 2056.—For comparative results in detg. the salt-rubin no. of soaps it is necessary to standardize the Congo rubin indicator so that 10 cc. of a 0.01% soln. turns violet only after addn. of 0.5 cc. of a 10% NaCl soln. Some test results with different soaps and indicators are tabulated. "Grübler" Congo rubin is preferred. P. ESCHER

**Remarks about the methods of analysis for soaps and soap powders.** J. GROSSER. *Seifensieder-Ztg.* 56, 127-9(1929).—G. suggests for the detn. of total fatty acids, as proposed by the Commission for Standard Methods of Analysis, to decomp. the warm soap soln. directly in a separatory funnel instead of in a beaker with subsequent transfer to the separatory funnel. While the Commission omits the washing with H<sub>2</sub>O of the ether soln. of fatty acids, G. recommends it, especially when H<sub>2</sub>SO<sub>4</sub> has been used, but thinks the drying with anhyd. Na<sub>2</sub>SO<sub>4</sub> unnecessary when the layers form clear solns. Any H<sub>2</sub>O that enters the ether by washing is carried off with the ether at 50° if brisk evapn. is maintained. Unsapon. neutral fat and unsapon. matter: The proposed washing of the united petr. ether ext. with 50% alc. contg. some NaOH is wrong in principle, since a 50% alc. soap soln. can saponify small quantities of neutral fat in the presence of free alkali; it is better to add a little soda to the alc. The drying of the unsapon. at 100° until all odor of petroleum ether has disappeared may cause some loss if hydrocarbons are present; drying at 80° to 90° is recommended. Geissler's app. for CO<sub>2</sub> detn. yields unreliable results, and the regular absorption train is recommended. In detg. Na silicate the concn. of soap soln. and HCl should be definitely stated to avoid incomplete pptn. of SiO<sub>2</sub>. The mean mol. wt. of fatty acids in the detn. of Na<sub>2</sub>CO<sub>3</sub> in soap powders should be lowered from the proposed 300. In the detn. of the turbidity point the hot filtrate should be readjusted to its original wt. by addn. of H<sub>2</sub>O. P. ESCHER

**Washing extracts and their preparation.** R. KRINGS. *Seifensieder-Ztg.* 56, 137 9(1929).—"Washing exts." are K soaps contg. some solvent like hexalin, etc., and are used mostly in the textile industry for special purposes. P. ESCHER

**Experiments to prepare highly active washing extracts.** R. KRINGS. *Seifensieder-Ztg.* 56, 158-9(1929).—K. describes the prepn. of liquid K soaps of extraordinary cleansing power and of a cream-like appearance by adding 2 1/2% of oil of turpentine in one case and 2 1/2% NH<sub>4</sub>Cl in another case. P. ESCHER

**Arsenical soaps.** ARNOLD N. MACNICOL. U. S. 1,711,503, May 7. In forming arsenical soaps suitable for *insecticidal purposes*, wool fat is mixed with caustic alkali and an alkali arsenite and the resulting mixt. is emulsified (suitably by heating to about 90–105°).

## 28—SUGAR, STARCH AND GUMS

J. K. DALE

**Determination of chlorine in sugar-factory products.** C. E. BUDLOVSKÝ. *Z. Zuckerind. Tschoslovak. Rep.* 52, 421–30(1928).—In the case of products sol. in water or dil.  $\text{HNO}_3$ , the acidified soln. is treated with a slight excess of  $\text{AgNO}_3$ , clarified with  $\text{FePO}_4$ , and the ppt. centrifuged and dried without washing. It is then distd. with concd.  $\text{H}_2\text{SO}_4$  in the presence of Cu in a special app., the HCl condensed in water being titrated by Votoček's method. Insol. products are distd. with concd.  $\text{H}_2\text{SO}_4$  in the same app., following the lines of the Vaubel-Scheuer method (*Chem.-Ztg.* 30, 167 8 (1906), and the HCl is detd. as before. Results obtained by these 2 methods were consistently higher than those found by detg. the Cl in the ash of the product examd.  
B. C. A

**Chlorine as a sugar decolorant.** L. R. BLISS. *Sugar* 31, 3–5, 57–9, 99–101(1929).—Chlorine gas, washed and dried, was led into the solns. to be decolorized. Its effect upon the polarization of sucrose, dextrose, invert sugar and mixts. of these was practically nil. Diluted molasses defecated with Horne's dry lead followed by treatment with Cl gave solns. easily polarized. Addn. of K alum or  $\text{AlCl}_3$  to cloudy solns. resulting from chlorination of leaded filtrates causes flocculation and easy filtration. The use of a defecant is necessary with cane juice and molasses. Directions for the use of Cl in the Clerget detn. are essentially as follows: Transfer 2.5 normal sugar wts. of molasses or other product with a little  $\text{H}_2\text{O}$  to a 250-cc. flask. Add basic Pb acetate and alumina cream and complete the vol. Shake, filter and delead with a little powd.  $\text{K}_2\text{C}_2\text{O}_4$ , add kieselguhr and filter. Treat 50 cc. of the filtrate in a 100-cc. flask with 30 cc. satd. Cl water and allow to stand in a cool place to bleach. Dil. to vol. and read. To a second 50 cc. add 30 cc. of a soln. of HCl in satd. Cl water adjusted to 1.1 sp. gr. and let stand 2–3 hrs. Adjust to vol. and polarize. Correct the direct and invert readings for concn. and for the sucrose. Calc. Clerget by the usual formula using the Steuerwald factors. The possibilities of dangers by inversion in the direct polarization, of the oxidation of levulose, and of the influence of HCl upon the specific rotation of levulose are discussed. Tables are given in which comparison is made between results obtained with and without the use of Cl in both direct polarization and Clerget methods. A tentative method is given for the "approx." detn. of purity by destruction of reducing sugars with alkali followed by Cl bleaching and polarization. The Brix is detd. preferably by refractometer.

**Sodium hyposulfite in the sugar factory.** MARCEL LEMIRE. *Bull. assoc. chim. suc. dist.* 46, 33–5, 68–70(1929).—The merits and defects of the various preps of sulfur compds. used in sugar factories are discussed. Full details as to technical use are given. Methods of analyzing the sulfur compds. are described.  
E. A. FIEGU

**Determination of end point in the final saturation.** O. SPENGLER and C. BRENNEL. *Z. Ver. deut. Zuckerind.* 79, 39–43(1929).—The present methods of detg. the end point of the carbonation process are reviewed. The difficulties inherent in these methods are mentioned. A new method is given: Approx. 25 cc. of juice without filtration is poured into a small stand glass. Five drops of phenolphthalein soln. is added to the hot sample, followed by 5 drops of  $\text{CaCl}_2$  soln. (15 g. to 100 cc.). About half a min. after shaking the container, the color of the soln. is noted. If it is a faint, dirty rose,

then satn. is complete; if colorless, the  $\text{CO}_2$  supply must be cut off; if it is a distinct rose or red color, carbonation must be continued. This method is more readily carried out than the customary titration.

E. A. FIEGU

**The most advantageous method of thin juice sulfitation.** ERNST THIELEPAPE AND PAUL MEIER. *Z. Ver. deut. Zuckerind.* 79, 176-93(1929).—The authors point out the defects of the Weisberg process. Two methods of sulfitation are given: (1) introducing  $\text{SO}_2$  into the filtered juice from the second carbonation, till slightly acid, and then adding  $\text{Na}_2\text{CO}_3$  to an alkalinity of about 0.02; (2) an alkaline process in which about 0.14% (on beets)  $\text{Na}_2\text{CO}_3$  is added to the filtered juice prior to the second carbonation, and carbonation continued to about 0.05 alky., followed by sulfitation till the alky. reaches about 0.02. These two processes, in comparison with the old process, give juices which are very low in lime salts, and which have a light color. Again, the  $\text{SO}_2$  stays in the juice as alkali sulfite, and is fully utilized. Full details of all exptl. work are given, and comparative tables are supplied. Sirups from poor beets high in lime salts when sulfitated and then treated with  $\text{Na}_2\text{CO}_3$ , can be largely freed from Ca.

F. CAMPS-CAMPINS

**The sugar content of carbonation press cake.** A further contribution to the explanation of undetermined losses. O. SPENGLER AND C. BRENDL. *Z. Ver. deut. Zuckerind.* 79, 61-76(1929).—The customary methods of detg. sugar in press cake do not give true values. Microscopic examn. of press cake showed particles of slime from which sugar is removed with difficulty. Detns. of the true sugar content of samples gave values which were 2 to 2.5 times that given by the regular method of analysis. Fresh press cake was analyzed by the usual method; also a quantity of press cake was digested at 95-99° for about  $\frac{3}{4}$  hour with stirring, filtered and the sugar content of the filtrate and of the sludge detd., giving the true sugar content of the press cake. The work was checked by concn. of the filtrate. The digestion permitted the extn. of the sugar from the slime particles. A sweetened-off press cake will, on standing, give a higher sugar content than if analyzed when fresh. This is due to the sugar diffusing from the interior of the slime particles in the course of time.

E. A. FIEGU

**Automatic apparatus for determination alkalinity of continuous carbonation.** P. R. CHECHEL AND M. G. LISHCHINSKII. *Nauch Zapiski Sakharnoi Prom.* 7, 24-6(1928). The app. is described.

V. E. BAIKOV

**The "De Vecchis" process.** Comparison of French and Italian beets. P. MARCINELLI. *Bull. assoc. chim. suc. dist.* 46, 133-9(1929).—Because of differences in compn. of French and Italian beets, results of the Vecchi process in Italy should be compared only to Italian factory figures for the ordinary process and not to such figures from other countries. Results show that the process is satisfactory.

F. C.-C.

**New experiments on beet saponins.** K. REHORST. *Z. Ver. deut. Zuckerind.* 79, 155-75(1929).—Previous work is reviewed. From a thorough study of its cleavage products, the author assigns the formula  $\text{C}_{37}\text{H}_{56}\text{O}_9$  to sugar beet saponin: this is checked by elementary analysis. The results of titration point to 2 free carboxyl groups. The hydrolysis of saponin is then expressed by the equation:  $\text{C}_{37}\text{H}_{56}\text{O}_9 + \text{H}_2\text{O} = \text{C}_{31}\text{H}_{48}\text{O}_3 + \text{C}_6\text{H}_{10}\text{O}_7$ . (Sugar beet saponin plus  $\text{H}_2\text{O}$  gives beet sapogenin and *d*-glucuronic acid.) Within the limits of exptl. error, these cleavage products can be shown to occur in the amts. required by the equation. The methods of prepn., and the properties of these substances are studied experimentally so as to throw light on their structure. Full description of all expts. is included.

F. CAMPS-CAMPINS

**The precipitation of colloids from beet-sugar molasses.** I. ERICH GUNDERMANN. *Chem.-Ztg.* 53, 305-7(1929).—Solns. of beet sugar molasses contg. 10-50% dry substance were treated with increasing amts. of acid. The time required for flocculation to become visible was observed in each case. At a  $p_H$  of about 3.2 flocculation occurs most rapidly, while at a higher as well as a lower value the velocity decreases. At 80° sedimentation was much faster with formation of rapidly settling clusters. For detn. a lower temp. must be used, as otherwise decompn. products are formed. In dil. soln. more colloids are coagulated than in concd. soln. II. *Ibid* 322-3.—Clarification, ease of filtration and decolorization of solutions, accompanying flocculation, is optimum at  $p_H$  3.2. The best results in clarification and purification of juices and sirups in sugar houses with  $\text{SO}_2$ , are obtained at  $p_H$  close to that producing inversion. J. C. J.

**Composition and digestibility of maize and the by-products from its treatment for technical purposes [corn starch] (HONCAMP, et al.) 12.** Action of  $\text{SiO}_2$ ,  $\text{Al}_2\text{O}_3$ , and kaolin on  $\text{BaSO}_4$  (MARCHAL) 6. Apparatus for reduction of mannose, glucose and other sugars (U. S. pat. 1,712,952) 4. Electrolytic cell for reducing mannose to mannitol

or for other reductions of sugars, etc. (U. S. pat. 1,712,951) 4. Cellulose [from bagasse] (Fr. pat. 650,194) 23. Vinasses (Fr. pat. 650,804) 15.

EARLE, FRANKLIN S.: *Sugar Cane and Its Culture*. New York: John Wiley & Sons, Inc. 355 pp. \$4.50.

TALWAR, OM P.: *Remedy of Unknown Losses in the Sugar Industry*. Chakwal, Jhelum, Punjab, India: Talwar Chemi Cottage. 27 pp. Rs. 1. Reviewed in *Intern Sugar J.* 31, 217 (1929).

**Sugar.** JACOB POHLMANN and JACOBUS R. F. RASSERS. Fr. 650,844, Mar. 14, 1928. Albumins are eliminated from sugar juices coming from the presses by the addn. of tannic acid or its derivs., MeOH, picric acid, phosphotungstic acid or phosphomolybdic acid. Crystn. of the sugar is thereby greatly facilitated.

**Treating sugar solutions to increase their sucrose content.** WALTER H. DICKERSON (to Industrial Waste Products Corp.). U. S. 1,713,118, May 14. A sugar soln. which contains both sucrose and invert sugar is treated to obtain a product in powder form and of greater proportionate sucrose content than the original sucrose content of the soln., by spraying the soln. into a hot drying gas and effecting a reduction in the temp. of the sprayed material by the time drying is substantially completed so that the product is not injured.

**Sugar juice.** AKTIEBOLAGET SEPARATOR. Fr. 650,752, Mar. 12, 1928. After the addn. of lime to ppt. the impurities, sugar juice is decanted by gravity so that only a small amt. of solid substances remains in it, which are extd. by a centrifuge provided with a bowl having non-perforated walls on which the solid substances deposit and from which they are periodically removed.

**Sugar juice.** AKTIEBOLAGET SEPARATOR. Fr. 651,113, Mar. 22, 1928. Sugar juice is purified by adding lime and centrifuging before pptg. excess of lime, *e. g.*, by the addn. of CO<sub>2</sub>. Substances of less sp. gr. than the juice are eliminated before the addn. of lime.

**Products from molasses.** YOSITARO TAKAYAMA. Fr. 650,994, Mar. 19, 1928. Betaine-HCl and KCl are extd. from waste molasses by passing in HCl to the concd. liquor whereby KCl is pptd. The liquor is filtered and concd. whereby betaine HCl contg. some KCl is pptd. The ppt. is dissolved in water, neutralized with CaCO<sub>3</sub>, filtered and concd. whereby crystals of KCl are obtained. HCl is added to the filtrate from these, and concn. gives betaine-HCl. After filtering the filtrate may be used as a starting point for the prepn. of glutamic acid.

## 29—LEATHER AND GLUE

ALLEN ROGERS

**Temperature factor in vegetable tannin fixation.** ARTHUR W. THOMAS AND MARGARET W. KELLY. Columbia Univ. *J. Am. Leather Chem. Assoc.* 24, 282-9 (1929).—Two-g. portions of fat-free hide powder were tanned with solns. contg. 40 g. solids per 1000 cc. of 1 of the following exts.: wattle, oak bark, gambier or quebracho. Temps. employed were 4°, 7°, 25° and 37.5°. After varying periods, up to 117 days, each sample was washed free from sol. matter in a Wilson-Kern extractor, dried and weighed, increase in wt. being taken as tannin fixed. Rate of tannage increased rapidly with temp., and increase in rate is much greater for the 12.5° interval from 25° to 37.5° than for the 18° interval from 7° to 25°. Tanning takes place at the lowest temp. tried.

H. B. MERRILL.  
**Determination of moisture in tanning extracts.** Committee report, 1928-29. HENRY B. MERRILL, *et al.* *J. Am. Leather Chem. Assoc.* 24, 314-20 (1929).—Direct drying of a weighed sample of solid quebracho ext. was compared with evapn. and drying of an aliquot of the analytical soln. Some members of the committee obtained identical results by the 2 methods, both of which are now official, other members obtained more H<sub>2</sub>O by direct drying, probably because of gain in wt. of residues from evapn. of soln., due to oxidation. **Recommendation.**—The direct drying method should be employed only when the ext. does not give uniformly turbid soln. H. B. MERRILL.

**Determination of insoluble matter in tannin extracts.** D. McCANDLISH AND W. R. ATKIN. Leeds Univ. *J. Am. Leather Chem. Assoc.* 24, 231-5 (1929).—The analytical soln. is filtered through paper, with the aid of kaolin, as in the official method, but a Büchner funnel and suction are employed. The app. consists of a Büchner funnel,

preferably with stopcock in stem, connected to a straight-sided separatory funnel with side tube and stopcock, which connects to a filter flask. Vacuum is applied both to the flask and to the funnel. The paper is tanned 1 hr. as usual, the filtrate being collected in the funnel, and transferred to the flask periodically until it comes through optically clear. After tanning the paper, fresh soln. is poured on the filter, the soln. in the receiving funnel is drawn into the flask, and then the vol. of filtrate required for evapn. is collected in the funnel. Insol. matter in 6 different exts. was detd. by the above and by the filter candle method. No difference beyond the limit of exptl. error was found with liquid and solid chesnut, quebracho, mimosa and a blended ext. With liquid myrobalams (2 samples), the paper method gave 0.7 and 0.9% more insol. matter than the candle; with the latter, an optically clear filtrate could not be obtained. Advantages claimed for the proposed method over the official procedure are (1) more uniform thickness of kaolin layer on the paper, and (2) smaller error due to tannin adsorption by the paper because of the smaller paper employed. As compared to the candle method, the filtration is slower but time spent in cleaning candles is saved.

H. B. MERRILL

**Determination of insoluble matter in tannin extracts.** C. RISS. Tech. Hochschule, Darmstadt. *J. Am. Leather Chem. Assoc.* 24, 229-31(1929); cf. preceding abstract.—The method proposed by McCandlish and Atkin is simplified by filtering under the suction produced by a column of filtrate in a capillary tube 1.2 m. long. No special app. is required.

H. B. MERRILL

**The one-bath chrome tanning process in the light of Werner's coordination theory.** C. H. SPIERS. *Leather Trades Rev.* 51, 891, 964(1928); 52, 14, 96(1929); *J. Am. Leather Chem. Assoc.* 24, 246-70(1929).—The work of Gustavson, Stiasny and others is reviewed. Conclusion: The quality of a Cr leather appears to depend upon the nature of the acido-chromi-complex that it contains, its acidity, and the nature of the acid radical.

H. B. MERRILL

**Action of water on vegetable-tanned leather. I. Rate of removal of uncombined water-soluble matter.** HENRY B. MERRILL. A. F. Gallun and Sons Co., Milwaukee, Wis. *J. Am. Leather Chem. Assoc.* 24, 235-42(1929).—Vegetable-tanned leather contains substances that are firmly combined, loosely combined and not combined at all with collagen. It is shown that such uncombined substances as glucose, NaCl and Na gallate are completely removed by washing in a percolator for 2 hrs. or less. A sample of vegetable-tanned leather contg. no added load lost about 5% org. H<sub>2</sub>O-sol. matter in the same time, and the "% H<sub>2</sub>O-sol. matter: time-of-washing" curve for this leather had no break up to 4 days. This shows that it is not possible to distinguish between added, sol. loading materials and org. H<sub>2</sub>O-sol. matter naturally present, on the basis of ease of extrn. from the leather with H<sub>2</sub>O.

H. B. MERRILL

**Tentative Australian standard specifications for vegetable-tanned leather belting.** *Australian Commonwealth Eng. Standards Assoc.* (Sydney) No. B4, 15 pp.(1929).—Specifications cover quality of leather, currying, manuf., length of lap, thickness of grades and tests.

E. I. S.

**How temperature and humidity affect leather belts.** D. A. HAMPSON. *Power Transmission* 34, no. 3, 21-2(1929).

E. I. S.

**Critical study of the biochemistry of soaking and liming. III. Influence of the gaseous environment upon the soaking of heavy hides.** E. R. THEIS AND JEROME M. MILLER. Lehigh Univ. *J. Am. Leather Chem. Assoc.* 24, 290-314(1929).—Samples of 50 g. of either domestic or South American hides cut into pieces about 1 cu. mm. were suspended in 250 cc. of water at 25° for 14 days. A continuous current of 1 of the following gases was passed through the app.: O<sub>2</sub>, N<sub>2</sub>, H<sub>2</sub>, CO<sub>2</sub>, air, C<sub>2</sub>H<sub>2</sub>, SO<sub>2</sub> or producer gas. At the end of the expt. the solns. were examd. for acidity, total amide N, total dissolved N, total protein N, formol titration, dissolved S and dissolved volatile acids. With domestic hides, the least putrefaction occurred in the presence of C<sub>2</sub>H<sub>2</sub>, SO<sub>2</sub> and CO<sub>2</sub>; most decompn. occurred in the presence of H<sub>2</sub> and N<sub>2</sub>. With South American hides, air and H<sub>2</sub> caused the most, and N<sub>2</sub> the least, decompn. In the presence of CO<sub>2</sub>, notable amts. of S compds. from epidermis and hair were rendered sol. Butyric acid was formed in all liquors—least in the presence of air or O<sub>2</sub>, most in the presence of H<sub>2</sub> and N<sub>2</sub>. Hydration of skin was studied as a function of gaseous environment by the method of Theis and Neville (*C. A.* 23, 2319). Hydration was greatest in the presence of CO<sub>2</sub> and O<sub>2</sub>, and least in the presence of N<sub>2</sub>.

H. B. MERRILL

**Hydrolysis of hide powder in saturated sodium chloride solutions at various *p*<sub>H</sub> values.** ARTHUR W. THOMAS AND MARGARET W. KELLY. Columbia Univ. *J. Am. Leather Chem. Assoc.* 24, 280-2(1929).—Samples of hide powder were suspended in solns. of initial *p*<sub>H</sub> values from 0.76 to 9.97, all satd. with NaCl. Aliquots were removed

and filtered, and dissolved N was detd. after various periods up to 224 days. Percent of the total collagen present that was dissolved in 224 days increased with the  $p_H$  value of the soln., being approx. 3 times as great as  $p_H$  9.97 (8.36 final) as at  $p_H$  0.76 (4.49 final). Use of  $Na_2CO_3$  in salt used for curing is therefore inadvisable. H. B. MERRILL

**Analysis of some English book-binding leathers.** R. W. FREY, L. R. LEINBACH AND E. O. REED. Bur. Chem., Dept. Agr. *J. Am. Leather Chem. Assoc.* **24**, 190-6 (1929).—Analyses and tensile-strength measurements were made on 13 goat, 6 calf, 1 cow and 1 pig leather, all submitted as especially suitable for book-binding. Thirteen of these leathers were claimed, and found to be practically free from  $H_2SO_4$  (Proctor Searle Method). The others contained from 0.0 to 2.2%  $H_2SO_4$ . In general, the leathers contg. the most acid had the lowest tensile strength.  $p_H$  values of aq. exts. of all leathers were detd. In all cases where %  $H_2SO_4$  < 0.5, the  $p_H$  value of the ext. < 3.0; in 4 out of 5 leathers in which  $H_2SO_4$  > 0.5%, the  $p_H$  value of the ext. < 3.0. The authors consider most of these leathers to be over-tanned and deficient in grease. Pyrogallol tannage was found in 16 cases, and mixed tannage in 6 cases. The life of bindings made from these leathers is being detd. H. B. MERRILL

Causes and prevention of deterioration in book materials (WALTON) **23**. A modified Wilson-Kern extractor (MERRILL) **1**. Analysis of  $Na_2S$  (PAESSLER) **7**. 2,4-Diaminodiphenylamine as an ursol dye (KARPUKHIN) **25**. Fertilizers [from tannery waste] (Fr. pat. 647,376) **15**. GRASSER, GEORG.: *Einführung in die Gerbereiwissenschaft*. Leitf. f. Studierende u. Praktiker. Leipzig: Paul Schulze. 173 pp. M. 12.

**Depilating hides and skins.** MAX BERGMANN, EUGEN IMMENDÖRFER and HERMANN LOEWE (Fritz Stather, inventor). Ger. 475,301, July 3, 1924. Addn. to 434,569. According to Ger. 434,569, hides and skins are depilated by suitable alkali depilating agents in the presence of sol. silicates. This method is now modified by using  $(NH_4)_2S$  and (or) other  $NH_4$  salts in place of the alkali depilating agents.

**Textile fibers from shark skins, etc.** ALFRED EHRENREICH. U. S. 1,713,036, May 14. See Fr. 647,030 (C. A. **23**, 2598).

**Leather.** JEAN MULSANT. Fr. 650,357, Feb. 20, 1928. Cracks and faults in leather are removed by a mixt. contg.  $Sb_2S_3$  5, black stearate 10, lamp black 20, nitrocellulose 39, amyl acetate 35%.

**Artificial leather.** FRANÇOIS M. LOUP. Fr. 650,593, Mar. 8, 1928. Waste and old leather is washed with a warm soln. of  $NaHCO_3$  and  $CS_2$ , steeped in an aq.  $NH_4$  bath and washed. It is then pulverized, made into a pulp as in paper-making, and pressed into sheets.

**'Goldbeaters' skin and parchment.** A. EHRENREICH. Brit. 299,599, Oct. 11, 1927. The large intestine and wall of the stomach of sharks and similar fishes are washed, the veins are caused to disappear by compression or extraction, the material is limed for 2-4 days with addn. of a carbolate and immersed in a tanning liquid and then in a 1%  $HCl$  bath contg. also at least 4%  $NaCl$ . Tanning is then completed in a basic chrome alum bath or with a vegetable tanning material such as quebracho or sumach, or  $CH_2O$ , with or without alum, may be used. In production of drum skins, the large intestines are filled for 24 hrs. with shark oil or the like and sea salt and hung in the open air.

**Water-resistant animal glue.** CLARENCE E. HRUBESKY and FREDERICK L. BROWNE. U. S. 1,712,077, May 7. A glue compn. is prepd. from animal glue 100, water 225, paraformaldehyde 10 and a suitable acid such as oxalic acid 5-7 parts

### 30—RUBBER AND ALLIED SUBSTANCES

C. C. DAVIS

**New developments in the rubber industry. The Peachey process.** F. JACOBS *Caoutchouc & gutta-percha* **26**, 14,506-9 (1929).—A detailed description of the process and its latest developments. C. C. DAVIS

**Making rubber goods of latex by electrodeposition.** PAUL KLEIN. *Rubber Chem. & Technol.* **2**, 278-84 (1929).—See C. A. **23**, 2067. C. C. DAVIS

**The chemical constitution and the mechanical properties of rubber.** LOTHAR HOCK AND GUIDO FROMANDI. *Phys.-Chem. Inst., Univ. Giessen and Gummiwarenfabrik, Poppe & Co. Kautschuk* 5, 81-2(1929).—When synthetic isoprene-rubbers are treated electrically so that their viscosity, softening temp., mol. wt. and I no. increase to values similar to those of plantation rubber (cf. F., C. A. 23, 1009, 2323) their phys. characteristics also approach closely those of natural rubber. Moreover, a decrease in these consts. through elec. treatment of a high-grade natural rubber is accompanied by a loss of the most desirable properties of the rubber. This suggested that the poorer phys. characteristics of certain lower-grade com. rubbers might be assocd. with a lower I no., i. e., a lower degree of chem. unsatn. Purified rubber (by the Pummerer method) gave almost the theoretical I no. (372.8). Smoked sheet with 3.2% acetone ext. and 0.4% ash had an I no. of 348. Kongo rubber with 5.9% acetone extn. and 1.7% ash had an I no. of 329. In the latter case the acetone-sol. part had an I no. of 24, so that with 5.9% ext., 1.4 units were to be subtracted from the I no. of the rubber, giving 327.6 for the I no. of the rubber hydrocarbon. Dissolved in  $C_6H_6$ , filtered, pptd. twice with acetone and once with EtOH, and dried *in vacuo*, the I no. increased to 351.4. The same results were obtained with a Peruvian rubber. This treatment did not remove all impurities, and since the I no. approached so much nearer the theoretical value, it is doubtful whether there is any relation between the poorer phys. properties of the Congo rubber and its degree of unsatn., particularly since the elastic properties of rubber depend upon its colloidal state as well as upon its chem. constitution. This is also still more probable when the rubber is mixed with fillers, because the quality then depends upon the surface energy between the rubber and filler, which is governed by the phys. and chem. state of the rubber and the presence of non-rubber components.

C. C. DAVIS

**Titanium dioxide in the rubber industry.** RUDOLF DITMAR. *Kautschuk* 5, 79-81(1929).—The characteristics and behavior of  $TiO_2$  as a rubber compounding ingredient are described. Among the properties which may be of importance are its ability to soften rubber notably during milling and the limitations in the choice of accelerator to obtain a strictly white vulcanizate when it is used as the only white pigment.

C. C. DAVIS

**The effect of mixtures of crude ozocerite and "Agerite" on the aging of rubber mixtures.** F. KIRCHHOF. *Caoutchouc & gutta-percha* 26, 14,501-3(1929).—Ozocerite and "Agerite" fused together to a homogeneous mixt. give a product which combines the antioxidant and plasticizing properties of each component. Excellent results were obtained with a mixt. contg. 3-5% "Agerite" in ozocerite. Tests of vulcanized rubber which deteriorated rapidly with no antioxidant showed that its aging, judged by the deterioration of its phys. properties in air at 52° and at 75°, could be greatly improved by the addn. of the mixt. described, even when only enough of the mixt. was added to furnish 0.1% "Agerite" (by wt. of the rubber mixt.). This antioxidant effect was disproportionately great, for the 0.1% "Agerite" added in this form gave the same protection as 0.5% added alone, i. e., with ozocerite mixts. the same effect can be obtained as with 5 times as much Agerite added in the ordinary way. Photographic observations with ultra-violet light of the deteriorated samples showed that O penetrated less into the interior of the samples contg. ozocerite-Agerite than into those contg. none and the deterioration in phys. properties was proportional to this penetration.

C. C. DAVIS

**Pigment reinforcement.** R. W. LUNN. *Trans. Inst. Rubber Ind.* 4, 396-412(1929).—In the present investigation energy is chosen as the criterion of reinforcement. In the past, pigments have been compared by the resilient energy values of rubber mixts. contg. equal vols. of the pigments, but in the present paper the total energy is analyzed into that pertaining to the rubber and that to the pigment. Expressed mathematically, if  $E_A$  is the total energy of a mixt. contg. a pigment A,  $e_R$  the energy of the rubber component, and  $e_A$  the energy from  $x$  vols. of A, then  $E_A = e_R + e_A$ , and  $e_A/x$  is the energy from 1 unit vol. of pigment, this  $e_A/x$  value being a characteristic of the pigment. The object of the expts. was to det.  $e_A/x$  at various concns. of pigment and at various elongations up to rupture. If  $x$  vols. of pigment are added to a cube contg. 100 vols. of rubber, the new cube is  $(1 + x/100)$  times as large. Furthermore, if it is assumed that the pigment concentrates at 1 end of the enlarged cube, when this cube

is elongated the rubber and pigment elongate to the same degree, *e. g.*, when the cube is elongated 100%, both rubber and pigment elongate 100%. There are objections to this analysis, but the energy value of the pigment independent of the energy value of the rubber component may be readily detd. up to the breaking point. Pptd.  $\text{BaSO}_4$ ,  $\text{ZnO}$ , Thermatomic black and gas black were studied on this basis. An org. accelerator was not used in the base mixt., chiefly because of the influence of the pigments on it. The base mixt. was: rubber 100, S 3 and  $\text{PbO}$  10.3. The rubber was plasticized to an extreme degree to minimize the variations in milling necessary with the different pigments. To the base mixt. were added various proportions of the different pigments, and the resulting mixts. were vulcanized for a time and at a temp. which corresponded to that cure which gave the max. resilient energy for the base mixt. The results are recorded in graphical form, including the change in plasticity of rubber on mastication, the tensile strength, elongation, stiffness and energy of the base mixt. cured to different degrees, variations in the energy with concn. of the pigments, total energy-elongation relations, concn. of pigment-elongation relations, pigment energy per unit vol. of pigment, and the change of pigment energy per unit vol. with the concn. These results admit of certain general conclusions. Up to a high concn. C black increased the total energy,  $\text{ZnO}$  and Thermatomic black increased it much less and the maxima were at far lower concns., and pptd.  $\text{BaSO}_4$  increased it still less so, with its max. at a still lower concn. A comparison of the total energies at elongations below the breaking point shows that up to 50 vols. concn.,  $\text{BaSO}_4$  behaved like Thermatomic black and  $\text{ZnO}$ , while the C black showed much higher total energy values. With data on the base mixt. and on the loaded mixts., it was possible to cal. the energy due to the pigment, a vol. correction factor being used so that each mixt. was based on a unit vol. of rubber. The resulting curves of the pigments were similar to those showing total energy as a function of elongation. Finally the pigment energies per unit vol. of pigment are expressed graphically. In no case was there a sharp change in the mechanism of reinforcement as the proportion of pigment increased, the ultimate reinforcement per unit vol. declining progressively with increase in concn., with no evidence of agglomeration or of diln. With gas black and Thermatomic black, the reinforcement per unit vol. at definite elongations increased with increase in the concn., the effect being more marked with gas black. The reinforcement per unit vol. by  $\text{ZnO}$  increased less markedly above 10 vols. concn., while with  $\text{BaSO}_4$  above 20 vols. concn. it reached an approx. const. value at each elongation. Natural barytes would probably have behaved differently. The results show the sp. reinforcing power of the pigments at various concns. and elongations. The sp. reinforcing power of gas black and of Thermatomic black increased with the concn. and the elongation; with  $\text{ZnO}$  it increased in the same way but to a lesser degree, while the sp. reinforcing power of  $\text{BaSO}_4$  reached a const. value for each concn. and elongation. This suggests that there may be pigments which, beyond a crit. point, should exhibit a progressively diminishing reinforcing power. Curves of the ultimate energy values as the energy per unit vol. concn. of pigment show a trend toward 0 energy with increase of concn., suggesting that the pigment energy may become 0, *i. e.*, act as a diluent, but that neg. reinforcement does not occur, where the energy of the rubber component is diminished. The curves approach closely from 50 vol. concn. upwards, indicating that at high concns. no pigment has any notable advantage over any other pigment from the point of view of the energy imparted to a rubber mixt.

Isoprene and rubber. XIV. Degradation of rubber and gutta-percha. H. STAUDINGER AND H. F. BONDY. Univ. Freiburg. *Ann.* 468, 1-57 (1929); cf. C. A. 23, 2847.—An investigation is made of the degradation of rubber and gutta-percha

by heat. The materials used were a raw rubber contg. about 5% protein, rubber purified by Pummerer's method and gutta-percha obtained from a leaf gutta-percha, the  $\text{CCl}_4$  soln. being centrifuged from impurities, filtered and pptd. with  $\text{MeOH}$ . The viscosity of a  $\text{C}_6\text{H}_6$  or  $\text{PhMe}$  soln. of gutta-percha was not affected by boiling but  $\text{C}_6\text{H}_4\text{Me}_2$  or  $\text{C}_{10}\text{H}_{12}$  solns. of this substance, as well as all 4 solns. of raw and purified rubber, underwent an appreciable change of viscosity, the change being the greater, the higher the b. p. of the soln. It follows that the rubber undergoes degradation at fairly low temps., whereas gutta-percha withstands higher temps. Degradation of rubber in boiling  $\text{C}_6\text{H}_4\text{Me}_2$  produces gummy products, mol. wt. about 4200, while gutta-percha gives powdery substances, mol. wt. about 2500. Both products are regarded as being lower members of the 2 different series of which rubber and gutta-percha, resp., are complex members. In boiling  $\text{C}_{10}\text{H}_{12}$ , further degradation does not take place, although cyclization of the open-chain residues takes place to some extent. It is only at temps. above  $300^\circ$  that both decomp. to give identical products. The degradation of raw rubber appears to be inhibited somewhat by the presence of the protein at temps. up to  $142^\circ$ , but at higher temps. it follows a course similar to that observed with pure rubber. (With T. GERIGER.) The pyrogenic decompn. of gutta-percha begins at  $285\text{--}90^\circ$  and 11 mm., becomes vigorous at  $300\text{--}15^\circ$  and then ceases. Sixty g. of pure gutta-percha, heated 7 hrs. at  $300\text{--}10^\circ$  and 11 mm., gives 57% distillate and 40% residue; the latter is a *polycyclogutta-percha*,  $(\text{C}_8\text{H}_8)_x$ , mol. wt. in freezing  $\text{C}_6\text{H}_6$ , 1950, which contains 1 double bond (Br titration). Catalytic reduction with H and Ni gives a *hydro deriv.*,  $(\text{C}_{22}\text{H}_{42})_x$ , mol. wt., 1930,  $n_D^{20}$  1.5238. Raw rubber in boiling  $\text{C}_{10}\text{H}_{12}$  with HCl gives a *cyclorubber*, mol. wt. 2500, liquefying at about  $123^\circ$ , while gutta-percha gives a *cyclogutta-percha* indistinguishable from the rubber product. At lower temps., however, the 2 give different cyclization products. The *cyclorubbers* obtained in boiling  $\text{C}_6\text{H}_4\text{Me}_2$  and  $\text{PhMe}$  have mol. wts. 4000–12,900 and 14,000, resp. The *cyclogutta-perchas* obtained in boiling  $\text{C}_6\text{H}_4\text{Me}_2$ ,  $\text{PhMe}$  and  $\text{C}_6\text{H}_6$  have mol. wts. 2600–8100, 10,000 and about 8500, resp. Cyclization in  $\text{PhMe}$  at  $20^\circ$  gives different products with very high mol. wts. The heat-degradation products of rubber and gutta-percha are hemicolloids, mixts. of polyprenes with an av. mol. wt. of 10,000, which are relatively stable. This explains the considerable soly. of the products, the fact that the mol. wt. does not vary with concn. and the fact that the viscosities of solns. of the products are roughly proportional to the concn. Rubber, on the other hand, is a eucoioid, consisting of a mixt. of polyprenes having an av. mol. wt. of 100,000. Even a slight temp. elevation causes degradation. The macro-mol. is the colloid particle. The structures of the 2 compds. are discussed. Rubber contains about 1000 isoprene residues covalently united, and may be a *trans*-compd. The mol. of gutta-percha is smaller (about 300–500 isoprene residues), is more sym. and is possibly a *cis*-compd.

The nature of vulcanization. W. H. STEVENS. *J. Soc. Chem. Ind.* 48, 60–2T (1929); cf. C. A. 22, 1703.—A crit. review and discussion of exptl. facts known about vulcanization leads to the conclusion that vulcanization is the phys. manifestation of the chem. combination of rubber with S (or other elements), the mechanism of which is a reinforcement by the resultant S reaction product, with or without coexistent sorption. Thirty-five references are included. C. C. DAVIS

Vulcanization and the structure of rubber. HEINRICH LOEWEN. *Kautschuk* 5, 77–9 (1929).—A criticism of various features of an article by Lindmayer (cf. C. A. 23, 2323). C. C. DAVIS

The tackiness of unvulcanized rubber. T. L. GARNER. *Trans. Inst. Rubber Ind.* 4, 413–23 (1929).—The expts. are concerned chiefly with the action of light on raw rubber and on rubber to which has been added a small proportion by as little milling as possible, and are in part an amplification of previous work by other investigators. The tackiness of the samples was judged by their viscosities, a viscometer of the Ostwald type being used. In ordinary cases of exposure of raw rubber to air and light, tackiness and oxidation proceed concurrently, but it was possible to reduce the viscosity of a rubber soln. in the absence of O by exposure to ultra-violet light. Such a soln. gave on evapn. a depolymerized rubber which readily absorbed O. Introduction of a small

quantity of O into a tube contg. rubber in an atm. of N gave on exposure a rubber apparently as tacky as if exposed to air. The only difference was that part of the rubber was rendered insol. The action of light was in part polymerization and in part depolymerization, the extent of each depending upon the conditions. The presence of O was necessary for the formation of a tacky film, thus confirming expts. by Fry and Porritt (cf. *C. A.* 22, 4870). Little change in the soln. viscosity of rubber or its soln. took place when heated to 40° in the absence of light. Under the conditions of the expts., no insol. rubber was obtained by exposing solns. of uncompounded rubber in air, but in inert gases the formation of insol. rubber of the polymerized O-free type of Asano (cf. *C. A.* 19, 3616) was observed to increase with the time of exposure. The insol. rubber, formed when rubber protected by the addn. of an antioxidant was exposed to light, did not appear to be of this type, but rather the transparent oxidized rubber obtained by Asano. At the same time, the rate of oxidation, judged by the increase in acetone ext., did not progress to the same extent as with unprotected raw rubber. The protection against tackiness afforded by antioxidants is apparently unrelated to their value in preventing changes resulting from oxidation. Of importance in the technical use of antioxidants is the fact that they protect rubber in such a way that they prevent to some extent depolymerization and changes due to oxidation, thereby promoting the formation of an insol. polymerized rubber. This was not manifest in ordinary exposure. Thus an insol. layer of rubber was formed on the surface of the exposed rubber and the tackiness was destroyed. Consequently the use of much antioxidant in a rubber mixt. which must remain tacky where exposed in light in a factory for some time is inadvisable. On exposure to light, rubber mixts. contg. 1% antioxidant lost their surface tackiness much more rapidly than the corresponding mixts. contg. no antioxidant, the surfaces of the mixts. contg. antioxidant becoming dry and hard. The results suggest a *theory of tackiness*. When raw rubber is masticated, part of the globules burst and simultaneously the rubber hydrocarbon depolymerizes, which reduces the soln. viscosity. The tackiness of unmasticated rubber is due to the action of O upon the depolymerized hydrocarbon, and this tackiness cannot appear until depolymerization has occurred. Thus, on exposure of unmasticated rubber, the surface layer must first be depolymerized and then oxidized. In protecting rubber from depolymerization and subsequent oxidation, antioxidants permit the polymerizing action of light to become the predominant effect. Accordingly in a tacky rubber, repolymerization of the depolymerized-oxidized layer occurs to some extent, and the loss of tackiness is proportional to the extent of polymerization. In ordinary masticated rubber, the depolymerized-oxidized rubber is distributed throughout the mass, but in certain cases only the surface is affected. Tackiness is destroyed by substances which migrate to the surface and form greasy films, *e. g.*, stearic acid, or by substances which in any way promote the polymerizing action of light. Therefore, where tackiness is desired, conditions such as those described which favor this tendency must be eliminated.

C. C. DAVIS

**Exploitation of Euphorbia in South Africa: examination of the rosin and rubber.** W. SPOON AND M. VAN ROYEN. *Ber. Afdeel. Handelsmuseum Ver. Koloniaal Inst.* 34, 3-14(1928).—The rubber made from the latex of *E. dregeana* and other *Euphorbia* species has very little similarity to real rubber. From a sample of coagulum from the *E. dregeana* Bush rosin and rubber were prepd. The former was very impure, being of a soft and a hard texture and of apparently no value, while the latter was a thin soft mass. The *Hevea* culture need not fear any competition from this source.

**Rubber.** **RICHARD LATOUR.** Fr. 651,530, Sept. 12, 1927. Waste rubber which has been vulcanized in the cold with  $\text{CS}_2$  is recovered by shredding it to very thin sheets, removing the fatty substances, resins and S by sapon. with NaOH or KOH under steam pressure. Waste rubber which has been vulcanized by heating with free S is reduced to a powder, oils, fats or other solvents such as crude rubber, acetone, ether,  $\text{NH}_3$ , chloroform, etc., are added and the mass is devulcanized with steam, shredded and treated as in the first case.

**Rubber.** **THE ANODE RUBBER CO. (England) LTD.** Fr. 650,565, Mar. 7, 1928. Articles of rubber are made by bringing into contact with one another in a moist state and with or without pressure 2 or more pieces of material obtained directly by deposition, dipping, spreading, spraying or impregnating, from natural or artificial dispersions of rubber, etc., and drying or coagulating. Cf. C. A. 23, 2850.

**Rubber.** **THE B. F. GOODRICH CO.** Fr. 648,759, Dec. 27, 1927. Conversion products of rubber are obtained by heating it for a long time with a solvent for rubber such as benzine, a phenol and one of the following: HCl, HBr, org. sulfonyl chlorides, org. sulfonic acids, dil.  $\text{H}_2\text{SO}_4$  and trichloroacetic acid. The phenols include phenol, cresol, catechol, resorcinol, naphthols and *p*-chlorophenol. The products are plastic when heated and may be combined with fillers, pigments, etc.

**Rubber.** **VEREINGTE ALUMINIUM-WERKE. A.-G.** Ger. 472,662, Mar. 30, 1923. Glossy surfaces are produced on rubber goods by placing them on Al foil and rolling.

**Treating rubber latex.** **J. MCGAVACK** (to Naugatuck Chemical Co.). Brit. 298,628, Oct. 14, 1927. A reversible uncoagulated gel is formed by treating latex with an acid or, preferably, an alk. hydrosol of silicic acid in small quantity, either by direct addn. or by formation of the hydrosol in the latex. A gel which may be used for spreading, coating or other purposes forms in a few mins. Examples and details are given.

**Improving the aging properties of rubber.** **RUBBER GROWERS' ASSOCIATION, INC., G. MARTIN AND W. DAVEY.** Brit. 299,585, Sept. 26, 1927. Latex serum and an alkali, such as NaOH, KOH or  $\text{Na}_2\text{CO}_3$ , are added to a rubber mixt. before vulcanization (suitably in a proportion of about 5% and 1%, resp., based on the quantity of the rubber in the mixt.).

**Articles made from crude rubber.** **JAMES H. BURTON.** Fr. 649,565, Feb. 22, 1928. Crude rubber (latex prima, crepes, etc.) is heated with stirring in an autoclave with an alk. soln., and the granulations obtained are similarly heated with water, dried and pressed in heated molds.

**Rubber articles.** **THE NAUGATUCK CHEMICAL CO.** Fr. 651,615, Dec. 30, 1927. Rubber articles are produced directly from latex by dilg. the latex, adding substances which enable the aq. portion to filter more easily through the deposit as it forms, agitating and heating. Raw latex may be used to which stabilizers such as glue, Na oleate, casein or undecylenic acid emulsion may be added, the solid contents of the latex being 8-24, preferably 14%. To render filtering easy a Zn oxide or salt and a sulfide of Na, K, Li or  $\text{NH}_4$  are added, other substances which may be used are gel-forming colloids of buller solns. controlling the H-ion concn., substances liberating metallic ions and vulcanization accelerators.

**Compounding rubber with other materials.** **RAY P. DINSMORE** (to Goodyear Tire & Rubber Co.). U. S. 1,712,333, May 7. An emulsion of rubber is mixed with a suspension of a filler material such as pptd.  $\text{BaSO}_4$  and the rubber is coagulated on the filler, the product is washed free from water-sol. material and a rubber softener such as pine oil is added while the mass is still highly pasty and the product is then incorporated into a rubber mix upon the mill.

**Deposition of rubber.** **THE ANODE RUBBER CO. (England) LTD.** Fr. 650,566, Mar. 7, 1928. In the elec. deposition of rubber from aq. dispersions, the uniformity of thickness of the deposit is influenced by screens of insulating or poorly conducting material such as hard rubber, or celluloid or of conductive material to form equi-potential surfaces. The screens may be perforated or cut away, and if sep. chambers are used the screens are preferably disposed in the cathode chamber. Cf. C. A. 23, 2603.

**Deposition of rubber.** **THE ANODE RUBBER CO. (England) LTD.** Fr. 650,977, Mar. 17, 1928. In the direct deposition of a substance of the nature of rubber on porous supports imbibed, e. g., with a soln. of  $\text{CaCl}_2$ , or by electrophoresis, a coagulating agent is caused to act from the outside on the deposit before it is dried. This treat-

ment may be given once or several times before the full thickness of the deposit is reached.

**Deposition of rubber.** THE ANODE RUBBER CO., LTD. Fr. 651,672, Aug. 3, 1927. In the deposition of rubber on an anode support from aq. dispersions thereof, particularly from natural latex, by an elec. current, protective colloids are added to the dispersion. Thus, 6-12 g. of soft soap is added to 1 l. of latex contg. 30% of rubber.

**Deposition of rubber.** WM. A. WILLIAMS. Fr. 650,326, Dec. 27, 1927. See Brit. 293,095 (C. A. 23, 1527).

**Apparatus for coating articles with rubber by electrodeposition, etc.** G. F. WILSON (to Anode Rubber Co., Ltd.). Brit. 298,650, Oct. 13, 1927. Structural features.

**Drying rubber deposits.** A. SZEGVARI (to Anode Rubber Co., Ltd.). Brit. 298,483, Oct. 6, 1927. Articles formed by deposition of rubber from aq. dispersions are dried by applying to them a pervious material such as a fabric strip wrapping which exerts a compacting pressure. An app. is described.
